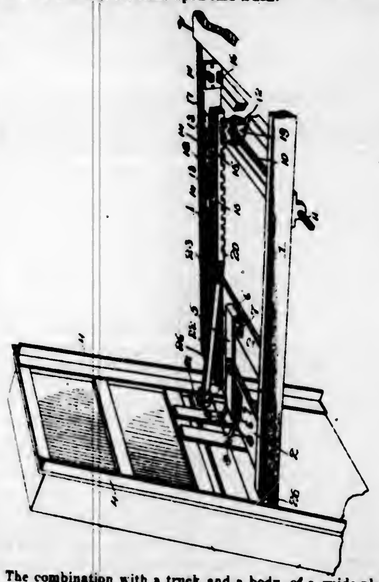
3. The combination with a truck and a movable body, of a guide-plate provided with angular ends secured to said truck, means connecting said guide-plate to said body, and means for moving said body off of or drawing the same upon said truck.



4. The combination with a truck and a body, of a guide-plate provided with beat ends, the ends of said guide-plate secured to said truck, means surrounding said guide-plate and secured to said body, and means for adjusting said body upon said truck.

5. The combination with a truck and a body, of a shaft journaled upon said body, a pinion provided with an annular flange fixedly secured to said shaft, a slidable rack-bar provided with a cut-out portion carried by said truck and meshing with said pinion, angular guiding means carried by said truck and engaging said rack-bar, and means connecting said rack-bar to said body.

6. In a dumping-vehicle, the combination with a truck and removable body carried thereby, of a pinion provided with an annular flange, carried by said truck, means for revolving said pinion, a rack-bar meshing with said pinion and carried by said truck and means connecting said body and rack-bar.

7. The combination with a truck and a body, of a guide-plate provided with beat ends, the ends of said plate engaging said truck, means connecting said plate to said body, and means for adjusting said body on said truck.

810,265. PEDESTAL-TABLE. GEORGE A. DAVIS, Grand Rapids, Mich. Filed Apr. 10, 1903. Serial No. 152,080.

Claim.—1. The combination with a table-top of a bridge-block secured thereto, a bridge secured to the bridge-block by two screws passing through the bridge into the bridge-block, a fulcrum between said fastening-screws, said fastening-screws and fulcrum so adjusted that the bridge may be tilted on said fulcrum, and pedestal-sections securely attached to the said bridges, substantially as described.

2. A pedestal extension-table comprising top sections and extension devices connecting the same, a two-part pedestal, bridge-blocks secured to each of the top sections, a bridge attached to the bridge-blocks of each section and to each of the sections of the pedestal, attaching means between each of said bridges and its bridge-blocks adapted to permit of a slight angular movement of the pedestal-section with respect to the top section to which it is attached, and a set-screw mounted on and extending through the bridge and engaging one of the adjoining and immediately-attached elements for adjustably tilting the pedestal-section with respect to the top section.

3. A pedestal extension-table comprising top sections and extension devices connecting the same, a two-part pedestal, bridge-blocks secured to each of the top sections, a bridge attached to the bridge-blocks of each section and to each of the sections of the pedestal, attaching means between each of said bridges and its bridge-blocks adapted to permit of a slight angular movement of the pedestal-section with respect to the top section to which it is attached, a metal plate secured upon one of the elements adjoining and immediately attached to one of said bridges, and a set-screw mounted on and extending through the bridge and bearing against said metal plate, whereby the pedestal-section may be tilted adjustably with respect to the top section.

4. In an extension-table, in combination with a sectional top, extension-supports therefor, and a sectional pedestal, of bridge-blocks secured to each of the top sections, a bridge secured to each of the pedestal-sections, attaching means extending through the bridges and engaging the bridge-blocks for loosely connecting the pedestal with the table-top and to permit of a slight angular movement of the pedestal-sections with respect to the sections of the top, and means extending through the bridges and engaging the bridge-blocks for tilting the pedestal-sections with respect to the sections of the top.

5. In an extension-table, in combination with a sectional top, extension-supports therefor, and a sectional pedestal, of bridge-blocks secured to each of the sections of the top, a bridge secured to each of the pedestal-sections, attaching means extending through the bridges and engaging the bridge-blocks for loosely connecting the pedestal with the table-top and to permit of a slight angular movement of the pedestal-sections with respect to the sections of the top, and adjustable means extending through the bridges and engaging the bridge-blocks for adjustable tilting the pedestal-sections with respect to the sections of the top.

810,266. LAMP-GUARD. EDWARD C. DICKERSON, Elgin, Ill. Filed Feb. 4, 1904. Serial No. 191,954.

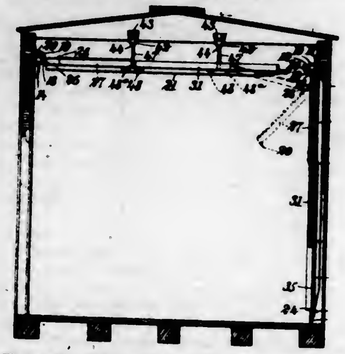
Claim.—1. An electric-light-lamp guard formed from sheet metal and having end collar portions and flat longitudinal ribs formed integral with said collar portions, and lying substantially in radial planes passing through the longitudinal axis of the guard.

2. An electric-light-lamp guard formed of two parts, each part formed from a single piece of sheet metal and having end collar portions and flat longitudinal ribs formed integral with said collar portions and lying substantially in radial planes passing through the longitudinal axis of the guard.

3. An electric-light-lamp guard formed of two parts, each part being formed from a single piece of sheet metal having end collar portions and flat longitudinal ribs formed integral with said collar portions and lying in substantially radial planes passing through the longitudinal axis of the guard, and being outwardly bowed, one set of said collar portions being adapted to engage the lamp-socket for holding the guard in position.

810,267. GRAIN-DOOR. JOSEPH H. DRAKE, Blue Rapids, Kans. Filed Feb. 27, 1905. Serial No. 247,498.

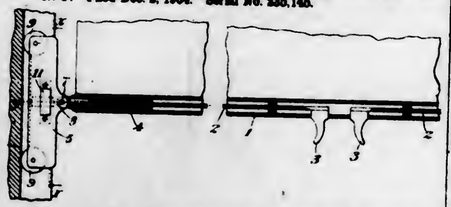
Claim.—1. The combination with a car having a door-opening, of a hollow guide extending longitudinally of the car above the opening, a supporting member fixed upon the door and being movable through and rotatable in the guide, and an arm extending from the support and having means overlying and contacting with the guide during the rotation of the supporting member.



2. The combination with a car having a door-opening, of a hollow guide extending longitudinally of the car above the opening, a supporting member fixed upon the door and being movable through and rotatable in the guide, an arm extending from the support outside the guide, and a roll upon the arm contacting with the guide throughout the rotation of the supporting member.

3. A grain-car door, comprising a frame having side members and a cross-bar connecting the side members between their ends, and having its ends projecting beyond the same, a lower fixed door-section secured to the side members of the frame at one side of the cross-bar, and an upper door-section hinged at its upper edge to the frame and having its free lower edge engaging the cross-bar.

810,268. CURTAIN-FIXTURE. CLIFFORD H. DUNN, New York, N. Y. Filed Dec. 3, 1904. Serial No. 235,145.



Claim.—1. In a fixture for a self-righting curtain the combination with a shade, of a curtain-stick, head-pieces movably secured to said stick and having antifriction-surfaces for contact with the window-frame, friction devices movably mounted in said head-pieces and adapted to engage the side of the groove in the window-frame, and means whereby the movement of the head-pieces on the stick withdraws the friction devices from operation, substantially as described.

2. In a fixture for a self-righting curtain, the combination with a shade of a curtain-stick comprising outwardly-pressed members, head-pieces movably secured to the ends of said members and having antifriction-surfaces for contact with the window-frame, movable friction devices carried by said head-pieces independent of the stick and adapted to engage the groove in the window-frame, and means whereby the movement of the head-pieces on the stick withdraws the friction devices from operation.

3. In a fixture for a self-righting curtain, the combination with a shade, of a curtain-stick comprising outwardly-pressed members, head-pieces movably secured to the ends of said members and having antifriction-surfaces for contact with the window-frame, friction devices movably mounted in said head-pieces independent of the stick and adapted to engage the side of the groove in the window-frame, means whereby the movement of the head-pieces on the stick withdraws the friction devices from operation, and whereby the inward movement of the curtain-stick members retracts the friction devices from operation, substantially as described.

4. In a fixture for a self-righting curtain, the combination with a shade, of a curtain-stick, head-pieces movably secured to said stick and having antifriction-surfaces for contact with the window-frame, friction devices movably mounted in said head-pieces and adapted to engage the groove in the window-frame, the friction devices having beveled surfaces and the curtain-stick having corresponding beveled surfaces whereby the movement of the head-pieces on the stick withdraws the friction devices from operation, substantially as described.

5. In a fixture for a self-righting curtain, the combination with a shade, of a curtain-stick comprising outwardly-pressed members, head-pieces movably secured to the ends of said members and having antifriction-surfaces for contact with the window-frame, friction devices movably mounted in said head-pieces and adapted to engage the groove in the window-frame, the friction devices having beveled surfaces and the curtain-stick having corresponding beveled surfaces, whereby the movement of the head-pieces on the stick withdraws the friction devices from operation, and means whereby the inward movement of the curtain-stick members retracts the friction devices within the head-pieces, substantially as described

6. In a fixture for a self-righting curtain, the combination with a shade, of a curtain-stick comprising pinch-handled outwardly-pressed members, head-pieces pivoted to the outer ends of said members and having antifriction-rollers mounted therein, a centrally-disposed friction device adapted to engage the groove in the window-frame, beveled surfaces on the friction devices and corresponding beveled surfaces on the curtain-stick whereby the movement of the head-pieces on the stick withdraws the friction device from operation, substantially as described.

7. In a fixture for a self-righting curtain, the combination with a shade of a curtain-stick comprising outwardly-pressed members, head-pieces movably secured to the ends of said members and having antifriction-surfaces for contact with the window-frame, a friction device movably mounted in said head-pieces and adapted to engage the groove in the window-frame, said friction devices having beveled surfaces and said stick having correspondingly beveled and obliquely-set terminals coacting with said beveled surfaces of the friction devices whereby the friction devices are withdrawn from operation when the head-pieces are tilted on the stick or when inward movement is imparted to the curtain-stick members, substantially as described.

8. In a fixture for a self-righting curtain, the combination with a shade, of a curtain-stick comprising pinch-handled outwardly-pressed members, head-pieces pivotally secured to the outer ends of said members, which members have slotted connections therewith, antifriction-surfaces on said head-pieces and centrally-disposed friction devices movably connected to the head and means whereby the friction devices are withdrawn from operative position when the head-pieces are tilted on the stick and when the curtain-stick members are moved inwardly, substantially as described.

9. In a fixture for a self-righting curtain, the combination with a shade, of a curtain-stick comprising pinch-handled outwardly-pressed members, head-pieces pivotally secured to the outer ends of said members, which members have slotted connections therewith, antifriction-surfaces on said head-pieces, centrally-disposed friction devices having beveled surfaces thereon, correspondingly beveled and obliquely-set terminals on said curtain-stick members whereby the friction devices are withdrawn from operative position when the head-pieces are tilted on the stick or when the curtain-stick members are moved inwardly, substantially as described.

10. In a fixture for a self-righting curtain, the combination with a shade, of a curtain-stick, a head-piece tiltable relative to the stick, a spring-pressed holding member adapted to engage the side of the groove in the window-frame, and means whereby the tilting of the head-piece relative to the stick withdraws the holding member from operation.

11. In a curtain-fixture, the combination with a shade, of a curtain-stick, a head-piece tiltable relative to the stick, a holding member adapted to engage the side of the groove in the window-frame, and means whereby the tilting of the head-piece withdraws the holding member from operation.

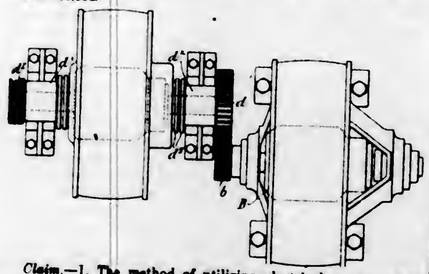
12. In a fixture for a self-righting curtain, the combination with a shade, of a curtain-stick, a head-piece tiltable relative to the stick, a holding member adapted to engage the side of the groove in the window-frame, means for withdrawing the holding member from operation, and means operatively associated with said last-mentioned means rendering the same automatically operable by the tilting of the head.

13. In a curtain-fixture, a longitudinally-movable stick, a head therefor, a holding device adapted to engage the side of a groove of a window-frame, said holding device being slidably mounted in the head and having a loose connection with the stick permitting transverse movement thereof relative to the stick, and means whereby the inward and outward movements of the stick relative to the head will impart like transverse movements to the holding device.

14. In a curtain-fixture, a longitudinally-movable stick, a head therefor, a spring-actuated holding device adapted to engage the side of a groove of a window-frame, said holding device being slidably mounted in the head for transverse movement relative to the stick, and a slidable engagement between the holding device and stick whereby the inward and outward movements of the stick relative to the head will impart like transverse movements to the holding device.

15. In a curtain-fixture, a longitudinally-movable stick, a head therefor, a holding device adapted to engage the side of a groove of a window-frame, said holding device being slidably mounted in the head for transverse movement relative to the stick, the said stick and holding device having a loose connection with one another, and one of said last-mentioned members having an inclined portion at said connection whereby inward and outward movement of the stick will impart like transverse movements to the holding device.

810,269. METHOD OF OPERATING ELECTRIC MOTORS. ARTHUR C. EASTWOOD, Cleveland, Ohio. Filed July 24, 1903. Serial No. 166,864.



Claim.—1. The method of utilizing electrical energy, which consists in first transforming electrical energy from a source of supply into mechanical energy, transforming said mechanical energy into electrical energy, transforming a portion of said electrical energy into mechanical energy to drive a load and employing another portion of said electrical energy to directly control the rate at which electrical energy from the source of supply is transformed into mechanical energy, substantially as described.

2. The method of utilizing electrical energy, the same consisting in first transforming electrical energy from a source of supply into mechanical energy, transforming said mechanical energy into electrical energy, transforming a portion of said electrical energy into mechanical energy to drive a load, and causing the remainder of said electrical energy to automatically and directly determine the rate at which mechanical energy is utilized, substantially as described.

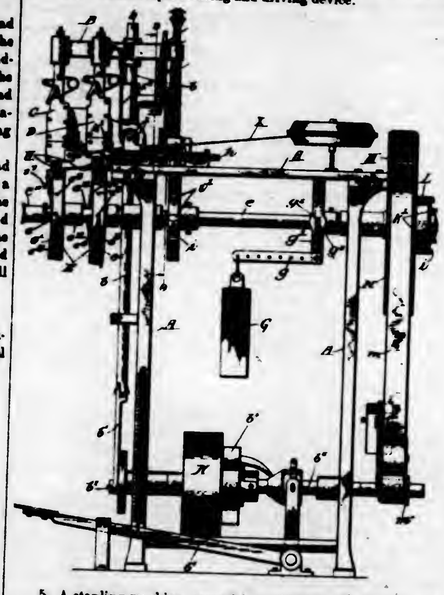
810,270. MACHINE FOR USE IN MAKING BASKETS OR OTHER RECEPTACLES. JOHN ERLUND, St. Joseph, Mich., and ENOS L. WALKER, St. Louis, Mo. Filed Nov. 16, 1903. Serial No. 181,395.

Claim.—1. A stapling-machine comprising a rotary form mounted to shift axially during its rotation and means for automatically producing the axial shift.

2. A machine for making band-like articles, comprising an intermittently-rotated form mounted to shift axially during its rotation and means for automatically producing the axial shift.

3. A stapling-machine, comprising an intermittently-rotated form provided with two rows of clench-blocks, each row extending circumferentially of the form in an irregular line, suitable staple forming and driving devices, said form being mounted to shift axially during its rotation, and means for automatically producing the axial shift whereby the said clench-blocks are successively presented in proper position beneath the staple forming and driving devices.

4. A machine for making band-like articles slightly higher at two opposite points than at intermediate points, comprising a rotary form provided with a plurality of clench-blocks, the said clench-blocks extending circumferentially of the form in an irregular line, suitable staple forming and driving devices, said form being mounted to shift axially during its rotation, and means for automatically producing the axial shift whereby said clench-blocks are successively presented to said staple forming and driving device.



5. A stapling-machine, comprising suitable staple forming and driving devices, a rotary form having a truly circular circumference, said form being mounted to shift axially during its rotation and means for automatically producing the axial shift.

6. A machine for making band-like articles slightly higher at two opposite points than at intermediate points, comprising suitable staple forming and driving devices, an intermittently-rotated form mounted to shift axially during its rotation, and means for automatically producing the axial shift whereby the staples are inserted at points equidistant, or substantially equidistant, from the edges of said article.

7. A stapling-machine, comprising suitable staple forming and driving devices, an intermittently-rotated form mounted to shift axially during its rotation, and means for automatically producing the axial shift, said form being provided with an axially-adjustable handle and a plurality of pivoted arms for throwing the completed article off the form.

8. A stapling-machine, comprising staple forming and driving devices, an intermittently-rotated form provided with an axially-adjustable handle, and means operated thereby for throwing the completed article off the form, and a tilting guide for feeding the materials onto said form.

9. A stapling-machine, comprising suitable staple forming and driving devices, a rotary form mounted to shift axially during its rotation, and a tilting guide for feeding the materials onto said form and means for automatically producing the axial shift.

10. A stapling-machine, comprising suitable staple forming and driving devices, a rotary form, a stop device adapted and operative to automatically and intermittently interrupt the rotation of said form, and a trip device adapted and operative to automatically prevent said stop device from releasing said form immediately after the driving of the last staples.

11. A stapling-machine, comprising suitable staple forming and driving devices, a rotary form, a driven member, a yielding and continuously-acting frictional connection between said driven member and the rotary form, and a stop device for automatically and intermittently resisting and interrupting the rotary motion imparted through said connection from said driven member to said form, together with power-transmitting connections for operating said stop device at predetermined intervals, whereby the work is given an intermittent feeding movement and is always stationary while being

acted on; a power-operated automatic trip device adapted and operative to automatically prevent a continuance of said intermittent motion after the final operation is performed by the machine upon the work or article, and means for manually resetting the mechanism upon the substitution of fresh work for the finished article; and power-transmitting connections, independent of said continuously-acting frictional connection, for operating said trip device, and means for performing successive fastening operations on the work.

12. A stapling-machine, comprising suitable staple forming and driving devices, a rotary form adapted and operative to automatically shift axially during its rotation, a driven member, a yielding and continuously-acting frictional connection between said driven member and said form, and a stop device adapted and operative to automatically and intermittently resist and interrupt the rotary motion imparted to said form through said connection from said driven member, together with power-transmitting connections for operating said stop device at predetermined intervals, whereby the work is given an intermittent feeding movement and is always stationary while being acted on; a power-operated automatic trip device adapted and operative to automatically prevent a continuance of said intermittent motion after the final operation is performed by the machine upon the work or article, and means for manually resetting the mechanism upon the substitution of fresh work for the finished article; and power-transmitting connections, independent of said continuously-acting frictional connection, for operating said trip device and means for performing successive fastening operations on the work.

13. A stapling-machine, comprising suitable staple forming and driving devices, a rotary form provided on its inner face with a cam-like surface, a roll mounted in stationary bearings and adapted to engage said cam-like surface, and thereby cause the form to automatically shift axially during its rotation, and a pressure device for maintaining said form in contact with said roll.

14. A stapling-machine comprising suitable staple forming and driving devices, a rotary form mounted to shift axially during its rotation, means for automatically producing the axial shift, a spring-held pivoted guide for feeding the materials to said form, a driven member, a yielding frictional connection between said driven member and said form, and a stop device adapted to automatically and intermittently interrupt the rotary motion imparted to said form through said connection from the driven member.

15. A stapling-machine, comprising a rotary work-holder, a driven member, a yielding and continuously-acting frictional connection between said rotary work-holder and said driven member, and a stop device adapted and operative to automatically resist and interrupt the rotary movement imparted to said rotary work-holder through said connection from said driven member, together with power-transmitting connections for operating said stop device at predetermined intervals, whereby the work is given an intermittent feeding movement and is always stationary while being acted on; a power-operated automatic trip device adapted and operated to automatically prevent a continuance of said intermittent motion after the final operation is performed by the machine upon the work or article, and means for manually resetting the mechanism upon the substitution of fresh work for the finished article; and power-transmitting connections, independent of said continuously-acting frictional connection, for operating said trip device and means for performing successive fastening operations on the work

16. A stapling-machine, comprising suitable staple forming and driving devices, an intermittently-rotated form mounted to shift axially during its rotation, means for producing the axial shift, said form being provided with a pivot-hook having a spring adapting it to reach over and clamp the desired materials upon the said form.

17. A stapling-machine, comprising a rotary form, said form being provided with a pivoted hook composed of yieldingly-connected sections, said hook being also provided with a spring, whereby the hook may be distended and employed for clamping the desired materials upon the said form.

18. A stapling-machine, comprising suitable staple forming and driving devices, a form mounted to shift axially during its rotation, means including a roll and a cam-surface on the form for shifting the form in one direction, and means including a weight and a bell-crank-shaped lever for shifting the form in the other direction.

19. A stapling-machine comprising a rotary form, suitable staple forming and driving mechanism, and power-operated means for causing relative shift between the form and stapling mechanism in the direction of the axis of said form during the rotation of the form.

20. A machine comprising suitable means for forming and driving fastening devices, a rotary form for holding the work, a driven member, two frictional connections serving as medium of power-transmitting connection between said driven member and form, one of said connections being normally open and manually controlled, the other frictional connection being normally and at all times closed, and a positive stop device for intermittently interrupting the rotation of said form, whereby the continuous rotation of said driven member is converted into intermittent rotary motion on the part of said form by intermittingly presenting a positive resistance to the power transmitted through said connection, together with power-transmitting connections for operating said stop device at predetermined intervals, whereby the work is given an intermittent feeding movement and is always stationary while being acted on; a power-operated automatic trip device adapted and operative to automatically prevent a continuance of said intermittent motion after the final operation is performed by the machine upon the work or article, and means for manually resetting the mechanism upon the substitution of fresh work for the finished article; and power-transmitting connections, independent of said continuously-acting frictional connection, for operating said trip device and means for performing successive fastening operations on the work.

21. A machine comprising suitable means for forming and driving fastening devices, suitable means for holding and feeding the work, a driven member, a frictional connection arranged as medium of power-transmitting connection between the said driven member and the said means for holding and feeding the work, and a positive stop device for intermittently interrupting the movement of said means, whereby the continuous rotation of said driven member is converted into intermittent motion on the part of said means by intermittently presenting a positive resistance to the power transmitted through said connection, together with power-transmitting connections for operating said stop device at predetermined intervals, whereby the work is given an intermittent feeding movement and is always stationary while being acted on; a power-operated automatic trip device adapted and operative to automatically prevent a continuance of said intermittent motion after the final operation is performed by the machine upon the work or article, and means for manually resetting the mechanism upon the substitution of fresh work for the finished article; and power-transmitting connections, independent of said continuously-acting frictional connection, for operating said trip device and means for performing successive fastening operations on the work.

22. A machine for use in making baskets, comprising suitable means for forming and driving fastening devices, a rotary work-holding form, a driven member, and a frictional connection serving as medium of power-transmitting connection between said driven member and the rotary form, said connection comprising flat frictional surfaces clamped together with the proper degree of pressure by adjustable set-screws, whereby the continuous rotation of said driven member is converted into intermittent motion on the part of said form by intermittently presenting a positive resistance to the power transmitted through said connection, together with power-transmitting connections for operating said stop device at predetermined intervals, whereby the work is given an intermittent feeding movement and is always stationary while being acted on; a power-operated automatic trip device adapted and operative to automatically prevent a continuance of said intermittent motion after the final operation is performed by the machine upon the work or article, and means for manually resetting the mechanism upon the substitution of fresh work for the finished article; and power-transmitting connections, independent of said continuously-acting frictional connection, for operating said trip device and means for performing successive fastening operations on the work.

23. A machine comprising suitable means for forming and driving fastening devices, a rotary form for holding and feeding the work, a driven member, a frictional connection arranged as medium of power-transmitting connection between said driven member and form, and a positive stop device for intermittently interrupting the rotation of said form, whereby the continuous rotation of said driven member is converted into intermittent motion on the part of said form by intermittingly presenting a positive resistance to the power transmitted through said connection, together with power-transmitting connections for operating said stop device at predetermined intervals, whereby the work is given an intermittent feeding movement and is always stationary while being acted on; a power-operated automatic trip device adapted and operative to automatically prevent a continuance of said intermittent motion after the final operation is performed by the machine upon the work or article, and means for manually resetting the mechanism upon the substitution of fresh work for the finished article; and power-transmitting connections, independent of said continuously-acting frictional connection, for operating said trip device and means for performing successive fastening operations on the work.

24. In a machine of the character described, the combination of means for holding the work, means for driving fastening devices into the work, a driven member, a frictional power-transmitting connection, and a positive stop device adapted and operative to intermittently offer a positive resistance to the power transmitted from said driven member through said connection to produce relative intermittent feeding movement on the part of said means for holding the work and the means for driving the fastening devices, together with means for operating said stop device at predetermined intervals, whereby the work and means for driving the fastening devices have the said relative feeding movement and are always relatively stationary when the work is being acted on; a power-operated automatic trip device adapted and operative to automatically prevent a continuance of said intermittent motion after the final operation is performed by the machine upon the work or article, and means for manually resetting the mechanism upon the substitution of fresh work for the finished article; and power-transmitting connections, independent of said continuously-acting frictional connection, for operating said trip device and means for performing successive fastening operations on work.

25. A machine for use in making baskets, comprising a rotatable basket-form for the work, a power-driven member adapted for continuous rotation, and a frictional connection and a positive stop device adapted and operative to convert the continuous rotation of said member into intermittent rotation on the part of said form, said stop device operating independently of the work on the form, and independently of the connection between one member of the frictional connection and the said power-driven member, to intermittently stop the rotation of the other member of the frictional connection.

26. In a machine for use in making receptacles, comprising means for holding the work and driving fastening devices in the same, a drive-shaft, two independent power-transmitting means extending between said drive-shaft and the said means for holding the work and driving fastening devices, and an automatic positive stop device also operated by one of said power-transmitting means, the other power-transmitting means including a driven shaft intermittently interrupted in its rotation by said stop device, a member fixed to said shaft, a pulley loose on said shaft, means for holding the pulley and member in tight frictional connection, and a belt connecting said pulley with said drive-shaft.

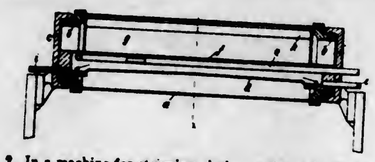
27. A machine for use in making receptacles, comprising means for holding the work and driving fastening devices in the same, power-transmitting connections including a frictional connection and a shaft for operating one or more of the operative parts of said means, an automatic positive stop device for intermittently interrupting the rotation of said shaft, and connections independent of the work, and independent of the said frictional connection, for operating said stop device, said frictional connection comprising one member fixed to said shaft, another member loose on said shaft, and means for holding the two members in tight frictional connection.

28. In a machine for use in making baskets, endwise bodily-movable means for holding the work, power-transmitting connections including a frictional connection, a positive stop device for intermittently interrupting the motion communicated through said frictional connection, and connections independent of the work, and independent of the said frictional connection, for operating said stop device, said frictional connection comprising a shaft, a member loosely mounted on said shaft, a member fixed to said shaft, and means for holding said members in tight frictional connection with each other.

29. In a machine for making baskets, and in combination with suitable means for holding the work and driving fastening devices in the same, a frictional power-transmitting connection, a positive stop device for automatically interrupting the motion transmitted through said frictional connection, and connections independent of the work, and independent of said frictional connection, for operating said stop device, said frictional connections comprising a shaft, a member loose on said shaft, a member fixed to said shaft, and means for holding said members in tight frictional connection with each other.

810,271. MACHINE FOR STEAMING CLOTH. GUSTAV B. GRALOW, Crimmitschau, Germany, assignor of one-half to Ketting & Braun, Crimmitschau, Saxony, Germany. Filed Apr. 5, 1905. Serial No. 254,602.

Claim.—1. In a machine for steaming cloth a perforated cylinder in combination with a scraper adapted to remove from its inner surface the particles of the condensing water substantially as described.



2. In a machine for steaming cloth a perforated cylinder with end rings revolving in stationary caps with ball-races in combination with a resilient scraper adapted to remove from its inner surface the particles of the condensing water substantially as described.

3. In a machine for steaming cloth a perforated cylinder in combination with a stationary scoop longitudinally extending through the cylinder, provided with a bottom inclined from the middle toward both ends, and carrying a resilient scraper adapted to remove from the inner surface of the cylinder the particles of the condensing water, substantially as described.

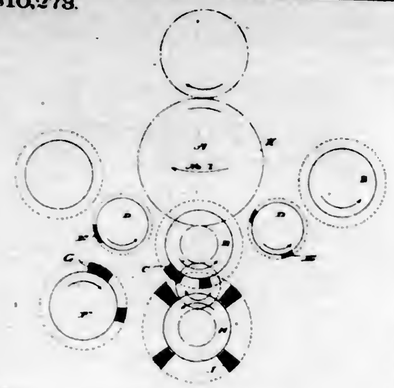
810,272. CRATE. DAVID GIBBS, Livonia, N. Y. Filed Apr. 4, 1905. Serial No. 253,853.

Claim.—As an article of manufacture, a crate comprising a bottom, sides connected with the bottom for movement into and out of operative position, said sides having vertical stripe against their inner faces adjacent to their ends, ends hinged to the bottom for movement to rest at times thereupon and at times to extend upwardly therefrom and to rest against the inner faces of the stripe when the sides are in erect position, long hooks pivotally connected with one of the sides inwardly of its end stripe and in spaced relation thereto, and hook-receiving eyes carried by the other side inwardly of its end stripe and in spaced relation thereto, said hooks being adapted for engagement in the eyes and when in such position, being arranged to lie against the inner faces of the ends to prevent inward movement of the latter.

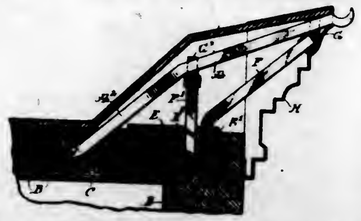
810,273. NAPPING-MACHINE. HARRY S. GREENE, Woonsocket, R. I. Filed May 24, 1905. Serial No. 261,960.

Claim.—In a napping-machine, the combination with a drum equipped with napping-rollers and also with comparatively large rollers bearing card-clothing and alternating with the napping-rollers and having their axes arranged in a common circle with the axes of the napping-rollers; of a roller bearing wire-clothing and arranged outside the drum in a position to clean the card-clothing of the comparatively large rollers on the drum, a roller having longitudinal strips of material for cleaning the card-clothing of the napping-rollers of the drum; said strips being arranged to clear the comparatively large rollers and having long wires adapted to reach to and engage the card-clothing of the small napping-rollers, and a positive driving connection intermediate the drum and the second-mentioned cleaning-roller for driving the latter by the former.

810,273.



810,274. SUPPORT FOR HOISTING DEVICES. LOUIS GREENEY, New York, N. Y. Filed Oct. 14, 1905. Serial No. 282,786.



Claim.—1. A hoist-supporting device for buildings, comprising a hook-bar, and means for permanently securing the hook-bar to the building at the roof thereof, the hook of the said hook-bar projecting through the cornice of the building.

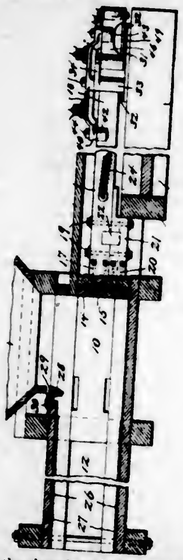
2. A hoist-supporting device for buildings, comprising a hook-bar having its outer end terminating in a hook and having its inner end forked and secured to roof-beams, the hook projecting beyond the face of the cornice of the building, a roof-beam chair and braces seated in the sockets formed therein.

3. A hoist-supporting device for buildings, comprising a hook-bar having its outer end terminating in a hook and having its inner end forked and secured to roof-beams, the hook projecting beyond the face of the cornice of the building, a roof-beam chair and braces seated in the sockets formed therein, each brace having a shoe for the hook-bar to rest on.

810,275. HAY-PRESS. THOMAS R. HACKWORTH, South Pittsburg, Tenn. Filed Feb. 24, 1905. Serial No. 247,169.

Claim.—1. In a device of the class described, a press-box having a baling-box extending from one end and a supporting base-frame extending from the other end, a plunger for reciprocation in said press-box and having an operating-beam extending therefrom, a spring connected to yieldably maintain said beam and plunger in withdrawn position, a stud extending from said base-frame in central alinement with said press-box, a trip-arm pivoted at one end to said base-frame with the body of trip-arm in alinement with the body of the beam and with a transverse recess near its free end, means for connecting the free end of said beam to the free end of said trip-arm and in central alinement therewith, and a crank-arm mounted for rotation and provided with a roller at the free end for engaging the body of said trip-arm centrally and passing through said recess at the terminal of the forward stroke to release the trip-arm.

2. The combination in a device of the class described, of a press-box having a spring-controlled plunger and operating-beam mounted for reciprocation, and with a base-frame extending rearwardly therefrom, a trip-arm pivoted by one end and movably connected by the free end of said beam and provided with a transverse recess near said free end, a crank-arm having depending ends terminating in semi-globular hubs, rollers having semispherical cavities engaging said hubs and maintained rotatively thereon by binding-bolts, said rollers engaging said trip-arm and passing through said recess at the end of the stroke, whereby the lateral strains are borne by the hubs and the pivot-pins relieved from lateral strains.

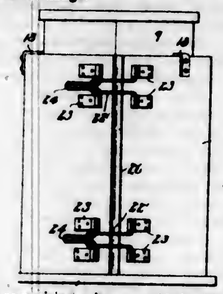


3. In a device of the class described, a press-box having a baling-box extending from one end and a supporting base-frame extending from the other end and provided with a transverse stop, a plunger mounted for reciprocation in said press-box, a beam extending rearwardly of said plunger and provided with a transverse recess, a stop member rigidly secured to said beam and bearing against said base-stop when the plunger is in withdrawn position and provided with a transverse recess for registration with the recess in said beam, a transverse chock for fitting in said recesses, a spring for holding said beam and its attached stop member yieldably in withdrawn position, and tripping means for moving said beam and its attached plunger and stop member in one direction and releasing the same for the return movement by the action of said spring.

4. In a device of the class described, a press-box having a baling-box extending from one end and a supporting base-frame extending from the other end and provided with a transverse stop, a plunger for reciprocation in said press-box and having an operating-beam extending therefrom provided with a transverse recess, a stop member rigidly secured to said beam for bearing against said base-stop when the beam is in withdrawn position and provided with a transverse recess for registration with the recess in said beam, a transverse chock fitting in said recess, a spring connected to yieldably maintain said beam and plunger in withdrawn position, a stud extending from said base-frame in central alinement with said press-box, a trip-arm pivoted by one end to said stud with the body of the trip-arm opposite the body of the beam and with a transverse recess near its free end, straps attached to opposite sides of the free end of said beam and pivoted to the opposite sides of the free end of said trip-arm, and a crank-arm mounted for rotation and provided with a roller at its free end for engaging said trip-arm and passing through said recess at the terminal of the forward stroke to release the trip-arm.

810,276. MOLD FOR DRAIN OR SEWER PIPES. JAMES B. HILL, Findlay, Ohio. Filed Aug. 30, 1905. Serial No. 276,695.

Claim.—1. A mold comprising a base provided with an upwardly-extending flange, a sectional inner shell engaging the adjacent walls of the flange, a sectional expanding ring resting on the base and serving to clamp the inner shell in engagement with said walls, an expansible outer shell of less height than the inner shell and spaced from the latter to favor an intermediate molding-chamber, inwardly-extending lugs secured to the upper end of the outer shell and adapted to engage the exterior walls of the inner shell, loops pivotally mounted on one longitudinal edge of the outer shell, and hooks pivotally mounted on the adjacent longitudinal edge of the shell and adapted to engage said loops for clamping the outer shell in engagement with the flange.



2. A mold comprising a base provided with an upwardly-extending flange, a sectional inner shell engaging said flange, a flat sectional expanding ring engaging the interior walls of the inner shell and provided with alined inwardly-extending operating-handles, a retaining-collar provided with a seating-groove for the reception of the upper end of the inner shell, a split expansible outer shell spaced from the inner shell, to form an intermediate molding-chamber and having one longitudinal edge thereof formed with a vertical groove adapted to receive the adjacent longitudinal edge of the outer shell, and means for clamping the outer shell in engagement with the flange.

810,277. ATTACHMENT FOR CHAIRS. VIRGINIA M. HOLLYDAY, Baltimore, Md. Filed Apr. 4, 1905. Serial No. 253,763.

Claim.—1. A double seat of the vis-à-vis type having a central support between the seats proper, the same being provided with two passages serving as hearing and speaking tubes and having open mouths which project rearward on opposite sides of the central support so that each set of such mouths is available for hearing and speaking by the person occupying the contiguous seat, substantially as described.

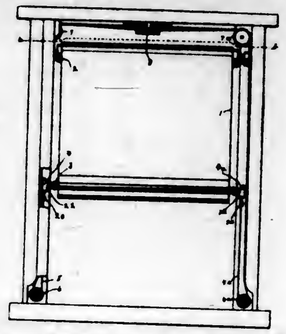
2. An improved article of furniture, comprising a double seat having backs and an intervening or middle portion forming a continuation thereof, and a horizontal bar C forming a rigid attachment of such middle portion, and provided with passages opening on opposite sides of the bar and arranged for convenience of use for hearing and speaking in the manner described.

3. A seat comprising two seats proper and a rigid vertical frame intervening the same and having at the top lateral projections each provided with a passage opening at one end on the rear side thereof or toward the back of the contiguous seat, the opposite end of the passage opening on the other side of the frame, as and for the purpose specified.

810,278. CURTAIN-FIXTURE. CHARLES L. HOPKINS, Albany, N. Y., assignor to The Curtain Supply Company, Newark, N. J., a Corporation of New Jersey. Filed Aug. 21, 1903. Serial No. 170,572.

Claim.—1. In a curtain-fixture, the combination of a window-frame, a roller mounted therein, a spring for rotating the roller, a curtain winding upon said roller, a winding-drum mounted upon the window-frame, a spring for rotating the winding-drum, a tape, winding upon said winding-drum, the end of the tape, being secured to the curtain, the power of the springs being opposed the one to the other whereby the curtain and tape are maintained in a tense condition, substantially as described.

2. In a curtain-fixture, the combination with a curtain, of flexible connections secured to the lower edge of the curtain, a rotatable drum upon which the flexible connections wind, means for impeding the rotation of the drum in one direction, the said drum having free rotation in the opposite direction, and spring means for rotating the drum, for the purpose set forth.

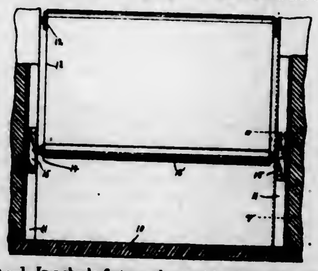


3. In a curtain-fixture, the combination with the curtain, of tapes secured to the curtain, a rotatable drum for taking up said tapes, a spring for rotating the drum, and means for frictionally resisting the rotation of the drum when the said drum is rotated in the direction to let off the tapes, substantially as and for the purpose described.

4. In a curtain-fixture, the combination of a window-frame, a spring-actuated roller mounted therein, a curtain winding upon the roller, a spring-rotated drum mounted upon the window-frame, a pair of tapes each having an end secured to the curtain, the other ends of the tapes being brought to the drum and winding thereon from opposite sides of said drum, for the purpose described.

5. In a curtain-fixture, the combination of a window-frame, a spring-actuated roller mounted therein, a curtain winding upon said roller, a curtain-stick for said roller, a spring-rotated drum mounted upon the upper portion of said window-frame, a pair of pulleys mounted on the lower portion of said window-frame, a pair of tapes each passing around one of said pulleys and having one end secured to one end of said curtain-stick, the other ends of the tapes being brought to the drum and winding thereon from opposite sides of said drum, substantially as described.

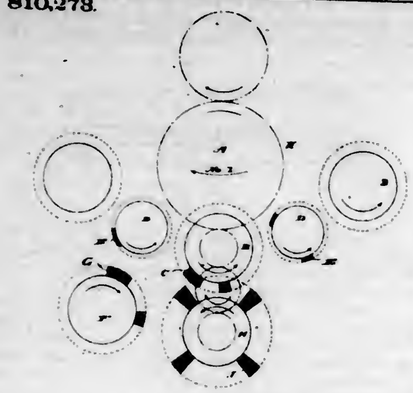
810,279. SHADE-FIXTURE. CHARLES L. HOPKINS, Albany, N. Y., assignor to The Curtain Supply Company, Newark, N. J., a Corporation of New Jersey. Filed Sept. 20, 1903. Serial No. 173,091.



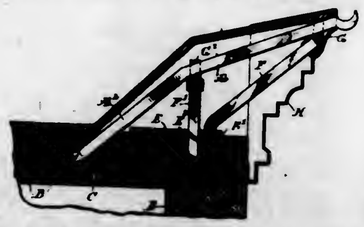
Claim.—1. In a shade-fixture, the combination with a spring-actuated shade, of a stick carried by the shade, shoes at the ends of the stick, a groove adjacent to the shade forming a guideway for the shoe, a yielding surface within the groove with which the shoe normally contacts, and a harder surface adjacent to the yielding surface with which the shoe may contact when the shade-fixture is tilted, for the purpose set forth.

2. In a shade-fixture, the combination with a shade, of a stick carried by the shade, an elongated, spring-pressed shoe at the end of the stick having a plurality of contact-points, a side post adjacent to the shade having a plurality of friction-surfaces of unlike frictional holding power, one of the contact-points of the shoe normally engaging a friction-surface having greater frictional holding power and one or more contact-points adapted to engage a friction-

810,273.



810,274. SUPPORT FOR HOISTING DEVICES. LOUIS GREENBEY, New York, N. Y. Filed Oct. 14, 1905. Serial No. 282,708.



Claim.—1. A hoist-supporting device for buildings, comprising a hook-bar, and means for permanently securing the hook-bar to the building at the roof thereof, the hook of the said hook-bar projecting through the cornice of the building.

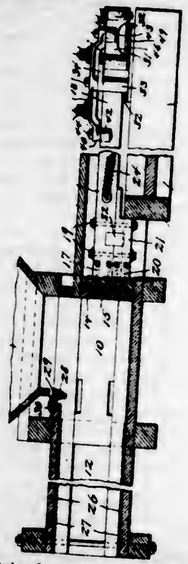
2. A hoist-supporting device for buildings, comprising a hook-bar having its outer end terminating in a hook and having its inner end forked and secured to roof-beams, the hook projecting beyond the face of the cornice of the building, a roof-beam chair and braces seated in the sockets formed therein.

3. A hoist-supporting device for buildings, comprising a hook-bar having its outer end terminating in a hook and having its inner end forked and secured to roof-beams, the hook projecting beyond the face of the cornice of the building, a roof-beam chair and braces seated in the sockets formed therein, each brace having a shoe for the hook-bar to rest on.

810,275. HAY-PRESS. THOMAS R. HACKWORTH, South Pittsburg, Tenn. Filed Feb. 24, 1905. Serial No. 247,169.

Claim.—1. In a device of the class described, a press-box having a baling-box extending from one end and a supporting base-frame extending from the other end, a plunger for reciprocation in said press-box and having an operating-beam extending therefrom, a spring connected to yieldably maintain said beam and plunger in withdrawn position, a stud extending from said base-frame in central alinement with said press-box, a trip-arm pivoted at one end to said base-frame with the body of trip-arm in alinement with the body of the beam and with a transverse recess near its free end, means for connecting the free end of said beam to the free end of said trip-arm and in central alinement therewith, and a crank-arm mounted for rotation and provided with a roller at the free end for engaging the body of said trip-arm centrally and passing through said recess at the terminal of the forward stroke to release the trip-arm.

2. The combination in a device of the class described, of a press-box having a spring-controlled plunger and operating-beam mounted for reciprocation, and with a base-frame extending rearwardly therefrom, a trip-arm pivoted by one end and movably connected by the free end of said beam and provided with a transverse recess near said free end, a crank-arm having depending ends terminating in semi-globular hubs, rollers having semispherical cavities engaging said hubs and maintained rotatively thereon by binding-bolts, said rollers engaging said trip-arm and passing through said recess at the end of the stroke, whereby the lateral strains are borne by the hubs and the pivot-pins relieved from lateral strains

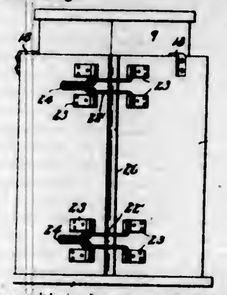


3. In a device of the class described, a press-box having a baling-box extending from one end and a supporting base-frame extending from the other end and provided with a transverse stop, a plunger mounted for reciprocation in said press-box, a beam extending rearwardly of said plunger and provided with a transverse recess, a stop member rigidly secured to said beam and bearing against said base-stop when the plunger is in withdrawn position and provided with a transverse recess for registration with the recess in said beam, a transverse chock for fitting in said recesses, a spring for holding said beam and its attached stop member yieldably in withdrawn position, and tripping means for moving said beam and its attached plunger and stop member in one direction and releasing the same for the return movement by the action of said spring.

4. In a device of the class described, a press-box having a baling-box extending from one end and a supporting base-frame extending from the other end and provided with a transverse stop, a plunger for reciprocation in said press-box and having an operating-beam extending therefrom provided with a transverse recess, a stop member rigidly secured to said beam for bearing against said base-stop when the beam is in withdrawn position and provided with a transverse recess for registration with the recess in said beam, a transverse chock fitting in said recess, a spring connected to yieldably maintain said beam and plunger in withdrawn position, a stud extending from said base-frame in central alinement with said press-box, a trip-arm pivoted by one end to said stud with the body of the trip-arm opposite the body of the beam and with a transverse recess near its free end, straps attached to opposite sides of the free end of said beam and pivoted to the opposite sides of the free end of said trip-arm, and a crank-arm mounted for rotation and provided with a roller at its free end for engaging said trip-arm and passing through said recess at the terminal of the forward stroke to release the trip-arm.

810,276. MOLD FOR DRAIN OR SEWER PIPES. JAMES B. HILL, Findlay, Ohio. Filed Aug. 30, 1905. Serial No. 276,426.

Claim.—1. A mold comprising a base provided with an upwardly-extending flange, a sectional inner shell engaging the adjacent walls of the flange, a sectional expanding ring resting on the base and serving to clamp the inner shell in engagement with said walls, an expansible outer shell of less height than the inner shell and spaced from the latter to favor an intermediate molding-chamber, inwardly-extending lugs secured to the upper end of the outer shell and adapted to engage the exterior walls of the inner shell, loops pivotally mounted on one longitudinal edge of the outer shell, and hooks pivotally mounted on the adjacent longitudinal edge of the shell and adapted to engage said loops for clamping the outer shell in engagement with the flange.



2. A mold comprising a base provided with an upwardly-extending flange, a sectional inner shell engaging said flange, a flat sectional expanding ring engaging the interior walls of the inner shell and provided with alined inwardly-extending operating-handles, a retaining-collar provided with a seating-groove for the reception of the upper end of the inner shell, a split expansible outer shell spaced from the inner shell, to form an intermediate molding-chamber and having one longitudinal edge thereof formed with a vertical groove adapted to receive the adjacent longitudinal edge of the outer shell, and means for clamping the outer shell in engagement with the flange.

810,277. ATTACHMENT FOR CHAIRS. VIRGINIA M. HOLLYDAY, Baltimore, Md. Filed Apr. 4, 1905. Serial No. 253,703.

Claim.—1. A double seat of the vis-à-vis type having a central support between the seats proper, the same being provided with two passages serving as hearing and speaking tubes and having open mouths which project rearward on opposite sides of the central support so that each set of such mouths is available for hearing and speaking by the person occupying the contiguous seat, substantially as described.

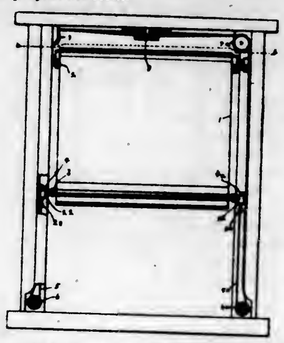
2. An improved article of furniture, comprising a double seat having backs and an intervening or middle portion forming a continuation thereof, and a horizontal bar C forming a rigid attachment of such middle portion, and provided with passages opening on opposite sides of the bar and arranged for convenience of use for hearing and speaking in the manner described.

3. A seat comprising two seats proper and a rigid vertical frame intervening the same and having at the top lateral projections each provided with a passage opening at one end on the rear side thereof or toward the back of the contiguous seat, the opposite end of the passage opening on the other side of the frame, as and for the purpose specified.

810,278. CURTAIN-FIXTURE. CHARLES L. HOPKINS, Albany, N. Y., assignor to The Curtain Supply Company, Newark, N. J., a Corporation of New Jersey. Filed Aug. 21, 1903. Serial No. 170,373.

Claim.—1. In a curtain-fixture, the combination of a window-frame, a roller mounted therein, a spring for rotating the roller, a curtain winding upon said roller, a winding-drum mounted upon the window-frame, a spring for rotating the winding-drum, a tape, winding upon said winding-drum, the end of the tape, being secured to the curtain, the power of the springs being opposed the one to the other whereby the curtain and tape are maintained in a tense condition, substantially as described.

2. In a curtain-fixture, the combination with a curtain, of flexible connections secured to the lower edge of the curtain, a rotatable drum upon which the flexible connections wind, means for impeding the rotation of the drum in one direction, the said drum having free rotation in the opposite direction, and spring means for rotating the drum, for the purpose set forth.

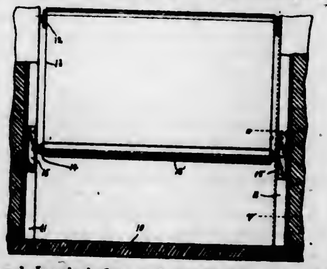


3. In a curtain-fixture, the combination with the curtain, of tapes secured to the curtain, a rotatable drum for taking up said tapes, a spring for rotating the drum, and means for frictionally resisting the rotation of the drum when the said drum is rotated in the direction to let off the tapes, substantially as and for the purpose described.

4. In a curtain-fixture, the combination of a window-frame, a spring-actuated roller mounted therein, a curtain winding upon the roller, a spring-rotated drum mounted upon the window-frame, a pair of tapes each having an end secured to the curtain, the other ends of the tapes being brought to the drum and winding thereon from opposite sides of said drum, for the purpose described.

5. In a curtain-fixture, the combination of a window-frame, a spring-actuated roller mounted therein, a curtain winding upon said roller, a curtain-stick for said roller, a spring-rotated drum mounted upon the upper portion of said window-frame, a pair of pulleys mounted on the lower portion of said window-frame, a pair of tapes each passing around one of said pulleys and having one end secured to one end of said curtain-stick, the other ends of the tapes being brought to the drum and winding thereon from opposite sides of said drum, substantially as described.

810,279. SHADE-FIXTURE. CHARLES L. HOPKINS, Albany, N. Y., assignor to The Curtain Supply Company, Newark, N. J., a Corporation of New Jersey. Filed Sept. 29, 1903. Serial No. 176,081.



Claim.—1. In a shade-fixture, the combination with a spring-actuated shade, of a stick carried by the shade, shoes at the ends of the stick, a groove adjacent to the shade forming a guideway for the shoe, a yielding surface within the groove with which the shoe normally contacts, and a harder surface adjacent to the yielding surface with which the shoe may contact when the shade-fixture is tilted, for the purpose set forth.

2. In a shade-fixture, the combination with a shade, of a stick carried by the shade, an elongated, spring-pressed shoe at the end of the stick having a plurality of contact-points, a side post adjacent to the shade having a plurality of friction-surfaces of unlike frictional holding power, one of the contact-points of the shoe normally engaging a friction-surface having greater frictional holding power and one or more contact-points adapted to engage a friction-

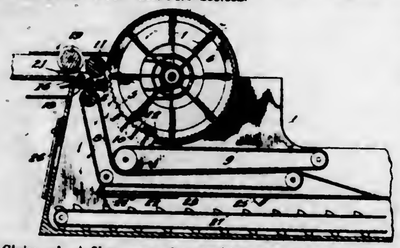
surface having less frictional holding power when the shade-fixture is tilted, for the purpose set forth.

3. In a shade-fixture, the combination with the shade, of a stick carried by the shade, a shoe carried by the stick, a window-frame adjacent to the shoe, a frictional holding-surface upon the window-frame with which the shoe normally engages, and another surface upon the window-frame having less holding power upon the shoe than the first-named holding-surface and with which the shoe may engage when the shade-fixture is inclined.

4. In a shade-fixture, the combination with the shade and a stick carried thereby, of a shoe at the end of the stick, a plurality of opposing surfaces adjacent to the shoe with which the shoe may engage, said surfaces having unequal holding power upon the head, and said shoe, when in contact with either of said surfaces, being movable in both directions over the latter for the purpose set forth.

5. In a shade-fixture, the combination with the shade and a stick carried thereby, of shoes at the ends of the stick, a plurality of opposing surfaces adjacent to a shoe having unlike holding power, the shoe normally contacting only with an opposing surface having greater holding power but contacting with an opposing surface having less holding power when the fixture is tilted, for the purpose set forth.

810,280. FIBER-SCUTCHER. EDMUND B. HORINE, Nicholasville, Ky., assignor of one-half to Roscoe Horine Welch, Lexington, Ky. Filed June 13, 1905. Serial No. 265,102.



Claim.—1. A fiber-separating machine comprising a stationary casing having an inlet-opening, and an outlet-opening below the inlet-opening, a rapidly-revolving fan mounted in said casing, scutcher-plates mounted concentrically on said fan and having teeth in their outer edges, and a conveyer passing in close proximity to said outlet-opening for receiving the fiber therefrom, such conveyer being so constructed as to permit the chaff and other refuse being forced therethrough by the blast from the fan.

2. A fiber-separating machine comprising a stationary casing having an inlet-opening, and an outlet-opening below the inlet-opening, a rapidly-revolving fan mounted in said casing, scutcher-plates mounted concentrically on said fan and having teeth in their outer edges, said plates being arranged in zigzag form, with the apexes of the angular portions thereof intersecting a common plane perpendicular to the axis of rotation, and a conveyer moving in close proximity to said outlet opening.

3. A fiber-separating machine comprising a casing having an inlet-opening, a fixed bar forming the bottom of such opening, a series of feed-rollers adjacent to said bar, a pressure-roller for holding and crushing the stalks against said series of rollers, said casing having an outlet-opening beneath said bar, a rapidly-rotating fan mounted in said casing, a series of scutcher-plates arranged concentrically on said fan and having teeth in their outer edges, and a conveyer in close proximity to said outlet-opening.

4. A fiber-separating machine comprising a stationary casing having an inlet-opening, and an outlet-opening beneath said inlet-opening, a rapidly-revolving fan within said casing, scutcher-plates mounted on said fan, and means for preventing the fiber from being drawn inwardly through said outlet-opening by the suction or reaction of the fan.

5. A fiber-separating machine comprising a stationary casing having an inlet-opening, and an outlet-opening beneath said inlet-opening, a rapidly-revolving fan within said casing, scutcher-plates mounted on said fan, and a series of deflectors mounted on said casing beneath said outlet-opening for preventing the fiber from being drawn through said outlet-opening by the suction or reaction of the fan.

6. A fiber-separating machine comprising a stationary casing having an inlet-opening, and an outlet-opening beneath said inlet-opening, a rapidly-revolving fan within said casing, scutcher-plates mounted on said fan, and a series of doors for increasing the area of said outlet-opening, said doors when opened being at substantially right angles to said casing and acting as deflectors for preventing the fiber from being drawn inwardly through said outlet-opening by the suction or reaction of the fan.

7. A fiber-separating machine comprising a circular casing having an inlet-opening, a fixed bar forming the bottom of such inlet-opening, an outlet-opening beneath such bar, means for increasing the area of such outlet-opening, a conveyer movable in close proximity to such outlet-opening, a rapidly-revolving fan mounted in said casing, a series of scutcher-plates mounted at the periphery of such fan and encircling the latter, such plates being arranged in zigzag form and having teeth in their outer edges, a series of feed-rollers adjacent said fixed bar, and a pressure-roller mounted above said feed-rollers.

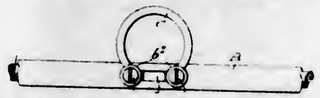
8. A fiber-separating machine having a feed-table, a rotary scutcher, means for holding the stalks while they are being acted upon by the scutcher, a roller mounted above the feed-table and means coöperating with such roller for equally distributing the stalks to said holding means.

9. A fiber-separating machine having a feed-table, a rotary scutcher, means for holding the stalks while they are being acted upon by the scutcher, and a roller mounted above said table having a right and left hand spiral extending from its center to each end.

10. A fiber-separating machine having a feed-table, a rotary scutcher, means for holding the stalks while they are being acted upon by the scutcher, a roller mounted above said table having a right and left hand spiral extending from its center to each end, and guide-plates extending upwardly from the bottom of the feed-table beneath said roller.

11. In a fiber-separating machine, a casing having an inlet-opening, feed-rollers, an upper roller for holding and crushing the stalks against said rollers, scutcher-plates rotating in the direction of their lengths, a fan, and conveyers traveling at a higher speed than the feed-rollers for exerting a pull on the fiber.

810,281. CURTAIN-FIXTURE. PAUL A. HOUGHTALING, Riverton, N. J., assignor to The Curtain Supply Company, Newark, N. J., a Corporation of New Jersey. Filed Jan. 9, 1905. Serial No. 240,212.



Claim.—1. In a curtain-controlling device, the combination of two shoe-rods connected to the lower portion of the curtain, and a substantially U-shaped spring joining said rods and tending to force them apart, substantially as described.

2. In a curtain-controlling device, the combination of a tubular curtain-rod, two shoe-rods within said curtain-rod, and a spring outside of the curtain-rod operatively associated with the ends of said shoe-rods, and tending to force them apart, substantially as described.

3. In a curtain-controlling device, the combination of a tubular curtain-rod, two shoe-rods within said curtain-rod, and a substantially U-shaped spring having its ends attached respectively to the said shoe-rods and tending to force them apart, substantially as described.

4. The combination of a pair of shoe-rods guided in the lower portion of a curtain, a substantially U-shaped spring connecting said rods and tending to force them apart, with pinch-handles for moving said rods toward each other against the action of the spring, substantially as described.

5. The combination of a tubular curtain-rod supported on the lower portion of a curtain, two shoe-rods, a substantially U-shaped spring operatively associated with said shoe-rods through a slot in the curtain-rod, and pinch-handles connected to said spring for moving together the shoe-rods, substantially as described.

6. The combination of a tubular curtain-rod, shoe-rods within the same, handles operatively associated with the shoe-rods and projecting through a slot in the curtain-rod, with a piece of spring material extending between said handles outside of said curtain-rod, substantially as described

7. The combination of a tubular curtain-rod, two shoe-rods therein, with a piece of spring material operatively associated with the ends of the shoe-rods and projecting above the same, with handles connected to the spring-piece, substantially as described.

8. A curtain-fixture including a pair of oppositely-disposed rods, pinch-handles operatively associated with said rods, and a spring bridging said handles for normally shifting the rods in opposite directions, said pinch-handles and spring being formed for joint attachment to said rods.

9. A curtain-fixture including a pair of oppositely-disposed rods, pinch-handles operatively associated with said rods, and a spring bridging said pinch-handles for normally shifting one of said rods in one direction, said pinch-handles and spring being formed for joint attachment to said rods.

10. A curtain-fixture including a pair of oppositely-arranged rods, and a bow spring bridging the space between said rods for relatively shifting said rods, in combination with means for fastening the ends of said spring to the ends of said rods.

11. A curtain-fixture including a pair of oppositely-arranged rods, and a bow spring bridging the space between said rods for relatively shifting one of said rods, in combination with means for fastening the ends of said spring to the ends of said rods.

12. A curtain-fixture including a pair of oppositely-arranged rods, a spring bridging said rods and connected thereto for relatively shifting said rods, and pinch-handles connected to and projecting outwardly from said spring, said pinch-handles and spring being formed for joint attachment to said rods.

13. A curtain-fixture including a pair of oppositely-arranged rods, a spring bridging said rods and connected thereto for relatively shifting one of said rods, and a pinch-handle projecting outwardly from said spring, said pinch-handle and spring being formed for joint attachment to said rods.

14. A curtain-fixture including a pair of oppositely-arranged rods and a bow spring operatively associated with the rods for relatively shifting one of them.

15. A curtain-fixture including a curtain-stick, a pair of oppositely-arranged rods therein, and a spring for relatively shifting one of said rods connected thereto at its inner end, said spring being arranged without the curtain-stick.

16. A curtain-fixture including oppositely-arranged rods, means for relatively shifting one of said rods comprising a spring having apertured portions, and screws passing through said apertured portions and engaging the rods to secure the springs in place.

17. A curtain-fixture including oppositely-arranged rods, means for relatively shifting one of said rods comprising a bow spring having apertured portions, and screws passing through said apertured portions and engaging the rods to secure the spring in place.

18. A curtain-fixture including oppositely-arranged rods, means for relatively shifting one of said rods comprising a spring having apertured portions, screws passing through said apertured portions and engaging the rods to secure the spring in place, and a pinch-handle projecting from said spring.

19. A curtain-fixture including oppositely-arranged rods, means for relatively shifting one of said rods comprising a bow spring having apertured portions, screws passing through said apertured portions and engaging the rods to secure the spring in place, and a pinch-handle projecting from said spring.

20. In a curtain-fixture, a holding part formed to engage the guideway of a window-frame, a bow spring for actuating the same, and a pinch-handle joined with said spring formed to project without said guideway.

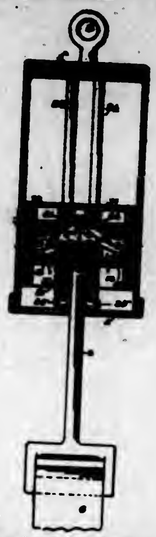
21. In a curtain-fixture, a holding part formed to engage the guideway of a window-frame, a bow spring for actuating the same, and a pinch-handle integral with said spring formed to project without said guideway.

810,282. RECOIL-CHECK FOR VEHICLES. HENRY A. HOUSE, Bridgeport, Conn. Filed Apr. 20, 1905. Serial No. 256,621.

Claim.—1. A recoil-check adapted to arrest the sudden return of a vehicle-spring after compression comprising a casing expansible grippers adapted to have both a lateral and a longitudinal movement, within said casing, means for expanding said grippers under a sudden strain so as to temporarily check the recoil of the vehicle-spring, means to permit the moderate recovery of said spring, for the purpose set forth.

2. A recoil-check adapted to arrest the sudden return of a vehicle-spring after compression, comprising a casing, grippers adapted to have both a lateral and a longitudinal movement in said casing, means for expanding said grippers under a sudden strain so as to temporarily check the recoil of the vehicle-spring, means to permit the moderate recovery of said spring, for the purpose set forth.

3. A recoil-check adapted to arrest the sudden return of a vehicle-spring after compression comprising a casing, grippers adapted to frictionally engage the inner wall of said casing, toggle-arms on said grippers, a connecting-rod extending said arms to effect said frictional engagement, recovering-springs acting against said grippers, and adapted thereby to permit of a gradual recovery of the vehicle-spring, for the purpose set forth.



4. The combination, in a vehicle having compressible springs, of a recoil-check adapted to arrest the sudden recoil of said springs after compression, said recoil-check connected with the vertically-movable body portion of the vehicle and the axle or other like non-vertical movable part of the vehicle, said check comprising a casing, grippers located within said casing and adapted to have both a lateral and longitudinal movement therein, toggle-arms on said grippers, a connecting-rod adapted to actuate said grippers through the medium of said grippers and against the interior wall of the casing under the compression of the vehicle-springs and thus temporarily prevent the sudden recoil of said springs, recoil-springs within the casing to relieve the outward pressure of said grippers and permit the gradual recovery of the vehicle-springs, for the purpose set forth.

5. The combination, with a vehicle having compressible springs, of a recoil-check connected with the vertically-movable body portion of the vehicle and the axle or other like non-vertical movable part of the vehicle, one of said connections being flexible, said recoil-check comprising a casing, grippers within said casing and adapted to have both a lateral and a longitudinal movement therein and always in frictional contact with the interior wall of the casing toggle-arms pivotally supported on said grippers, a connecting-rod adapted to actuate said grippers against the interior wall of the casing under the compression of the vehicle-springs and thus temporarily check the sudden recoil of said springs, means to partially release the frictional contact of said grippers and permit the gradual recovery of the vehicle-springs, for the purpose set forth.

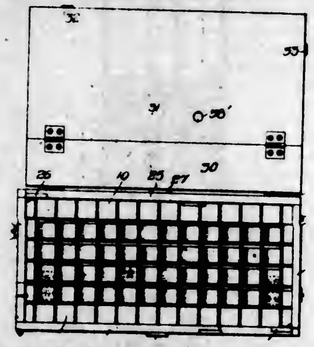
6. The combination, in a vehicle having compressible springs, of a recoil-check comprising a casing, a connecting-rod longitudinally movable therein, means for connecting the casing and connecting-rod to the vehicle, one to a vertically-movable part, and the other to a non-vertical movable part, grippers adapted to have both a lateral and longitudinal movement in the casing, toggle-arms having one of their ends pivotally supported to said grippers, their free ends operatively connected to said connecting-rod so that, when the vehicle-springs are compressed, said grippers are expanded forcibly against the casing to temporarily check the recoil of said springs, means for partially releasing the contact of said grippers to permit of their gradual recovery, for the purpose set forth.

7. The herein-described recoil-check comprising a casing, expansible grippers therein, toggle-arms having one of their ends pivotally supported on said grippers, a connecting-rod, the free ends of the grippers connected with said rods, studs secured to said casing and passing freely through said grippers, springs embracing said studs having a kicking-post both on the studs and grippers, for the purpose set forth.

8. The herein-described recoil-check comprising a dust-proof

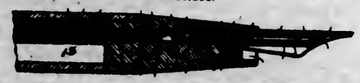
casing, expansible grippers therein, toggle-arms having one of their ends pivotally supported on said grippers, a connecting-rod, the free ends of the grippers connected with said rods, studs secured to said casing and passing freely through said grippers, springs embracing said studs having a kicking-post both on the studs and grippers, for the purpose set forth.

810,283. FOLDING EGG-CRATE. ANDREW D. IRBIE, Forney, S. D. Filed May 6, 1904. Serial No. 206,602.



Claim.—A collapsible crate comprising a bottom including major and minor hinged members, a side hinged to said minor member of said bottom, ends each comprising a major and a minor member hinged together, the major member of one end being hinged to the said side at one of its ends and the minor member of the other end being hinged to the said side at the other of its ends, a second side hinged to the major member of the first-named end, a lid comprising a minor section hinged to the last-named side and a major member hinged to the minor section, the said major member of the bottom being adapted to lie with one of its faces against one of the faces of one of the major portions of one of the ends and a portion of one of the faces of one of the sides.

810,284. FOUNTAIN-PEN. FRANK M. KNEISS, Philadelphia, Pa. Filed Mar. 20, 1905. Serial No. 251,196.



Claim.—1. A fountain-pen feeder of uniform depth from end to end and having its forward portion reduced in width to form a narrow tongue with parallel flat sides which extend substantially at right angles to the nib of the pen, said feeder having top and bottom grooves and fissures located in said grooves, said fissures and grooves all terminating at their inner ends in an enlarged interrupting space.

2. A fountain-pen feeder comprising a body portion and a tongue extending forward therefrom and, together with the body portion, being grooved to conduct the ink to the pen-nib, the tongue being provided near its outer end with air-holes extending through the sides of the tongue adjacent to the upper edge thereof.

3. A fountain-pen feeder having its body formed with a top groove in its forward portion and a bottom groove in its rear portion, each of said grooves being provided with auxiliary capillary fissures, and an enlarged interrupting space being left at the junction of said top and bottom grooves.

4. A fountain-pen feeder formed with a top groove in its forward portion and a bottom groove in its rear portion, said grooves terminating at their inner ends in an interrupting space formed by the junction of the grooves, both grooves being provided with capillary fissures which also terminate and lead into said space.

5. A fountain-pen feeder having a groove formed in its upper side under the pen-nib and provided with a drain formed in the upper edge of the feeder and leading from the outside of the feeder inward to the groove and located within the mouth of the pen.

810,285. PIANO-REPAIRER'S TOOL. SAMUEL H. KING, Marion, Ind., assignor of one-third to David A. Williams, Marion, Ind. Filed Oct. 6, 1905. Serial No. 281,669.

Claim.—1. A tool, substantially as herein described, comprising a guide-rod socketed in its outer end to engage with the end of a tune-pin and provided with a disk or piston and with a shank projecting therefrom, a pusher-cylinder having at its outer end an opening for the guide-rod and threaded within its opposite end, the stock threaded in said end of the cylinder and having a socket to receive the shank of the guide-rod, an extension, having a knob against which the operator may press, and a spring within the cylinder and bearing between the disk or piston and the stock, all substantially as and for the purpose set forth.

2. A tool for use in polishing piano tune-pins, comprising means for engaging against the end of a pin, and means movable thereover for shifting the polishing medium along the pin to be polished.

3. A tool for use in polishing piano tune-pins, comprising a rod to bear against the end of the pin to be polished, and a cylindrical pusher movable along and over the said rod whereby it may operate to push or shift the polishing medium along the pin to be polished.

4. A tool for use in polishing piano tune-pins, comprising a guide-rod to bear against the end of a pin, a cylindrical pusher movable over said rod and adapted to be shifted at one end along the pin to be polished, and a spring bearing between said rod and cylinder.

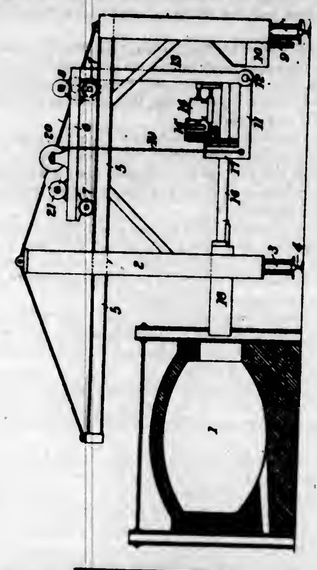
5. A tool for use in polishing piano tune-pins, comprising a guide-rod to bear against the outer end of a tune-pin, a cylinder over said guide-rod and movable along and beyond the outer end thereof, a spring for actuating the guide-rod, and a rod in connection with the cylinder and having a knob against which the operator may press in the use of the invention, substantially as set forth.

810,286. FURNACE-CHARGING APPARATUS. WILLIAM G. KRAMS, Sharon, Pa., assignor to The National Malleable Castings Company, Cleveland, Ohio, a Corporation of Ohio. Filed June 30, 1905. Serial No. 267,736.

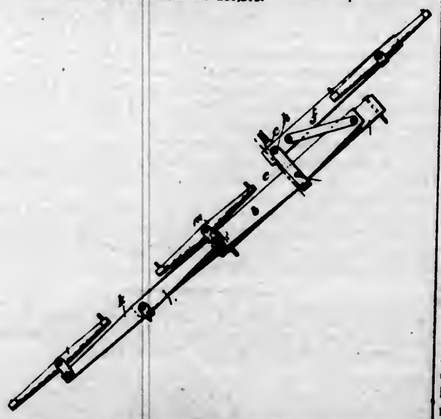
Claim.—1. Furnace-charging apparatus comprising a traveling carriage or crane, a trolley thereon, a frame pivoted at the rear to a support depending from the trolley, a rotary charging-bar on the frame, and a flexible connection extending from the trolley and adapted to raise and lower the frame on its pivot; substantially as described.

2. Furnace-charging apparatus comprising a traveling carriage or crane, a trolley thereon, a frame pivoted at the rear to a support depending from the trolley, a motor on the frame, a rotary charging-bar on the frame, and a flexible connection extending from the trolley and adapted to raise and lower the frame on its pivot; substantially as described.

810,286.

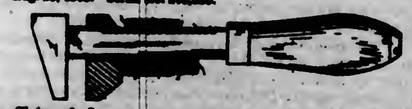


810,287. HORSE-HYDNER. JOHN B. LALLY, Frankfort, Kans. Filed June 28, 1905. Serial No. 267,370.



Claim.—In a three-horse evener of the character described, the combination of the base-bar, the lead-bar and its equipments secured on the base-bar, the draft-hook and its shank, the latter extending between said bars, the equalizer-bar supported on the shank of the draft-hook, the binding-clevis, a bolt securing the base-bar and lead-bar and shank of the draft-hook together and a bolt connecting the inner end of the equalizer-bar and shank of the draft-hook.

810,288. WRENCH. MARTIN M. LE MAY, Leighton, Ala. Filed Aug. 16, 1905. Serial No. 274,288.



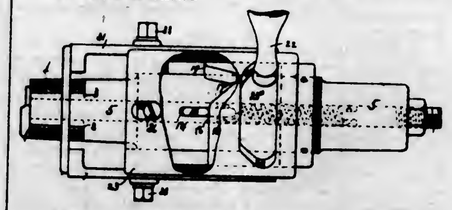
Claim.—1. In a wrench, a rigid jaw having a shank with rib projections on one edge, a slidable jaw having a tubular shank embracing the shank of the rigid jaw and formed with a slot to expose the rib projections of the latter, a boss on the shank of the slidable jaw, and an internally-threaded sleeve rotatably disposed on the shank of the slidable jaw between the latter and the said sleeve and having reversely- inclined faces at opposite ends and an unthreaded portion extending longitudinally therethrough to clear the rib projections of the shank on the rigid jaw.

2. In a wrench, a rigid jaw having a shank with rib projections on one edge, a slidable jaw having a shank embracing the shank of the rigid jaw and provided with a projection near its rear terminal, and an internally-threaded sleeve rotatably disposed on the shank of the slidable jaw and provided with reversely-inclined faces at opposite ends to jam the same between the slidable jaw and the projection to lock the said latter jaw in adjusted position.

3. In a wrench, a rigid jaw having a shank provided with rib projections, a slidable jaw having a shank embracing the shank of the rigid jaw and provided with a projection at a distance from the jaw thereof, and a sleeve rotatably disposed on and movable with the shank of the slidable jaw, the said sleeve having internal threads partially extending thereover, and reversely-inclined faces at opposite ends beginning and terminating at inner and outer portions of shoulders.

4. In a wrench, a rigid jaw having a shank with rib projections on one edge, a slidable jaw having a tubular shank to embrace the shank of the rigid jaw, said tubular shank being longitudinally slotted to expose the rib projections, and also provided with a boss at the rear extremity diametrically opposite the slot, and a sleeve having threads extending around a portion of the interior thereof, and the remaining part of the interior unthreaded, said sleeve being rotatably disposed on the shank of the slidable jaw and having reversely-inclined faces at the forward and rear ends to respectively engage the adjacent edge portions of the slidable jaw and the projection.

810,289. COLLAPSIBLE TAP. WILBUR A. LEONARD, New Haven, Conn., assignor, by mesne assignments, to The Geometric Tool Company, New Haven, Conn., a Corporation of Connecticut. Filed Jan. 26, 1905. Serial No. 243,104.



Claim.—1. A collapsible screw-thread-cutting implement, comprising a slotted stock, cutters in the slots, and a plunger longitudinally movable in the stock, with radial webs on the plunger projecting into the cutter-slots with wedge-surfaces to act on the cutters.

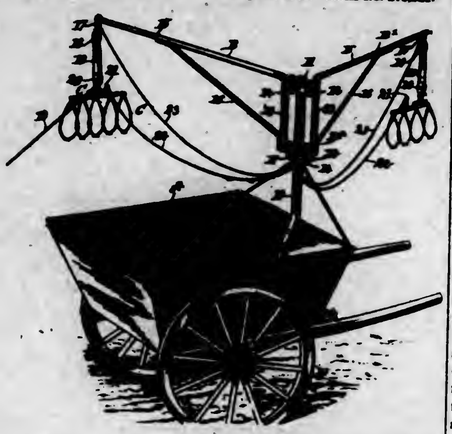
2. A collapsible screw-thread-cutting implement, comprising a slotted stock, cutters in the slots, a plunger longitudinally movable in the stock, wedge-surfaces between the plunger and cutters adapted to positively move the cutters upon the movement of the plunger, in combination with a pin in the plunger, a cam for said pin, an abutment-sleeve adapted for longitudinal movement on the stock, and means for operating the cam by the movement of said abutment-sleeve.

3. A collapsible screw-thread-cutting implement, comprising a slotted stock, cutters in the slots, a plunger longitudinally movable in the stock, wedge-surfaces between the plunger and cutters adapted to positively move the cutters upon the movement of the plunger, in combination with a cross-pin on the plunger, a cam-collar rotatable on the stock having oppositely-inclined cam-faces of different heights and means for causing either of said faces to move the plunger-pin.

4. A collapsible screw-thread-cutting implement, comprising a slotted stock, cutters in the slots, a plunger longitudinally movable in the stock, wedge-surfaces between the plunger and cutters adapted to positively move the cutters upon the movement of the plunger, in combination with a cross-pin on the plunger, a cam-collar rotatable on the stock and engaged by said cross-pin, a bank-stop for the collar, an operating-stud for the cam, an abutment-sleeve longitudinally movable on the stock, and means for preventing its rotation thereon, a cam-groove in the casing through which the cam-stud projects and a return-spring for the plunger.

5. In combination, a stock having radial slots for the cutters and a plunger having radial webs projecting into said radial slots to there engage said cutters to move them inwardly, and outwardly by longitudinal movement of the plunger.

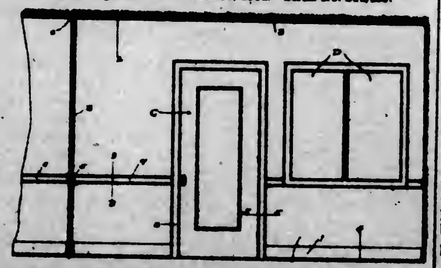
810,290. DEVICE FOR LOADING SUGAR-CANE. GUSTAVE D. LUSH, New Orleans, La. Filed Aug. 22, 1905. Serial No. 275,321.



Claim.—1. A standard adapted for attachment to a vehicle, cranes removably mounted on said standard at opposite sides thereof and arranged to swing to and from each other, grapples, block-and-fall connections between the grapples and the cranes, independent shifting-cables for the cranes, and independent tripping-cables for the grapples.

2. A standard adapted for attachment to a vehicle-body, having cross-arms secured thereto, which arms terminate in knuckles at their outer ends, cranes adapted for removable and swinging connection with the standard, each crane comprising a vertical swing member and a carrying member at an angle to the swing member and having an upward and outward inclination, and pintles extending down from a side of the swing member, adapted to enter the knuckles on the cross-arms of the standard, a block connected with the outer end of the swing-arm of each crane, a grapple located beneath each of said blocks and provided with a trip-arm, a block connected with each grapple, an operating-rope connected with the blocks of the grapples and the blocks carried by the swing-arms of the cranes, a rope connected with the outer end of the swing-arm of each crane, and a second rope connected with the trip-arm of each grapple, all of said ropes being connected at their inner ends with the said standard.

810,291. INTERIOR BUILDING CONSTRUCTION. WILLIAM D. MANN, Chicago, Ill. Filed June 27, 1904. Serial No. 214,499.



Claim.—1. The method of erecting and securing in position the interior walls of a building, which consists in first preparing the trim, then placing parts of the trim in position then erecting the wall exclusive of its plaster, then securing other parts of the trim in place, and then finishing the wall, substantially as described.

2. The method of erecting and securing in position the interior walls of a building, which consists in placing parts of the trim in position, then erecting the wall-frame, then placing other parts of the trim in position, and then plastering to the trim, substantially as described.

3. The method of building interior walls, which consists in first preparing a base-piece, chair and picture rails, then setting the base-piece and picture-rail in position, then erecting the wall-frame, then setting the chair-rails in position, and then plastering the wall-frame, substantially as described.

4. The method of building interior walls, which consists in first preparing a base-piece, a door-jamb, picture and chair rails, setting the base-piece and door-jamb in position, erecting the wall-frame, setting the railings in position, and then plastering the wall-frame, substantially as described.

5. The method of building interior walls, which consists in first preparing the trim, then setting certain parts of the trim in position on the floor, then erecting the wall-frame, then setting the other parts of the trim by securing them to the wall-frame, and finally finishing the wall-frame, substantially as described.

6. The step in the method of erecting and securing in position the interior walls of a building, which consists in placing parts of the trim in position on the wall-frame, and then plastering to the trim, substantially as described.

7. In interior building construction, a trim extending from the wall construction beyond the finish of the wall, whereby the trim can be first secured in position and then the wall finished, substantially as described.

8. In interior building construction, a trim consisting of a socket member adapted to receive the wall structure and to extend out beyond the same, in combination with a portion of the permanent wall structure fitting into said socket whereby the trim can be first set and then the wall structure built and finished, substantially as described.

9. The method of erecting interior walls, which consists in placing a socketed base-piece, a socketed picture-mold cap, and a socketed door-jamb in position, then building the wall-frame, and then plastering the same.

10. The method of erecting interior walls, which consists in placing a socketed base-piece, a socketed picture-mold cap and a socketed door-frame in position, then building the wall, then securing a chair-rail to the wall-frame, and then plastering such frame.

11. A trim for building constructions, consisting of a sheet-metal strip formed into the shape of the trim for opposite sides of the same wall, and filled with cement made in socket form to receive the wall structure, substantially as described.

12. The combination with an interior building-wall, of trim therefor, extending from the wall-frame through the finish, substantially as described.

13. The combination with an interior building-wall, of a trim therefor comprising a socket member adapted to receive the frame construction of the wall and to serve as trim for the opposite side of the wall, substantially as described.

810,292. SPOOL-HOLDER. JOHN W. MEAKER, Chicago, Ill., assignor, by mesne assignments, to Meaker Sales Company, a Corporation of Michigan. Filed Apr. 30, 1904. Serial No. 206,696.

Claim.—1. A spool-holder of the character described, consisting of a casing which is open at one side for the insertion and removal of a spool, spring-arms mounted within the casing having oppositely-curved faces adapted to embrace a spool and yieldingly bear upon opposite sides of its cylindrical surface, and a thread-passage through a wall of said casing.

2. A spool-holder of the character described, consisting of a casing which is open at one side for the insertion and removal of a spool, two pairs of spring-arms located at opposite ends of said casing and having their free ends directed toward the open side of said casing, said arms being adapted to embrace and yieldingly bear upon the edges of the end flanges of the spool at opposite sides thereof, and a thread-passage through the wall of the casing which is opposite said open side.

3. A spool-holder of the character described consisting of a casing which is open at one side for the insertion and removal of a spool, two pairs of spring-arms located at opposite ends of said casing and having their free ends directed toward the open side thereof, said arms being adapted to embrace and yieldingly bear upon the edges of the end flanges of the spool at opposite sides thereof, the arms of each pair which bear upon the same side of the spool being integrally connected together at their lower or free ends, and a thread-passage through the wall of the casing opposite its open side.

4. A spool-holder of the character described, consisting of a casing which is open at one side for the insertion and removal of a spool, spring-arms having oppositely-curved faces adapted to embrace a spool and yieldingly bear upon opposite sides of its cylindrical surface, said arms being formed integral with a plate which rests against the inner surface of the casing opposite its open side, and a guide-tube for the passage of the thread from the spool, said tube being inserted through said casing and said plate and forming an eyelet which connects the plate to the casing.

5. A spool-holder of the character described, consisting of a casing provided with an opening for the passage of the thread and a guide-tube which extends outwardly from the outer surface of the casing, and a thread-gripping device located on the wall of the casing at a distance from said guide-tube, said casing being provided at both sides of the space between the guide-tube and gripping device with outwardly-extending flanges.

6. A spool-holder of the character described, consisting of a casing provided with an aperture for the passage of the thread, and with a slot, and a plate secured to the inner surface of the casing and provided with arms which constitute spring-pressers and with a tongue which passes outwardly through said slot and forming with the edges or walls of the latter a thread-gripping device.

7. A spool-holder embracing a casing which is open at one side for the insertion and removal of a spool, said casing having a slot in the wall thereof which is opposite said open side, a plate within the casing provided with spring-arms for yieldingly engaging and holding a spool, and also with a tongue which passes outwardly through said slot, and a guide-tube for the thread forming an eyelet which secures the plate to the casing and which projects from the outer surface of the casing.

8. A spool-holder of the character described, consisting of a casing which is open on one side only for the insertion and removal of a spool, and which is provided with a slot in the wall opposite the open side, a plate within the casing provided with arms which form spring-pressers and with a tongue which passes outwardly through said slot and forms with the edges or walls of the slot a thread-gripping device, and an eyelet which secures said plate to the casing and which affords an exit-passage for the thread.

9. A spool-holder of the character described comprising a casing adapted to receive a spool and having interior spool-holding means, and having an aperture for the passage of the thread therefrom, said casing being provided with a slot or opening adapted to receive and hold a portion of a block of wax applied to the exterior of the casing.

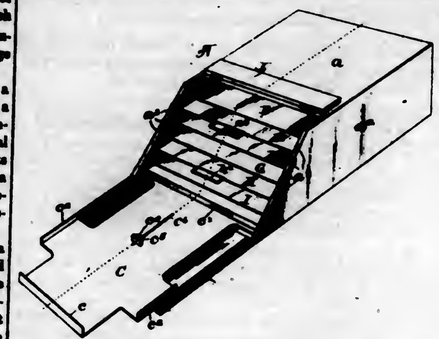
10. As an article of manufacture, a spool-holder comprising a casing open on one side only for the insertion and removal of a spool, means within said casing for yieldingly holding a spool therein, said casing being provided with an aperture for the passage of thread from the spool, said aperture being located in the wall which is opposite the open side of said casing, said wall being joined on opposite edges by oblique walls, upon one of which is arranged a block of wax, the other of said oblique walls being provided with integrally-formed loops beneath which is inserted a strip of fabric, substantially as described.

810,293. PAPER-CABINET. JOHN W. MEAKER, Chicago, Ill., assignor, by mesne assignments, to Meaker Sales Company, a Corporation of Michigan. Filed Apr. 26, 1904. Serial No. 204,061.

Claim.—1. A paper-cabinet provided with a plurality of superposed paper-receiving shelves, with a sliding paper-support provided with a lateral and end ledges and with an adjustable paper-stop.

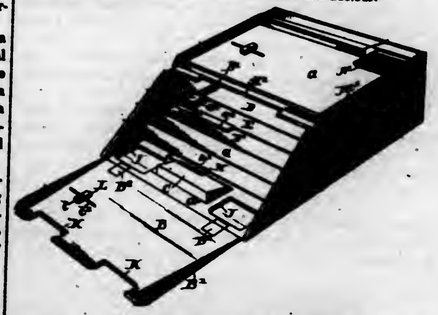
2. A paper-cabinet provided with a plurality of shelves the front edges of which are arranged in stepped or overlapped relation, the cabinet having a top wall which terminates at the rear of the front edge of the upper shelf and is provided with a hinged flap.

3. A paper-cabinet comprising bottom, top, side and end walls and having an inclined front, a series of shelves in said cabinet having their front edges in stepped relation, a cover hinged to the front edge of said bottom wall and adapted to form a forward continuation thereof when in its horizontal position, and a horizontal paper-support located below the lowermost shelf above the bottom wall and adapted to slide into and out of the cabinet and to rest upon the said cover when the latter is in its horizontal position and the said paper-support is in its extended position.



4. A paper-cabinet provided with a series of superposed paper-receiving shelves, the front edges of which are arranged in stepped relation, and having a cover hinged to the front edge of its bottom wall and a horizontal paper-support located beneath said shelves and adapted to slide into and out of the cabinet and to rest upon the cover when the latter is in its horizontal position and said paper-support is extended, said paper-support being provided with end and side ledges.

810,294. PAPER-CABINET. JOHN W. MEAKER, Chicago, Ill., assignor, by mesne assignments, to Meaker Sales Company, a Corporation of Michigan. Filed July 11, 1904. Serial No. 216,149.



Claim.—1. A paper-cabinet embracing connected bottom, side and top walls having an open front inclined upwardly and rearwardly and provided with a plurality of paper-receiving shelves, the front edges of which are arranged in stepped relation, and with a flap hinged to the front edge of the bottom wall and, when swung downwardly into a horizontal position, forming a forward extension of the bottom wall and constituting with the front marginal portion of said bottom wall a paper-support, said cabinet also having on its lower wall at some distance inwardly from the edge thereof a ledge forming a stop for the inner edges of sheets of paper resting on the paper-support, and the said flap having a lateral guide ledge or shoulder for the side edges of said sheets of paper.

2. A paper-cabinet embracing connected bottom, side and top walls, having an open front inclined upwardly and rearwardly and provided with a plurality of paper-receiving shelves, the front edges of which are arranged in stepped relation, and with a flap hinged to the front edge of the bottom wall and, when swung downwardly into a horizontal position, forming a forward extension of the bottom wall and constituting with the front marginal portion of said bottom wall a paper-support, said cabinet also having on its lower wall at some distance inwardly from the edge thereof a ledge forming a stop for the inner edges of sheets of paper resting on the paper-support, and the said flap having a lateral guide ledge or shoulder for the side edges of said sheets of paper and also a laterally-adjustable stop.

3. A paper-cabinet provided with a series of superposed shelves, a flap hinged to the front edge of its lower wall, a ledge on the forward part of the bottom wall, said bottom wall having an aperture located between the side margin of the said bottom wall and the adjacent end of said ledge.

810,295. PAPER-CABINET. JOHN W. HEARNE, Chicago, Ill., assignor, by mesne assignments, to Meaker Sales Company, a Corporation of Michigan. Filed July 11, 1904. Serial No. 216,188.

Claim.—1. A paper-cabinet provided with superposed shelves having guide shoulders or ledges which extend from front to rear of the shelves and which are arranged in laterally-offset relation to each other.

2. A paper-cabinet provided with superposed shelves having guide shoulders or ledges which extend from front to rear of the shelves and are arranged in offset relation; said shelves also having in their front margins notches of progressively-increasing width from the bottom to the top of the cabinet.

3. A paper-cabinet provided with superposed shelves and having a top wall which forms a paper-support and is provided with a rear ledge and with an adjustable lateral ledge.

4. A paper-cabinet comprising superposed shelves, and having a top wall forming a paper-support, said top wall having stationary rear and lateral guide-ledges and an adjustable lateral stop.

5. A paper-cabinet comprising superposed shelves and a paper-support provided with rear and lateral guide-ledges, and with an aperture in line with the front surface of the rear guide-ledge.

6. A paper-cabinet provided with superposed shelves and having a top wall which forms a paper-support and is provided with rear and lateral guide-ledges, said top wall having an aperture located in line with the said rear guide-ledge.

7. A paper-cabinet provided with a series of superposed shelves, provided with lateral guide stripe or ledges which are adjustable laterally on the shelves.

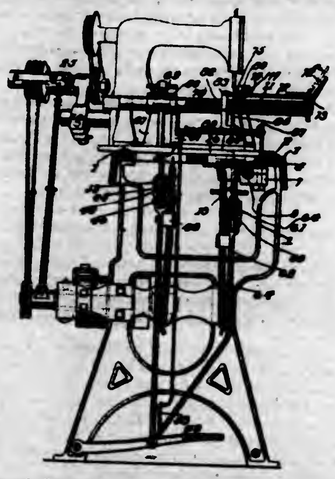
8. A paper-cabinet provided with a series of superposed shelves, provided with rear guide-ledges that are adjustable toward and from the front edges of the shelves and with lateral guide-ledges that are adjustable laterally on said shelves.

810,296. STAND OR TABLE. JOHN W. HEARNE, Chicago, Ill., assignor, by mesne assignments, to Meaker Sales Company, a Corporation of Michigan. Filed Aug. 1, 1904. Serial No. 218,893.

Claim.—1. A table or stand having an open top and a pivotally-mounted leaf adapted to close said top, and to swing outwardly to form an extension of said table, a swinging support normally below said top having its pivotal supports located parallel with and adjacent to the ends of said leaf, suitable connections between said leaf and said support whereby the latter will be raised by the opening movement of said leaf, said leaf having a marginal edge which engages the swinging support between its axial line and its free end when said leaf is in its open position.

2. A table or stand having an opening in its top and a reversible leaf pivotally mounted in said opening, adapted to close the same and to be swung upwardly and outwardly to form an extension thereof, said leaf having its pivotal supports located at a distance from its marginal edge, a swinging support normally below said opening having its pivotal connections located adjacent to the axis of said leaf, a chain or cord having one end connected to said leaf and the other end connected to the free end of said support, a guide-pulley for said chain located at or near the rear end of said opening, whereby said support will be raised by the opening movement of said leaf, said leaf having a marginal edge adapted to move under a portion of said support to complete the lifting movement and maintain said support in its elevated position.

810,297. BUTTONHOLE-SEWING MACHINE. HENRY C. MILLER, Waterford, N. Y. Filed Apr. 19, 1902. Serial No. 103,749.



Claim.—1. In combination, two buttonhole cutting and stitching machines, gages, means for introducing a collar to the gages, devices for holding a collar while the machines simultaneously cut and stitch two buttonholes at predetermined points, mechanism for simultaneously operating the holding devices, and mechanism for operating the two machines.

2. In combination, two buttonhole cutting and stitching machines, a centralizing device, mechanism for holding a collar while the machines are operated simultaneously to cut and stitch buttonholes at predetermined points, and mechanism for operating the two machines.

3. In combination, buttonhole cutting and stitching machines, means for positioning a collar, gages, and devices for holding the collar for the machines to operate upon simultaneously to cut and stitch buttonholes in selected locations, means for operating the holding devices, and means for operating the buttonhole cutting and stitching machines.

4. In combination, a pair of buttonhole cutting and stitching machines, mechanism for introducing a collar to the machines, means for gaging the collar, means for clamping the collar after it has been gaged, and means for operating the pair of stitching and cutting machines.

5. In combination, a pair of buttonhole cutting and stitching machines, means located between the machines for positioning a collar, means simultaneously starting the machines, and means for independently starting the machines.

6. In combination, a pair of independently pivotally mounted buttonhole cutting and stitching machines, means for positioning a collar to be operated upon by the machines, mechanism for increasing or decreasing the distance between the machines, and mechanism for operating the pair of machines.

7. In combination, a pair of pivotally-mounted buttonhole cutting and stitching machines, means for positioning a collar to be operated upon by the machines, means for adjusting the machines to or from each other, mechanism for operating the machines, mechanism for simultaneously starting the machines and mechanism for independently starting the machines.

8. In combination a frame, a pair of buttonhole cutting and stitching machines having cutting-blades and stitching mechanism, the machines being pivotally mounted on the frame, the center of the cutting-blades of the respective machines being in alinement with the pivots, and means for positioning a collar to be operated upon.

9. In combination, a frame, a pair of buttonhole cutting and stitching machines having cutting-blades and stitching mechanism, the machines being independently mounted on the frame, the center of the cutting-blades of the respective machines being in alinement with the pivots, means for adjusting the machines to or from each other, and mechanism for positioning a collar to be simultaneously operated upon by the machines.

10. In combination, a pair of buttonhole cutting and stitching machines independently pivoted, each having a cutting-blade, and needle-stitching mechanism, the center of the cutting-blades being in alinement with the pivots, mechanisms for adjusting the machines to or from each other, means for positioning a collar to be simultaneously operated upon by the machines, mechanism for simultaneously operating the two machines, mechanism for simultaneously starting the machines and mechanism for independently starting the machines.

11. In combination, a frame, ways in the frame, a pair of buttonhole-stitching machines mounted to slide in the ways, each buttonhole-machine having cutting and stitching mechanism, means for increasing or decreasing the distance between the pair of buttonhole-machines, means for introducing a collar to the machines, gages, and means on each machine for holding a collar against the gages while buttonholes are being stitched and cut at predetermined points, and means for simultaneously operating the holding means.

12. In combination, a frame, ways in the frame, a pair of buttonhole-stitching machines mounted to slide in the ways, a rod having right and left hand threads, said threads engaging the buttonhole-stitching machines and adapted to adjust them in the ways to or from each other, means for positioning a collar to be simultaneously operated upon by the machines, mechanism for holding the collar after it has been positioned, and mechanism for starting the two machines.

13. In combination, buttonhole-stitching machines having starting mechanisms, flexible connections suspended from the starting mechanisms, a bar common to said connections, and means connected to said bar for operating it.

14. In combination, buttonhole-stitching machines having starting mechanisms, connections attached to the starting mechanisms, a bar common to said connections but normally out of contact therewith, and means connected to the bar for simultaneously actuating it to contact with and operate the connections attached to the starting mechanisms.

15. In combination, buttonhole-stitching machines having starting mechanisms, connections attached to the starting mechanisms, a bar common to said connections, means connected to said bar for actuating it to contact with and simultaneously operate the connections attached to the starting mechanisms, and a device for operating the starting mechanism of each stitching-machine, each operating device being positioned to actuate the bar and operate only the starting mechanism of a particular machine.

16. In combination, buttonhole-stitching machines having starting mechanisms, a bar positioned to simultaneously move the starting mechanisms, means connecting the bar and the starting mechanisms and a connection for moving the bar.

17. In combination, buttonhole-stitching machines having starting mechanisms, connections fastened to said starting mechanisms, means common to said connections for simultaneously operating the stitching-machines, and means for independently operating a single machine.

18. In combination, a pair of buttonhole-stitching machines, provided with means for clamping a collar, a centralizing device for positioning the center of the collar relative to the stitching-machines, said centralizing device comprising a table, an arm carrying a detent, means for holding the arm and detent in operative position and means for releasing the arm and detent.

19. In combination, a pair of buttonhole-stitching machines, means for holding a collar, and a centralizing device for positioning the center of the collar relative to the stitching-machines, said centralizing device comprising a table and a detent to engage the collar.

20. In combination, a pair of buttonhole-stitching machines, means for holding a collar, and a centralizing device for positioning the center of the collar relative to the stitching-machines, said centralizing device comprising a table, a detent, and means for locking the detent while engaging the collar.

21. In combination, a pair of buttonhole-stitching machines, means for holding a collar, and a centralizing device for positioning the center of the collar relative to the stitching-machines, said centralizing device comprising a table, a detent, means for holding the detent in contact with the collar, means for throwing the detent out of engagement with the collar when released, and means for actuating the detent-holding means.

22. In combination, a pair of buttonhole-stitching machines, gages adjacent the machines with which a collar engages, clamps for holding the collar after its position has been gaged, and a centralizing device for positioning the center of the collar relative to the stitching-machines, said centralizing device comprising a table, a detent to engage the collar, and means to disengage the detent from the collar.

23. In combination, a pair of buttonhole-stitching machines having starting mechanisms provided with flexible connections, connecting means common to both said flexible connections for simultaneously actuating them, and means for restoring the connecting means to normal position.

24. In combination, a frame having ways, a pair of buttonhole-stitching machines carried by the ways and connected together, a collar-support intermediate the pair of buttonhole-stitching machines, means for simultaneously moving the machines to or from each other an equidistance from a predetermined point on the collar-support, a corresponding scale and indicator adjacent each machine to indicate the adjustment of the machines, gages, means for holding a collar, and means for operating the two stitching-machines to stitch two buttonholes in the collar.

25. In combination, a frame having ways, a pair of buttonhole-stitching machines carried by the ways, means connecting the two machines together to move them to or from each other, a corresponding scale and indicator adjacent each machine, a pivoted mounting for each machine, and a corresponding scale and indicator adjacent each machine to indicate the relative angular position the machine will make buttonholes.

26. In combination, a pair of buttonhole-stitching machines, means for locating a collar, means imparting a simultaneous motion to the machines, means for simultaneously starting the machines, a detent for centralizing the collar, means for holding the detent in operative position and means for releasing the detent, said latter means being operated by the means for simultaneously starting the machines.

27. In combination, a pair of buttonhole-stitching machines, means adjacent each machine for gaging and holding a collar, a centralizing device for positioning the center of the collar relative to the stitching-machines, said centralizing device comprising a rod provided with a table, a spring-actuated arm having a detent to engage the collar, a latch for engaging the arm, a tilting arm to engage the latch, means for tilting the arm and means for simultaneously starting the stitching-machine.

28. In combination, a pair of buttonhole-stitching machines, means adjacent to each machine for gaging a collar, means for clamping the collar after it is gaged, and an adjustably-mounted centralizing device intermediate the machines for positioning the center of the collar relative to the stitching-machines.

29. In combination, a pair of buttonhole-stitching machines, and an adjustably-mounted centralizing device interposed to the stitching-machines for positioning the center of the collar relative to the stitching-machines, said device comprising a table, and spring-actuated arm, having a detent to engage a collar.

30. In combination, a pair of pivotally-mounted buttonhole cutting and stitching machines each machine having a cutting-blade and stitching mechanism, the center of each cutting-blade being in alinement with the center of the pivotal mounting of each machine, an adjustably-mounted centralizing device, and means for positioning a collar to simultaneously receive two buttonholes after it has been centralized.

31. In combination, a pair of buttonhole-stitching machines mounted to be adjusted toward or from each other, and pivoted to be turned horizontally and fixed, an adjustably-mounted centralizing device for positioning the center of the collar relative to the stitching-machines, and means for gaging a collar after it has been centralized.

32. In combination, a pair of buttonhole-stitching machines

mounted to be adjusted in a straight line to or from each other, and pivoted to be turned horizontally and fixed, an adjustably-mounted centralizing device for positioning the center of the collar relative to the stitching-machines, said centralizing device adapted to be moved at right angles to the straight-line adjustable movement of the stitching-machines.

33. In combination, a pair of buttonhole-stitching machines, mounted to be adjusted toward or from each other, and pivoted to be turned horizontally and fixed, a rod having right-and left hand threads to adjust the machines toward or from each other, an adjustably-mounted centralizing device comprising a bar mounted in bearings and provided with a table, and a spring-arm carrying a detent to engage a collar, a latch to engage the arm, and means for disengaging the arm from the collar.

34. In combination, a pair of buttonhole-stitching machines, each machine mounted to be pivotally turned horizontally and fixed, means for adjusting the machines toward or from each other, an adjustably-mounted centralizing device comprising a detent and means for latching the detent, means for starting the two machines simultaneously, said means operating the detent-latch to disengage the detent from the collar.

35. In combination, a pair of buttonhole-stitching machines having clamping mechanisms to hold the end portions of a collar, a centralizing device comprising a table, and an arm carrying a detent, and adapted to be folded down on the table, one or more devices extending outwardly from the arm and adapted to level the collar toward its ends when the arm is folded down.

36. In combination, a pair of buttonhole-stitching machines having clamping mechanisms to hold the end portions of a collar, a centralizing device comprising a table, and an arm carrying a detent and adapted to be folded down on the table, one or more adjustably-mounted devices extending outwardly from the arm and adapted to level the collar toward its ends when the arm is folded down.

37. In combination, a pair of buttonhole-stitching machines, mechanism for operating the machines, mechanism for simultaneously starting the two machines, mechanism for independently starting either of the machines, a cloth-clamping device adjacent each machine, means for holding the clamping devices down, and means for simultaneously releasing the clamping devices.

38. In combination, a pair of buttonhole-stitching machines, mechanisms for operating the machines, means for centralizing a collar relative to the stitching-machines, and means coacting with the centering means for leveling the collar toward the stitching-machines.

39. In combination, a buttonhole-stitching machine, means for positioning a collar to be operated upon by the machine, a gaging device, and means coacting with the collar-positioning means for leveling the collar toward the stitching-machine.

40. In combination, a pair of buttonhole-machines, each machine comprising essentially a stitching mechanism and a cutting-blade, said machines pivoted to be turned to make buttonholes at varying predetermined angles, and means for simultaneously adjusting the machines toward or from each other, without altering the predetermined angular adjustment of the cutting and stitching mechanism.

41. In combination, a pair of buttonhole-machines, each machine comprising essentially a stitching mechanism and a cutting-blade, each machine being pivoted to be independently turned to make buttonholes at varying predetermined angles, and means for simultaneously adjusting the machines toward or from each other without altering the predetermined angular adjustment of the cutting and stitching machines.

42. In combination, a pivotally-mounted buttonhole-machine comprising essentially a cutting-blade and stitching mechanism, the pivot of the machine being in alinement with the center of the cutting-blade while the line of stitching of the buttonhole is coincident with the center of the pivot means mounted independent of the cutting and stitching mechanism for holding an article to be stitched.

43. In combination, a collar-support, a bed-plate having ways, a pivotally-mounted base-plate, an adjustable guide-block working in said ways, a pivot connecting the swiveling base-plate and the guide-block, a buttonhole-stitching machine having a reciprocating needle mounted on said base-plate, and having the path of reciprocation of the needle coincident with the axis of said pivot.

44. In combination, a collar-support, a bed-plate formed with lengthwise ways, a movable guide-block working in said ways, mechanism for moving said guide-block in either direction, a swiveling base-plate supported on said bed-plate, a pivot connecting the base-plate with the guide-block, a buttonhole-stitching machine provided with a reciprocating needle, and mounted on said base-plate with the driving mechanism thereof relatively to one side of the center of the said pivot, and the path of the reciprocation of the needle coincident with the axis of said pivot.

45. In a stitching-machine, the combination with a collar-support, a bed-plate having ways, a guide-block adapted to be moved in either direction between said ways, a movable base-plate pivotally mounted on said guide-block, a buttonhole-stitching machine supported on said base-plate mechanism for moving said guide-block longitudinally, and means for indicating the movement of said block.

46. In combination a bed-plate, a guide-block adjustable in either direction in relation to said bed-plate, mechanism for moving said guide-block and holding it stationary when adjusted, a base-plate pivoted on said guide-block, and a buttonhole-stitching machine mounted on said base-plate, a stationary collar-supporting plate adapted to receive and support the middle portion of a collar, a detent adapted to hold a collar at its middle portion, and mechanism to hold said detent in engagement with the collar.

47. In a collar-stitching machine, the combination with a bed-plate, two movable guide-blocks, two base-plates, respectively pivoted on said guide-blocks and adapted for simultaneous movement in either direction, two similar buttonhole-stitching machines, having reciprocating needles, the machines respectively mounted on said movable guide-blocks, and pivotally connected therewith, the path of the reciprocating needles being coincident with the axis of the respective pivots, a driven mechanism actuating the operating mechanism of each machine, and a driving mechanism.

48. In a collar-stitching machine, the combination with two similar buttonhole-stitching mechanisms, driving mechanisms adapted to simultaneously actuate the respective machines, two pivotally-mounted base-plates respectively supporting said machines, two movable guide-blocks, adapted to be moved to equal distances and in opposite directions, and pivoting devices adapted to hold said base-plates with said guide-blocks, the axial lines of the needles being coincident with their respective pivoting devices, mechanism between the pivotal points for supporting the middle portion of the body of a collar, mechanism adapted to clamp the respective end portions of the collar, and mechanism adapted to move said collar, alternately, in opposite directions in relation to the said needles and to a distance equal to the length of a buttonhole.

49. In a collar-stitching machine, the combination with a bed-plate, two buttonhole-sewing machines supported on said bed-plate and adapted respectively to be turned in opposite directions each from a center coincident with the path of center of its needle, simultaneously-operated driving mechanism, a collar-supporting device adapted to support the middle portion of the collar midway between the respective needles of said machines, a detent adapted to engage with the middle portion of the collar, and mechanism for releasing the detent from its engagement with the collar.

50. In a collar-stitching machine, the combination with two similar buttonhole-stitching machines adapted to have the operating mechanism actuated simultaneously, a cloth-clamping mechanism on each machine adapted to clamp the respective ends of a collar to be stitched, a collar-supporting table between said two cloth-clamping mechanisms, a detent adapted to be engaged with the middle portion of a collar when placed on said supporting-table and be released from the same, means holding the detent in operative position a driven mechanism for simultaneously actuating the said machines, and mechanism adapted to move both cloth-clamping means simultaneously and alternately in opposite directions during the time the needle is being operated.

51. In a buttonhole-stitching machine, the combination with a table adapted to support the middle portion of a collar, an arm adapted to fold down on said table in a line transverse to the length of the collar, one or more leveling devices secured to said arm, and adapted to bear on a collar to flatten it out toward the outer ends of the collar.

52. In a buttonhole-stitching machine, the combination with cloth-clamping mechanism to hold the end portions of a collar, of a table adapted to support the middle portion of a collar, a detent operated for holding a collar on said table, and one or more cloth-leveling devices extending in opposite directions from the middle of the collar-supporting table.

53. In a collar-stitching machine, the combination with buttonhole-stitching machines operated by suitable driving mechanism, cloth-clamping mechanisms adapted to respectively clamp an end of a collar, of a collar-supporting table adapted to hold the middle portion of a collar on a plane with the lower clamping-plate of each of said cloth-clamping mechanisms, a collar-leveling device between said two cloth-clamping mechanisms adapted to flatten a collar longitudinally on the table, and a detent adapted for engagement with the middle of the collar.

54. In a collar-stitching machine, the combination with a supporting-table adapted to support the middle portion of a collar, a detent for engagement with a collar on said table, a buttonhole-stitching mechanism adapted to be engaged with an end portion of a collar, a gage-finger adapted to be adjusted and set for gaging the distance the end buttonhole is to be from a predetermined point in the collar.

55. In a collar-sewing machine, the combination with a pair of sewing-machines, means for centering and holding the article that predetermined points thereon may be operated upon by the sewing-machines to form buttonholes, means holding said latter means in operative position, mechanism for releasing the articles from said latter means, and mechanism for moving the article to be operated upon simultaneously and in the same direction.

56. In a collar-stitching machine, the combination with a pair of buttonhole-sewing machines, a material-supporting device located between the two sewing-machines, mechanism on said supporting device for locating and holding the material relative to the pair of sewing-machines and prior to the time the sewing-machines are operated, means for releasing said locating and holding mechanism, and mechanism for simultaneously moving the material when released to form and sew two buttonholes.

57. In a collar-stitching machine, means for centering the material with relation to the stitching mechanisms, duplicate stitching mechanisms for the ends of the material, and means for adjusting said stitching-machines to alter the direction of their lines of stitching.

58. In a collar-stitching machine, a bed-plate duplicate cutting and stitching machines, means for supporting material intermediate the duplicate stitching-machines, means for simultaneously moving the machines, and means for changing the radial positions of the stitching-machines with relation to the material.

59. In a collar-stitching machine, a collar-support, a frame, ways on the frame, duplicate guide-blocks adjustably carried by the ways, a stitching-machine fixed on each guide-block, and a server for simultaneously moving said guide-blocks in opposite directions on the ways, whereby to change the relative positions of the stitching mechanism.

60. In combination, a pair of buttonhole cutting and stitching machines, means for increasing or decreasing the distance between the two machines, starting mechanism for each stitching-machine, a bar, means connecting the bar and the starting mechanisms, and operative means connected to the bar.

61. In a collar-buttonhole-stitching machine, the combination with a pair of buttonhole-stitching machines which are adapted to be simultaneously moved toward or from each other, means for adjusting said pair of machines to alter the direction of their respective stitching-lines, means for holding the end portion of a collar in operative relation to the stitching mechanisms of the respective machines, and means for moving the body of the collar lengthwise in one direction a distance equal the length of a buttonhole and then in reversed direction a like distance.

62. In combination, a pair of buttonhole-stitching machines, each machine comprising essentially a cutting-blade and a stitching mechanism, means supporting a piece of material to simultaneously receive two buttonholes, means to permit the adjustment of the buttonhole-stitching machines independently to vary the angles of the buttonholes in relation to a medial line, and means adjacent the machines for holding the material while the buttonholes are formed.

63. In combination, a pair of buttonhole-stitching machines, each machine comprising essentially a cutting device and a stitching mechanism, means for increasing or decreasing the space between the two machines, mechanism for simultaneously operating the two machines and mechanism for independently operating either of the machines.

64. In combination, a pair of buttonhole cutting and stitching machines, means for increasing or decreasing the distance between the two machines, starting mechanism for each machine, a bar, means connecting the starting mechanisms and the bar, operative means connected to the bar, and means for restoring the operative means and bar to normal position after they have been operated.

65. In combination, a pair of buttonhole-stitching machines, each machine comprising essentially a cutting device, a stitching mechanism, a cloth-clamp and independent starting mechanism, and mechanism for simultaneously operating the two starting mechanisms.

66. In combination, two buttonhole cutting and stitching machines, an adjustable collar-centralizing device for positioning the center of the collar relative to the stitching-machines and mechanism for operating the two machines.

67. In combination, a pair of buttonhole-stitching machines, means adjacent each machine for gaging a collar, means for clamping the collar after it is gaged, and a device between the machines to introduce a collar to the gages to receive buttonholes at predetermined distances from the said device.

68. In combination, a buttonhole cutting and stitching machine, a gage, a movable collar-introducing device, means carried by said device for engaging a collar when delivering the latter to the stitching-machine, and means to increase or decrease the distance between the collar-engaging means and the stitching-machine.

69. In combination, a pair of buttonhole cutting and stitching machines, each machine having a cloth-holder, and a device between the two machines to introduce a collar to be clamped by the cloth-holders, and mechanism operating the stitching-machines.

70. In combination, two buttonhole cutting and stitching machines, a gage on one of the buttonhole-machines to gage the right-hand end of a collar, a gage on the other buttonhole-machine to gage the left-hand end of the collar, means for introducing a collar to the gages, devices for holding the ends of the collar while the two machines cut and stitch two buttonholes at predetermined points therein, mechanism for independently operating either machine.

71. In combination, two buttonhole cutting and stitching machines, a gage to gage the right-hand end of a collar, on one of the buttonhole-machines, a gage on the other buttonhole-machine to gage the left-hand end of the collar, means movable to or from the buttonhole-machine for introducing a collar to the gages, devices for holding the opposite end portions of a collar while being cut and stitched at predetermined points therein, mechanism for simultaneously operating the two buttonhole-machines, and means for simultaneously releasing the collar-holding devices.

72. In combination, a pair of buttonhole cutting and stitching machines, each machine comprising a stitching mechanism and a cutting-blade, means for supporting a collar to be operated upon by the pair of buttonhole-machines, means for securely holding the opposite ends of the collar, said means being located below the cutting-blade and needles of the respective buttonhole-machines, mechanism for simultaneously starting both machines, and mechanism for independently starting either machine.

73. In combination two buttonhole-machines, each machine provided with starting mechanism, a horizontal bar suspended beneath the said machines, connections between the ends of said bar and the starting mechanisms of the two machines, means for making both ends of the bar operative for simultaneously starting the machines, and mechanisms for making one end of the bar inoperative and the other end operative for independently starting either machine.

74. In combination, two independent sets of buttonhole-sewing mechanisms, each complete and operative in itself to make a buttonhole, each set having a clamp-plate and a gage, the gage of each set being similar to the gage of the other set, said gages being provided with means by which they are adapted to receive a collar therebetween and engage the same, the clamp-plates being cooperative to secure the collar in position relatively to the gages, and common means for starting both sets of sewing mechanisms.

75. In combination, a pair of buttonhole-machines, each machine comprising a needle, a cutting-blade and a clamping device, a centralizing device, an adjustable gage to gage the right-hand end of a collar on one buttonhole-machine, an adjustable gage to gage the left-hand end of the collar on the other buttonhole-machine, mechanism simultaneously opening the cloth-clamping devices to receive the end portions of a collar, the gages being located below the normal position of the cutting-blades and needles, mechanism for starting the machines, means for operating the centralizing devices, and means for automatically closing the cloth-clamping devices.

76. In combination, two buttonhole cutting and stitching machines, each machine comprising a stitching mechanism and a cutting-blade, a gage to gage the right-hand end of a collar on one of the machines, a gage to gage the left-hand end of a collar on the other machine, a cloth-clamping device on each machine, means for independently operating either cloth-clamping device, mechanism for simultaneously operating the cloth-clamping devices, mechanism for simultaneously operating the two machines, and mechanism for independently operating the machines.

77. In combination, a frame having ways, guide-blocks working in said ways, a pair of buttonhole-stitching machines mounted on said guide-blocks, means for moving the machines to or from each other, a corresponding scale and indicator adjacent each machine, a gage to gage the right-hand end of a collar on one of the machines, a gage to gage the left-hand end of the collar on the other

machine, means for holding the opposite ends of a collar, and means for simultaneously operating the two machines for cutting and stitching buttonholes.

78. In combination, a frame provided with two separate ways, a guide-block in each way, a buttonhole-machine mounted on each guide-block, mechanism for increasing or decreasing the distance between the two machines, a scale and an indicator for indicating the movement of both machines, a pivot connection between each machine and its guide-block, an angle-recording scale and an indicator adjacent each machine for indicating the angular position each machine is to be set in relation to the other for forming buttonholes at proper angles and means for holding the machines in position after they have been set.

79. In combination, a pair of buttonhole-sewing machines, one machine having a gage to receive the right-hand end of a collar, the other machine having a gage to receive the left-hand end of a collar, the gage of one machine being similar to the gage of the other machine, each machine having a cloth-clamping plate, means to introduce a collar between the gages, and mechanism for operating the pair of buttonhole-sewing machines.

80. In combination, two buttonhole-sewing machines, each machine comprising stitch-forming mechanism, a work-clamp, and means for producing a relative movement between said stitch-forming mechanism and work-clamp, and a centralizing device intermediate said buttonhole-sewing machines for centralizing the article being treated relative to the stitch-forming mechanisms and deliver said article on said work-clamps.

81. In combination, two buttonhole cutting and stitching machines and a collar-centralizing device having means against which a collar is placed, said means being operable to introduce and centralize a collar between the two buttonhole-machines.

82. In combination, two buttonhole-stitching mechanisms, and centralizing means which contact with an article to be operated upon to introduce the ends of said article to the stitching mechanisms to receive buttonholes, and means operating the stitching mechanisms.

83. In combination, two buttonhole-stitching mechanisms, and a centralizing device having engaging means on a line drawn through the center between the two buttonhole-stitching mechanisms, for introducing an article to said stitching mechanisms, the points in the ends of the article receiving the buttonholes being equidistance from the engaging means of the centralizing device.

84. In combination, two buttonhole-sewing machines, each machine comprising stitch-forming mechanism, a work-clamp, and means for producing a relative movement between said stitch-forming mechanism and work-clamp, and a centralizing device for centralizing the article being treated relative to the stitch-forming mechanisms and deliver said article on the said work-clamps.

85. In combination, two buttonhole-sewing machines, each machine comprising stitch-forming mechanism, a work-clamp, and means for producing a relative movement between said stitch-forming mechanism and work-clamp, and means for introducing and positioning an article on said work-clamps to insure operation of the stitching mechanisms at predetermined points on the article from a previously-formed buttonhole.

86. In a collar and cuff buttonhole stitching machine the combination of two buttonhole-machines having their needles located in a line parallel to the axis of an adjusting-screw, an adjusting-screw for regulating the distance between the needles along said line, a plate on a fixed support intermediate the needles, a work-guide and means upon said work-guide for locating the position of the article under treatment, substantially as described.

87. In a collar and cuff buttonhole stitching machine, the combination of two button-stitching machines, a main supporting-table therefor, means for varying the distance between the needles of said machines along a line parallel to the axis of the varying means, a work-supporting plate fixed in position intermediate the needles, and a work-locating guide coöperating with said work-supporting plate, substantially as described.

88. In a collar and cuff buttonhole stitching machine, the combination of two buttonhole-machines having their needles located in a line parallel to the axis of an adjusting-screw, an adjusting-screw for regulating the distance between the needles along said line, a plate on a fixed support intermediate the needles, a work-guide, means for adjusting the work-guide in a direction across the line between the needles, substantially as described.

89. In a collar and cuff buttonhole stitching machine, the combination of two buttonhole-machines having their needles located in a line parallel to the axis of an adjusting-screw, an adjusting-screw for regulating the distance between the needles along said line, a plate on a fixed support intermediate the needles, a work-guide, a graduated scale and an index coöperating therewith, substantially as described.

90. In a collar and cuff buttonhole stitching machine, the combination of two buttonhole-stitching machines having work-clamps, a supporting-table therefor, means for varying the distance between the needles of said machines along a line parallel to the axis of the varying means, a work-supporting plate fixed in position intermediate the needles, a work-locating guide coöperating with said work-supporting plate, and means for opening the two work-clamps.

91. In a collar and cuff buttonhole stitching machine, the combination of two buttonhole-stitching machines, a supporting-table therefor, means for varying the distance between the needles of said machines, an adjustable work-supporting plate positioned intermediate the needles, and a work-locating guide coöperating with the supporting-plate.

92. In a collar and cuff buttonhole stitching machine, the combination of two buttonhole-machines, a supporting-table therefor, means for varying the distance between the needles of said machines, a plate on a fixed support intermediate the needles, a work-guide cooperating with the plate, and a graduated scale and index coöperating therewith.

93. In a collar and cuff buttonhole stitching machine, the combination of two buttonhole-machines, means for varying the distance between the needles of said machine, a support, a plate adjustably mounted on the support, a work-guide coöperating with said plate, and means for adjusting the work-guide across the line between the needles.

94. In a collar and cuff buttonhole stitching machine, the combination of two buttonhole-machines, means for varying the distance between the needles of said machines, a fixed support intermediate the two machines, an article-introducing means carried by the support including a work-guide and a locating-guide.

95. In a collar and cuff buttonhole stitching machine, the combination of two buttonhole-stitching mechanisms, a support intermediate the mechanisms, a work-supporting plate, and a work-locating guide coöperating with said work-supporting plate.

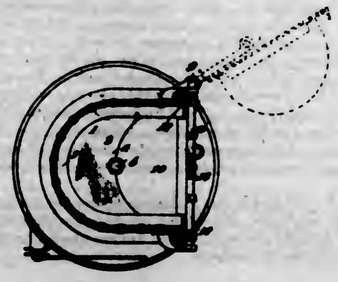
96. In a collar and cuff buttonhole stitching machine, the combination of two buttonhole-machines, means for varying the distance between the needles of said machines, a support intermediate the machines, and movable means carrying a work-guide to deliver an article to the support and the buttonhole-machines.

97. In combination, two buttonhole-stitching machines a gage to gage the right-hand end of an article, a gage to gage the left-hand end of the article, a work-supporting plate fixed intermediate the needles of the buttonhole-machines, a work-guide, means for holding the ends of a collar while the two machines form buttonholes at predetermined points therein, and means for operating the buttonhole-machines.

98. In combination, two buttonhole-stitching mechanisms, means which contact with an article to be operated upon to move and introduce the ends of said article to the stitching mechanisms to receive buttonholes, and means operating the stitching mechanisms.

99. In combination, two buttonhole-stitching mechanisms, means which contact with an article to be operated upon to introduce the ends of said article to the stitching mechanisms to receive buttonholes, means operating the stitching mechanisms, and means for independently operating either stitching mechanism.

810,298. AIR-LOCK FOR CAISSONS. WILLIAM MCELVEEN, Jersey City, N. J., assignor to The Cookson Barrow and Machine Company, Jersey City, N. J., a Corporation of New Jersey. Filed June 22, 1905. Serial No. 266,493.



Claim.—1. In an air-lock for caissons, a casing having a stationary top portion extending partially over the upper end thereof, said casing having an opening in its side extending lengthwise thereof to permit of removing and replacing the bucket, and means for simultaneously closing said opening and that part of the top of the casing not covered by said stationary portion.

2. In an air-lock for caissons, a casing having a lower door, a stationary top portion extending partially over the upper end of said casing, a bushing for the hoisting-cable designed to be accommodated by the edge of said top portion in line with the center of the opening closed by said lower door, said casing having an opening in its side extending lengthwise thereof, and means for simultaneously closing said opening and that part of the top of the casing not covered by said stationary portion.

3. In an air-lock for caissons, a casing having an opening at its side extending lengthwise thereof, a door for closing said opening, and means for holding a hoisting-cable in fixed relation to said casing when said door is closed and for releasing the same when said door is opened to permit the bucket and cable to be removed through said opening.

4. In an air-lock for caissons, a casing, a fixed closure partially covering the upper end of said casing, said casing having an opening extending lengthwise thereof at its side, and a door for said opening having a closure at its upper end for coöperating with the fixed closure at the upper end of the casing.

5. In an air-lock for caissons, a casing having a stationary top portion extending partially over the upper end thereof, said top having its free edge beveled, said casing having an opening at its side, and a door for said opening having a ledge at its upper end for coöperating with the stationary top portion of said casing to form a complete closure for the upper end thereof, the edge of said ledge being designed to contact with the beveled edge of said top.

6. In an air-lock for caissons, the combination with the casing having an opening in its lower end, means for closing said opening, a stationary top portion extending partially over the upper end of said casing, a bushing removably accommodated by said top in line with the center of said lower opening, said top having portions of its inner face beveled, said casing being open throughout its side and at the part of its upper end not covered by said stop, of a door pivotally mounted upon said casing and forming a closure for said side and provided with locking devices, said door having a ledge forming a closure for the upper end of the casing and designed to be accommodated beneath the beveled portions of said top.

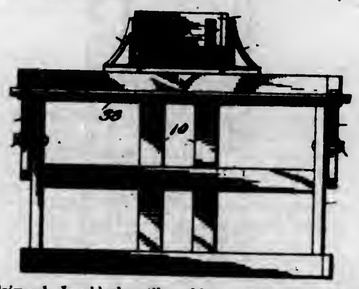
810,299. GAME APPARATUS. OLIVER E. PETTIT, Rockford, Ills. Filed Dec. 9, 1904. Serial No. 236,121.

Claim.—1. In an apparatus of the class described the combination with a board adapted for the passage of projectiles thereover, of an upwardly-extending pin carried by the board and disposed to be struck by the projectiles, a stop-board hinged to the first-named board for movement to lie thereagainst or to extend at right angles thereto, said stop-board having an opening therethrough for the reception of the pin when the stop-board is in its first-named position, means for holding the stop-board with its perforations engaged by the pin, operative mechanism carried by the stop-board, and connections between the mechanism and the pin for operation of the mechanism when the pin is struck.

2. An apparatus of the class described, comprising a dial, a shaft rotatably mounted centrally of the dial, an indicator rotatably mounted upon the shaft for movement over the dial, connections between the shaft and the indicator for movement of the latter with the former in one direction, said indicator being arranged for movement independently of the shaft in the same direction, a motor connected with the shaft for operation thereof to rotate the indicator therewith, means for holding the motor against operation, said means lying normally yieldably in operative position, and means for moving the holding means out of operative position.

3. An apparatus of the class described comprising a board adapted for the passage of projectiles thereover, a dial, a shaft rotatably mounted in the dial, an indicator rotatably mounted upon the shaft for movement over the dial, connections between the shaft and the indicator constructed and arranged for movement of the indicator with the former in one direction, said indicator being movable independently of the shaft in the same direction, a motor connected with the shaft for rotation thereof to rotate the indicator therewith, a second rotatably-mounted shaft, connections between the second shaft and the motor for operation thereby, a finger carried by the second shaft, a stop arranged for movement into and out of the path of movement of the finger, said stop when in its first-named position being arranged for engagement by the finger to hold the motor against operation, said stop lying normally in such position, and means for moving the stop out of its normal position, said means being adapted for operation by projectiles moving over the surface of the board.

810,300. MACHINE FOR MAKING BLOCKS OR TILES. DANIEL I. PETTIT and JOHN B. PETTIT, Grand Junction, Iowa. Filed Mar. 11, 1905. Serial No. 249,619.



Claim.—1. In a block or tile making machine, the combination of a frame, a table vertically movable in said frame and provided with guide-slots, a mold bottom board supported upon the frame, adjustable side boards carried by the table, carriers to which said side boards are removably attached, an eccentric-head disposed below and carried by the table, radial bars or links connected at their inner ends with said head, fastenings sliding in said guide-slots and adjustably connecting the outer ends of the links with the carriers, a lever for operating the eccentric-head, and means for raising and lowering the table.

2. In a block or tile making machine, a mold-box comprising a bottom board, side boards adjustably related to said bottom board, carriers for the boards, and brackets upon the carriers to which said boards are detachably connected, said boards being connectible with and disconnectible from the brackets by a sliding movement.

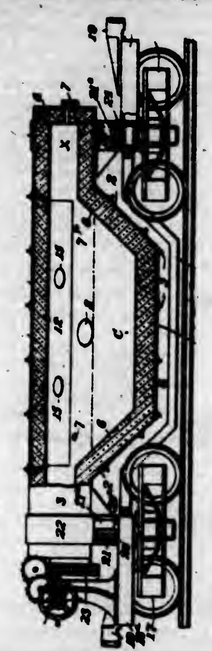
3. In a block or tile making machine, a frame, a vertically-movable table provided with guides, a mold-box bottom supported by the frame, carriers on the table engaging said guides and adapted to be adjusted toward and from said mold-box bottom, brackets supported by the carriers, removable mold sides slidably engaging the brackets, means for raising and lowering the table, and means for adjusting the carriers.

4. In a block or tile making machine, a frame having a supporting-surface, a mold-box comprising a bottom board adapted to rest upon said surface and a series of side boards adjustable with relation to said bottom board, and means for enlarging said supporting-surface to provide for the support of bottom boards of different sizes.

5. In a block or tile making machine, a frame having supporting-posts to support the bottom board of a mold-box, and brackets detachably connectible with said posts for extending the supporting-surface.

6. In a block or tile making machine, the combination of a frame having a supporting-surface, a mold-box bottom board resting on said surface, brackets adapted to be connected to the frame to increase said supporting-surface, a vertically-movable table, carriers adjustably mounted on said table with relation to the bottom board, side boards detachably connected with the carriers and adapted to coöperate with the bottom board to form a mold-box, means for raising and lowering the table, and means for simultaneously adjusting the carriers.

810,301. APPARATUS FOR STORING AND CONVEYING LIQUID METALS. GARDNER VON PEIN, Bethlehem, Pa., assignor to Bethlehem Steel Company, South Bethlehem, Pa., a Corporation of Pennsylvania. Filed May 29, 1901. Serial No. 62,502.



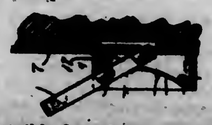
Claim.—1. An apparatus for storing and transporting molten metal consisting of a vessel and suitable trucks supporting the same, the vessel having an enlarged body portion and hollow contracted cylindrical ends containing burning-chambers and means for admitting fuel thereto, said ends turning in bearings on the trucks, substantially as set forth.

2. In an apparatus for storing and transporting molten metal, the combination of two trucks and a receptacle having a central portion extending downward between the trucks and hollow end portions extending over the trucks and adapted to turn in bearings on the trucks, substantially as set forth.

3. In an apparatus for storing and transporting molten metal, the combination of two trucks and a receptacle having a central portion extending downward between the trucks and hollow end portions extending over the trucks and adapted to turn in bearings on the trucks, and pouring-spouts on the body portion, substantially as set forth.

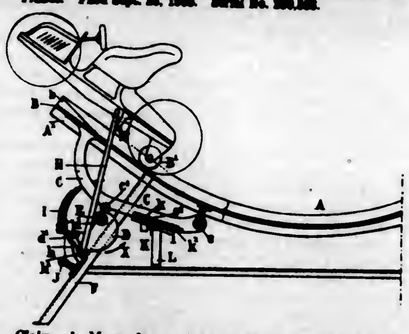
4. In an apparatus for storing and transporting molten metal, the combination of two trucks, a receptacle having a central portion extending downward between the trucks and hollow end portions extending over the trucks and adapted to turn in bearings on the trucks, a sector-gear 20 on one of the end portions, a transverse rock on the truck engaged thereby, a larger concentric sector-gear on said end portion, and a worm engaging the latter gear and turning in bearings of the truck, substantially as set forth.

810,302. SASH-HOLDER. ALBERT A. GOOD, Brookport, Ill. Filed July 25, 1905. Serial No. 271,174.



Claim.—As an article of manufacture, a window-sash lock comprising a body portion formed of a metallic plate bent to form parallel side portions and a connecting bottom piece and having sliding pairs of perforations formed in the side portions adjacent to the upper and lower ends thereof, attaching-screws engaged in the pairs of perforations, a dog pivoted upon one of the attaching-screws and extending oppositely beyond the body portion, one end of said dog being heavier than the other, a spring engaged with the other screw and a pin engaged in the side portions above the last-named screw, said spring resting against the pin and against the dog to hold the latter against downward movement of its lighter end.

810,303. SOMERSAULTING-VEHICLE. JOSEPH RAVEL and EDOUARD RAVEL, Paris, France, assignors to Charles Malden-Brunie, Paris, France. Filed Sept. 28, 1903. Serial No. 174,502.



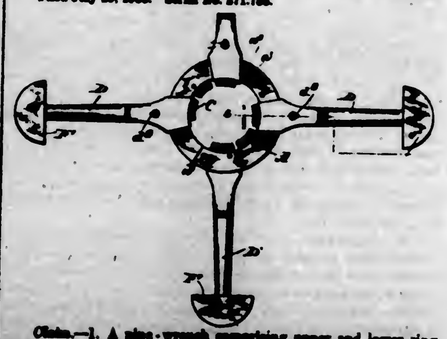
Claim.—1. Means for causing a vehicle to somersault across a gap in a track, comprising a plate arranged in the track and mounted upon a pivoted lever, a spring-actuated cam adapted to raise said lever and plate, a retaining device which prevents the rotation of the cam and means carried by the vehicle for unlatching said retaining device.

2. Means for causing a vehicle to somersault across a gap in a track, as described, comprising a plate movable upward in the track, said plate being mounted on a lever pivoted to the under side of the track, a cam adapted to raise said lever and plate, coiled springs upon the axle of the cam tending to rotate the same, a lateral projection on the cam, a lever mounted on an axle and engaging said projection, a second lever mounted on said axle and projecting into the track, and a striker upon the vehicle adapted to meet said second lever and to release the cam.

3. Means for causing a vehicle to somersault across a gap in a track, as described, comprising a cam-lifted plate in the track, said plate being mounted on a pivoted lever, and a laminated spring adapted to brake the cam movement after the plate has been raised.

4. Means for causing a vehicle to somersault across a gap in a track, as described, comprising a cam-lifted plate in the track, said plate being mounted on a pivoted lever, a sliding cushioning device upon the under side of the lever, an upstanding seat for said cushion, and an abutment on the seat.

810,304. PIPE-WRENCH. LOUIS V. REMSEN, San Bernardino, Cal. Filed July 20, 1905. Serial No. 271,752.



Claim.—1. A pipe-wrench comprising upper and lower ring shaped plates, spaced apart and divided diametrically into symmetrical sections, curved legs secured between the corresponding

ends of the sections, and extending between the plates of opposing sections, pins traversing the plates and the lugs for securing the sections together, a series of spacing-blocks secured between the plates of the sections, and provided with an inclined inner edge, springs secured to the ends of the blocks, gripping-jaws provided with inclined edges resting on the inclined edges of the blocks, and provided with transverse slots parallel to their inclined edges, screws traversing the plates of the rings and the slots, handles quadrantally arranged on the ring and comprising each a bar provided with a flanged plate, an oppositely-disposed flanged plate hinged to the bar and coacting with the first flanged plate to form a recess for receiving the rings, a lug on the second plate engaging the groove in the bar, a latch hinged to the second plate and traversing an opening in the bar, a spring on the latch, and grooved wheel-sections on the free ends of the bars.

2. In a pipe-wrench, the combination of a ring-shaped frame divided diametrically and the sections hinged together at one of their ends, means for connecting the free ends of the sections, a plurality of spring-actuated gripping-jaws slidably mounted in the frame, a plurality of handles radiating from the frame, and means whereby the individual handles may be detached from the frame.

3. In a pipe-wrench, the combination of a ring-shaped frame, comprising two symmetrical sections hinged together at one of their ends, means for securing the free ends of the sections together, a plurality of spring-actuated gripping-jaws movably mounted in the frame, and a plurality of detachable handles engaging the frame.

4. In a pipe-wrench the combination of a ring-shaped frame comprising two symmetrical sections hinged together at one of their ends, means for securing the free ends of the halves together, a plurality of spring-actuated gripping-jaws movably mounted in the frame, and means for constraining the movement of the jaws to a chord of the ring.

5. In pipe-wrenches, the combination of a circular frame having a central opening, a plurality of spring-actuated gripping-jaws movably mounted on the frame and projecting into the central opening, and means for restraining the movement of the jaws to a chord of the circular frame.

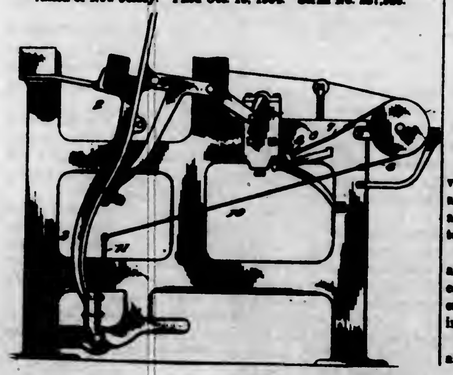
6. In a pipe-wrench, the combination of a circular frame having a central opening adapted to receive a pipe, a plurality of spring-actuated gripping-jaws movably mounted in the frame and projecting into the central opening, and means for restraining the movement of the operative face of the jaws to a tangent of the pipe.

7. In a pipe-wrench, the combination of a ring-shaped frame comprising two symmetrical sections hinged together at one of their ends, means for securing the free ends of the halves together, and a plurality of spring-actuated gripping-jaws movably mounted in the frame, and projecting beyond the inner circumference of the ring.

8. In a pipe-wrench, the combination of a circular frame having a central opening adapted to receive a pipe, and a plurality of spring-actuated gripping-jaws movably mounted in the frame and projecting into the central opening.

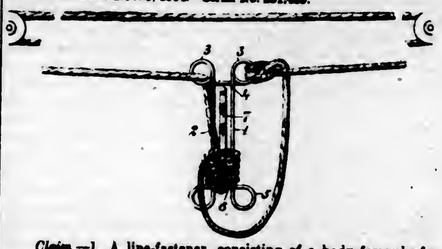
9. In a pipe-wrench, the combination of a circular frame having a central opening, a plurality of gripping-jaws projecting into the central opening, and means on the periphery of the frame for receiving a belt whereby to rotate the same.

810,305. WARP-TENSION. BOGERT REED, Stirling, N. J., assignor to Stirling Silk Manufacturing Company, Stirling, N. J., a Corporation of New Jersey. Filed Oct. 10, 1904. Serial No. 227,988.



Claim.—In a power-loom, the combination of the lay, the lay-sword, a spring-arm attached at one end to the lay-sword, the warp-beam, a brake-pulley fast to an end of the warp-beam, a brake-band coöperating with said brake-pulley, rods attached to opposite ends of the brake-band, one of said rods having an end portion threaded and passed loosely through a part of the loom-frame, set-nuts fitted to the threaded end of the rod for adjustably connecting it to the loom-frame, and means connecting the other rod to the free end of the aforesaid spring-arm, substantially as set forth.

810,306. LINE-FASTENER. DAVID W. ROBBINS, New York, N. Y. Filed Nov. 5, 1904. Serial No. 231,469.



Claim.—1. A line-fastener, consisting of a body formed of a piece of wire bent to form straight and approximately parallel side members spaced apart, each formed with a laterally-projecting coil at its upper end, the coils extending in opposite directions and connected together by a cross-bar extending across the side members, the lower ends of the side members being bent to form eyes, said eyes projecting in opposite directions and connected by a cross-bar extending across the side members, and a sinuous tongue secured to the cross-bar connecting the eyes, between the side members and extending upwardly between the said side members in direction of the cross-bar connecting the coils.

2. A line-fastener, comprising straight and approximately parallel side members spaced apart, a pair of oppositely-arranged eyes at each end of the side member, the eyes of each pair projecting in opposite direction, a cross-bar connecting the eyes of each pair of eyes and extending across the side members, and a spring-tongue secured to one cross-bar between the side members, and extending between the said side members in direction of the other cross-bar.

3. A line-fastener, comprising two straight and approximately parallel side members, spaced apart, said members being connected together near each end by a cross-bar, and provided at one end with a pair of oppositely-arranged eyes, the eyes projecting in opposite directions, and a spring-tongue secured to one cross-bar between the side members, and extending between the said side members in direction of the other cross-bar.

810,307. TOOL-HOLDER. PEARL H. ROBINSON, Shelton, Conn., assignor to The O. K. Tool Holder Company, Shelton, Conn., a Corporation of New York. Filed May 29, 1905. Serial No. 262,744.

Claim.—1. A tool-holder comprising a head having a transverse recess, an undercut abutment at the forward end of the recess, an inclined carrier at the back of the recess, a slide upon the carrier adapted to engage a tool, and means for forcing the slide against a tool to lock it in place in the holder.

2. A tool-holder comprising a head having a transverse recess, an undercut abutment at the forward end of the recess, an inclined carrier at the back of the recess, a slide upon the carrier adapted to engage the tool, a spring acting to raise the slide and means for forcing the slide against the carrier to lock it in place in the holder

3. A tool-holder comprising a head having a transverse recess, an inwardly-inclined undercut abutment at the forward end of the

recess, an inclined carrier at the back of the recess, a threaded post, a spring-actuated slide upon the carrier adapted to engage a tool and a locking-nut on the post adapted to bear against the slide and force it against the tool to lock the latter in place in the recess.

4. A tool-holder comprising a head having a transverse downwardly and rearwardly inclined recess, an undercut inwardly-inclined abutment at the forward end of the recess, an inclined carrier at the back of the recess, a slide upon the carrier whose forward end is a downwardly and rearwardly inclined wall and means for forcing the slide against a tool to lock it in the recess.

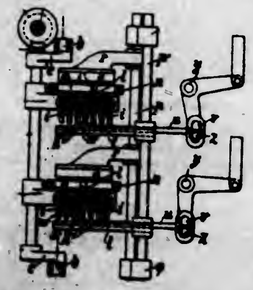
5. A tool-holder comprising a head having a transverse recess, an undercut abutment at the forward end of the recess, an inclined carrier at the back of the recess, a slide upon the carrier adapted to engage a tool, a spring socketed in the carrier and slide respectively, both of said parts being provided with a shoulder against which an end of the spring bears to normally hold the slide raised and means for forcing a slide against a tool to lock it in place in the holder.

6. A tool-holder comprising a head having a transverse recess, an undercut abutment at the forward end of the recess, an inclined carrier at the back of the recess having grooves at its base, a U-shaped slide engaging the carrier and having ribs engaging the grooves and means for forcing the slide against a tool to lock the latter to the holder.

7. The combination with a tool-holder comprising a head having a transverse recess, an undercut abutment at the forward end of the recess, and an inclined slide having a downwardly and rearwardly inclined forward end, of a tool having a base whose forward end is downwardly and forwardly inclined to engage the abutment and whose rear end is downwardly and backwardly inclined for engagement by the slide and means for forcing the slide into engagement therewith.

8. The combination with a tool-holder comprising a head having a transverse recess, an inwardly-inclined undercut abutment at the forward end of the recess and an inclined slide having a downwardly and rearwardly inclined wall at its forward end, of a tool having a base whose forward end is a downwardly and forwardly inclined obtuse angle and whose rear end is a downwardly and rearwardly inclined wall, a spring for normally raising the slide and means for forcing the slide against the tool-base whereby the tool is centered and rigidly locked against movement in any direction.

810,808. MEANS OF CONVERTING CONSTANT OSCILLATORY MOTION INTO RECTILINEAR MOTION. BRUNO SALMEN and GUSTAV WALTHER, Chemnitz, Germany. Filed May 24, 1905. Serial No. 262,661.



Claim.—1. In a device of the class described, the combination of an oscillatory member, elements carried by said member, a movable slide, and means severally engaging said elements with said slide for effecting varying movement of the latter, substantially as set forth.

2. In a device of the class described, the combination of an oscillatory member, elements carried by and spaced at different distances from the axis of said member, a movable slide, and means severally engaging said elements with said slide for effecting varying movement of the latter, substantially as set forth.

3. In a device of the class described, the combination of an oscillatory member, mechanism carried thereby, a movable slide, and means engaging said mechanism with said slide for effecting varying movement of the latter, substantially as set forth.

4. In a device of the class described, the combination of an oscillatory member, elements carried by said member, a reciprocating member, and means engaging said elements with said reciprocating member for varying the degree of reciprocation of the latter, substantially as set forth.

5. In a device of the class described, the combination of an oscillatory member, elements carried by said member, a reciprocating member, and means severally engaging said elements with said reciprocating member for varying the degree of reciprocation of the latter, substantially as set forth.

6. In a device of the class described, the combination of an oscillatory member, elements carried by said member, a reciprocating member, means severally engaging said elements with said reciprocating member for varying the degree of reciprocation of the latter, and means restoring said elements to a normal position, substantially as set forth.

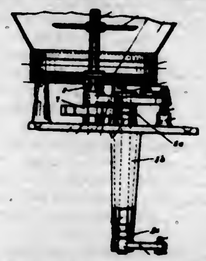
7. In a device of the class described, the combination of a plurality of oscillating members, operating-pins for said members arranged at unequal distances from the axis of said members, a reciprocating member, and means for severally engaging the pins with said member.

8. In a device of the class described, the combination of a plurality of oscillatory members, each provided with a series of operating-pins, reciprocating members, and means for severally engaging said pins with said reciprocating members.

9. In a device of the class described the combination of an oscillating shaft provided with an arm, a series of vertically-displaceable operating-pins mounted in said arms, a slotted reciprocating slide, a selector device for severally engaging said pin with said slide, and a restoring-strip for disengaging said pins from said slide.

10. In a device of the class described, the combination of an oscillating shaft provided with an arm, a series of vertically-displaceable operating-pins, spring-actuated retaining devices for said pins, a slotted reciprocating slide, a selector device for severally engaging said pins with said slide, and a restoring-strip for disengaging said pins from said slide.

810,809. SANDER. SAMUEL T. SIBBOOS and WALTER T. MOORE, Columbus, Ohio. Filed Aug. 15, 1905. Serial No. 274,266.



Claim.—1. A device of the character described, having a cut-off itself, of practically bell-crank formation, adapted to move in an arc, in a vertical plane, and provided with a cleaner entering the discharge-outlet and serving to loosen the contents of the member having said outlet.

2. A device of the character described, having a cut-off itself of practically bell-crank formation, pivoted at one angle or horn to move in an arc, in a vertical plane and effective to close the discharge-outlet, and means for actuating said cut-off.

3. A device of the character described, having a cut-off itself of practically bell-crank formation and pivoted at one angle or horn to move in the plane of the discharge-outlet and to effect the closing thereof, a lever, means for actuating said lever and a pitman effecting connection between said lever and cut-off.

4. A device of the character described, having a cut-off effective to close the discharge-outlet, a lever and means for actuating said lever comprising a pedal or otherwise actuated shaft equipped with an arm, a link between said arm and lever, and a pitman effecting connection between said lever and an arm of said cut-off.

5. A device of the character described, comprising a cut-off effective to close the discharge-outlet, a lever, means for actuating said lever including a pedal or otherwise actuated shaft equipped with a fixed arm, a link between said arm and lever, a pitman effecting connection between said lever and an arm of said cut-off and a spring effective to hold said parts in normal position.

6. A device of the character described, comprising a regulator suitably supported in position upon a hopper-bottom member and arranged to vary the size of the discharge-outlet and its housing equipped with a cut or holding.

7. A device of the character described, comprising a hopper member, a pedal or otherwise actuated shaft having a fixed arm, a cut-off to close the discharge-outlet, an agitator arranged in said hopper member and having its shaft equipped with a ratchet-pinion, a lever connected to said ratchet-equipped shaft and carrying a spring-pressed dog or pawl engaging said ratchet-pinion, a pitman connecting said lever and an arm of said cut-off, a link effecting connection between said lever and arm, and a spring holding the aforesaid parts in normal effective position.

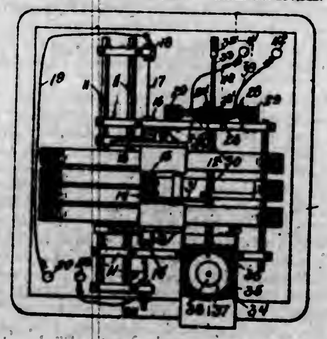
810,810. MAGAZINE. WILLIAM A. SPARKS, Beloit, Kans. Filed Apr. 19, 1905. Serial No. 256,491.

Claim.—1. A device of the class described comprising a tube arranged for the reception of cartridges, said tube being open at its rearward end, means located within the tube for urging cartridges disposed within the tube toward the open end of the latter, and a rod mounted upon the tube and having angular end portions, said rod being arranged for movement to bring its end portions into and out of position for engagement by cartridges within the tube to prevent movement of the latter and being arranged to lie with one of its end portions in position for engagement by cartridges, when its other end portion is out of such position, said rod being also movable to lie with both of its end portions out of such position.

2. A device of the class described comprising a tube arranged for the reception of cartridges and being open at its rearward end, a spring-actuated plunger located within the tube and arranged to urge cartridges toward the rearward end of the tube, spaced ears mounted upon the tube adjacent to the rearward end thereof, said tube having an opening therein forwardly of the ears, a rod mounted in the ears, said rod having angular end portions and being arranged for movement to bring its rearward end portion into and out of position to project over the open end of the tube and to bring its forward end portion into and out of position to extend into the tube through the second-named opening thereof, and means for holding the rod yieldably with its rearward end portion projected over the end of the tube and with its forward end portion disengaged from the opening, the rearward end portion when in its normal position and the forward end portion when in position to extend through the opening being adapted for engagement by cartridges within the tube to prevent movement of the cartridges under the action of the spring-actuated means.

3. A device of the class described comprising a tube open at its rearward end and arranged for the reception of cartridges, a sleeve engaged with the rearward portion of the tube, spaced ears carried by the sleeve, a rod journaled in the ears and having angular end portions, means for moving cartridges through the tube toward the rearward end thereof, said rod being movable to bring its end portions successively into and out of the path of movement of the cartridges and means for holding the rod yieldably with one of its end portions in such position.

810,811. ELECTRORESPONSIVE DEVICE. ELMER A. TREFFINGER, Geneva, Ill. Filed Dec. 17, 1904. Serial No. 237,362.



Claim.—1. In a current-responsive device adapted for actuation by feeble currents, two horseshoe-magnets arranged with opposite poles in proximity to leave therebetween two spaces constituting two strong magnetic fields, a coil having its two sides in said spaces and adapted for connection in a line, means for suspending said coil for oscillation, means for retarding the oscillation of said coil, and working parts associated with the coil to derive their working power from the oscillation of said coil.

2. In a current-responsive device two magnets arranged with opposite poles in separated arrangement in such proximity that they jointly create two magnetic fields, and a coil supported for oscillation with its windings passing between said poles of the magnets, one side of such winding lying in each magnetic field, and said coil being arranged for connection in a circuit.

3. In a current-responsive device, two magnets arranged with opposite poles in separated arrangement in such proximity that they jointly create two magnetic fields, a coil adapted for connection in an electric circuit having its windings passing between the said poles of the magnets, one side lying in each magnetic field, said coil being supported for deflection, and working parts associated with the coil to derive their working power from its oscillation.

4. In a current-responsive device, permanent magnets arranged with the poles of one between the poles of the other, a coil suspended for oscillation with its windings passing down between the proximate poles of the magnets on one side and up between the opposite proximate poles of the magnets on the other side, and working devices connected with the coil for actuation by its oscillation.

5. In a current-responsive device, two magnets arranged with opposite poles in separated arrangement in such proximity that they jointly create two magnetic fields, a coil adapted for connection in an electric circuit having its windings passing between said poles of the magnets, one side of such coil lying in each magnetic field, and said coil being supported for deflection; working parts associated with the coil to derive their working power from its oscillation, and means for retarding the oscillation of the coil, arranged to effect a greater retardation of the movement of the coil in one direction than of its movement in the other direction.

6. In a current-responsive device two magnets arranged with opposite poles in separated arrangement in such proximity that they jointly create two magnetic fields, a coil adapted for connection in an electric circuit having its windings passing between said poles of the magnets, one side of the coil lying in each magnetic field, and said coil being supported for deflection, contact parts comprising a movable member adapted to be operatively moved by deflection of the coil in one direction and a dash-pot operatively associated with the coil arranged to effect a greater retardation of the movement of the coil in the direction to operate the contact than to its movement in the opposite direction.

7. In a current-responsive device, a pair of permanent magnets, arranged with their opposite poles in separated but proximate relation to create two strong magnetic fields, a single coil supported for oscillation with its sides respectively in said fields, said coil being adapted for connection in an electric circuit, and signaling devices operatively connected with said coil for actuation by movement thereof in one direction.

8. A relay comprising two permanent horseshoe-magnets arranged with the poles of one in each separated, proximate relation to the poles of the other as to establish therebetween two strong joint magnetic fields, a coil mounted for deflection with its windings passing between two proximate poles of the magnets one side and between the remaining poles on the other and adapted for connection in a main circuit, contact devices arranged for connection in another circuit, and operative connections between the movable element of said contact devices and the oscillating coil whereby said contact devices are actuated by movement of the coil.

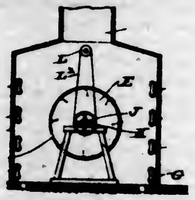
9. A relay comprising a permanent magnet arranged to constitute a magnetic field, a coil supported for oscillation in the field, means for retarding the oscillation of said coil, contact devices including a movable part and operative connection between the movable part of the contact device and the oscillating coil.

10. In combination, a pair of horseshoe-magnets with their opposing poles in proximity and parallelism in a common plane, a single coil adapted for connection in a circuit suspended with its sides passing between the opposite consting poles of the two magnets, a contact device, a dash-pot connected with the contact device, and an operative connection between the coil and said connected parts whereby movement of the coil actuates the contact device and is retarded by the dash-pot.

11. In combination, a pair of magnets with their opposing poles

arranged in proximity to jointly create two strong magnetic fields, a coil adapted for connection in a circuit supported for deflection with its sides respectively in said two fields, a dash-pot having its movable element suspended, a connection between said coil and the suspension of the dash-pot, and working parts associated with the coil to derive their working power from oscillation of the coil.

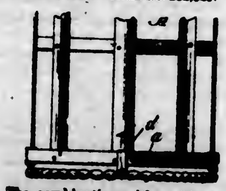
810,312. PROCESS OF AGING DYED FABRICS. PAUL F. VOGEL, St. Louis, Mo., assignor of one-half to Walter W. Calmore, Philadelphia, Pa. Filed May 28, 1903. Serial No. 159,302.



Claim.—1. The herein-described process of aging and fixing colors in dyed fabrics, which consists in subjecting the fabrics to the action of an oxidizable dye, then subjecting the fabrics to the action of air, and continuously rotating the fabrics, the temperature of the air being slowly increased and then decreased to fall to normal when the goods are removed, and finally in aging the fabrics by continuously moving the same through an atmosphere at or below normal temperature.

2. The herein-described process of aging and fixing colors in dyed fabrics which consists in subjecting the fabrics to the action of an oxidizable dye, removing the fabrics, and subjecting the same to the action resulting from their continuous movement in a slowly increasing and decreasing temperature which is allowed to fall to normal when the goods are removed, and finally aging the fabrics in a temperature below normal.

810,313. FRUIT-CARRIER. CHARLES A. WELLMAN, Ottumwa, Iowa. Filed Mar. 27, 1905. Serial No. 252,309.



Claim.—1. The combination with a shipping-case, of a wire frame, a series of rollers loosely mounted thereon, and clasps attached to said wire frame and adapted to engage the case and hold said roller-carrier frame away from the case, substantially as specified.

2. The combination with a shipping-case, of an annular frame formed of wire, a series of rollers thereon, and connections between said case and frame that are adapted to hold said frame and rollers a short distance away from said case, substantially as specified.

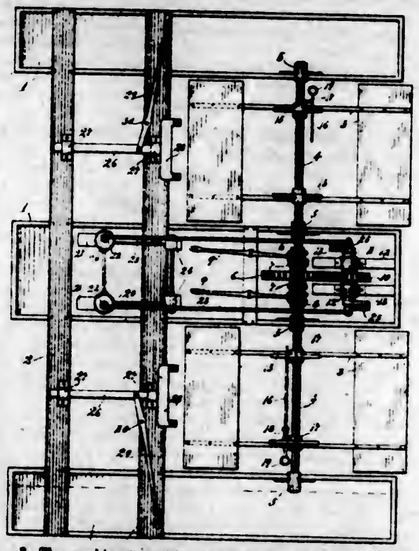
3. The combination with a shipping-case, of a wire frame, a series of rollers mounted thereon, and clasps attached to said wire frame, said clasps being adapted to embrace the lower edge of the case, substantially as specified.

4. The combination with a shipping-case, of a wire frame, a series of rollers mounted thereon, and clasps attached to said wire frame, said clasps being adapted to embrace the lower edge of the case and being provided with shoulders on which the lower edge of the case is adapted to rest, substantially as specified.

810,314. CURRENT-MOTOR. ARTHUR WHEELER and ROBERT B. GROVES, Mile City, Mont. Filed Jan. 28, 1905. Serial No. 243,698.

Claim.—1. The combination with a support, of a water-wheel mounted thereon with its axis above the water-line, said water-wheel having a blade movable pivotally into an inoperative position, and a lock for securing said blade in operative position and for releasing the same, substantially as described.

2. The combination with a support, of a water-wheel mounted thereon, with its axis above the water, said wheel having a pivoted blade movable into an inoperative position, and a stop mounted on said support and movable into the path of the blades of the wheel, substantially as described.



3. The combination with a floating support, of a water-wheel mounted on said support, with its axis above the water, said wheel having a blade movable pivotally into an inoperative position, a lock for securing said blade in an operative position, and for releasing the same, and a stop mounted on said support and movable into the path of the blades of said wheel, to positively stop said wheel when its pivoted blade is released, substantially as described.

4. The combination with a floating support, of a pair of water-wheels mounted thereon, with their shafts in axial alinement, a gear loosely mounted on the adjacent ends of the two shafts, a pair of clutches for connecting said wheels to said gear, arranged to couple said wheels with the blades of the one set ahead of the blades of the other, a gear meshing with the aforesaid gear, a pair of oppositely-projecting cranks connected to said latter gear, a pair of pumps mounted on said support, and connections between said two pumps and said two cranks, substantially as described.

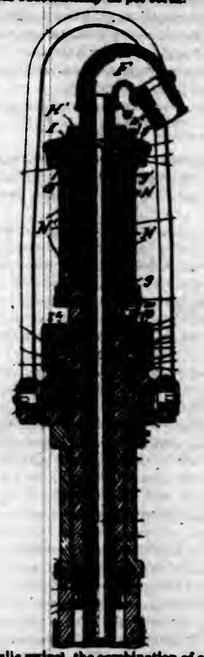
810,315. HYDRAULIC SWIVEL. JAMES A. WIGEN, Jr., Beaumont, Tex. Filed Apr. 3, 1905. Serial No. 253,562.

Claim.—1. In a hydraulic swivel, a tubular, suspended water-stem, having an annular groove in its exterior near its upper end, in combination with a swivel-stem surrounding the same, means for suspending the said swivel-stem, a series of antifriction-balls fitting in the groove of said water-stem to suspend the same and prevent its endwise displacement, a stuffing-box attached to said swivel-stem and grooved at the top to fit the said balls, and a cap screwing down on the said stuffing-box and also grooved to fit the said balls, the grooves in said cap and stuffing-box permitting the said swivel-stem to turn independently on the said water-stem substantially as set forth.

2. In a hydraulic swivel the combination of a water-stem having an annular groove E' with a swivel-stem concentrically arranged thereon, a part screwed on the upper end of the said swivel-stem and having an annular groove G' in its top in proximity to groove E' and a cap H screwed on said part thus grooved in its top, recessed on its under side above the screw-threads to provide an oil-space, having a duct and plug for the supply thereof and further provided with a groove H' in proximity to the grooves before mentioned, means for supporting the said swivel-stem and a series of antifriction-balls, fitting in the three grooves aforesaid to connect the said water-stem to the said swivel-stem and permit swiveling motion but suspend the said water-stem from the said swivel-stem and prevent vertical displacement substantially as set forth.

3. In a hydraulic swivel, the combination of a water-stem and a swivel-stem, concentrically arranged, with means for supporting said water-stem from said swivel-stem and means for suspending said swivel-stem, the latter means including a pair of bearing-plates and interposed antifriction devices and the said plates being provided with overlapping flanges, independent of any other part of the machine, for excluding dust and other foreign matter from said antifriction devices substantially as set forth.

4. In a hydraulic swivel, the combination of a water-stem and a swivel-stem, concentrically arranged, with means for supporting said water-stem from said swivel-stem and means for suspending said swivel-stem, the latter means including a pair of bearing-plates and interposed antifriction devices and the said plates being provided with overlapping flanges, independent of any other part of the machine, for excluding dust and other foreign matter from said antifriction devices substantially as set forth.

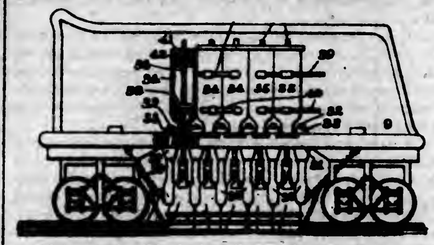


5. In a hydraulic swivel the combination of a water-stem and a swivel-stem, concentrically arranged, of means for supporting said water-stem by said swivel-stem, a ball and trunnion-block for suspending the said swivel-stem, a bearing-plate fixed on said trunnion, an upper bearing-plate turning on the same and having an oil-trough in its upper face, whence a duct extends down to its lower face, a nut threaded on said swivel-stem provided with an oil-supply duct for said trough and bearing against said upper bearing-plate to hold it in position and a series of antifriction devices interposed between the said two bearing-plates, the latter being constructed to leave an oil-space between them about the said antifriction devices and provided with means for excluding dust and other foreign material from the latter substantially as set forth.

6. In a hydraulic swivel, the combination of a water-stem and a swivel-stem, concentrically arranged, with means connecting the stems but allowing the swiveling action, a ball and trunnion-block provided with antifriction devices and bearing-plates, for suspending the said swivel-stem, and a spring-sleeve entered on the said swivel-stem for contact with the lower side of the said trunnion substantially as set forth.

7. In a hydraulic swivel, the combination of a water-stem and a swivel-stem, concentrically arranged, of means for connecting said stems together but allowing swiveling action, a block sleeved on said swivel-stem and provided with means for suspending the latter, a sleeve in contact with the under side of said block, a screw-threaded coupling arranged to hold said sleeve against said block and a depending tubular stem connected to said coupling substantially as set forth.

810,316. EMERGENCY RAIL-BRAKE. POWELL O. ADAMS, Corsicana, Tex. Filed July 6, 1903. Serial No. 164,194.



Claim.—1. A rail-brake for railway-trains comprising a pair of brake-levers mounted on each side of a train and swinging transversely above the rails of the track, means adapting said levers to grasp the rails yieldingly at the point of contact, means for lowering said levers in position for grasping the rails, and means for applying yielding pressure to said levers to cause the same to grasp the rails.

2. In a pneumatic rail-brake the combination of a series of levers mounted transversely the rails of the railway-track and adapted to grasp said rails yieldingly at the point of contact and pneumatic-pressure-regulated pistons connected to said levers whereby power is yieldingly applied to said levers.

3. In a pneumatic rail-brake the combination of a series of pairs of levers, movable fulcrums for said levers, pneumatic-pressure-controlled means for changing the position of the fulcrums, each pair of levers being mounted transversely the rails and adapted to grasp the rails, rail-engaging rollers at the points of contact, and pneumatic-pressure-regulated means connected to said levers for operating the same.

4. In a pneumatic rail-brake the combination of a series of pairs of levers mounted on each side of a train of cars, each pair of levers being arranged transversely above the rail and adapted to grasp the rail yieldingly at the point of contact, means for lowering said levers, and means for applying pneumatic pressure to said levers for operating the same.

5. In a pneumatic rail-brake the combination of a series of levers mounted on each side of a train of cars, a movable fulcrum for each series of levers, pneumatic-pressure-regulated pistons for changing the positions of said fulcrums, said levers being arranged in pairs and each pair having a transverse swinging movement and adapted to grasp the rail, and a pneumatic cylinder provided with a suitable piston connected to each pair of levers.

6. In a pneumatic-pressure rail-brake the combination of a plurality of levers, a series of levers being mounted on each side of a train, said levers being arranged in pairs and each pair having a transverse swinging movement and adapted to grasp the rail, rail-engaging rollers at the points of contact, an adjustable fulcrum for each series of levers, and means for applying pneumatic pressure to said levers for operating the same.

7. In a pneumatic-pressure rail-brake the combination of a plurality of levers, a series of levers being mounted on each side of a train, said levers being arranged in pairs and each pair having a transverse swinging movement, the lower end of each lever constituting a brake-shoe and provided with means for grasping the rail yieldingly at the point of contact, a fulcrum for each series of levers, means for lowering said fulcrums to operative positions, and means for applying pneumatic pressure to said levers for operating the same.

8. In a pneumatic rail-brake the combination of a plurality of levers, a series of levers being mounted on each side of a train, said levers being arranged in pairs and the lower end of each lever constituting a brake-shoe and the brake-shoe being provided with means adapting the same to grasp the rail yieldingly at the point of contact, a fulcrum for each series of levers, means for raising and lowering said fulcrums, and a pneumatic cylinder for each pair of levers provided with a piston connected to each pair of levers.

9. In a pneumatic-pressure rail-brake the combination of a plurality of levers, a series of levers being mounted on each side of a

tuate, said levers being arranged in pairs and each pair having a transverse swinging movement and adapted to grasp the rail, a fulcrum for each series of rails, pneumatic cylinders provided with suitable pistons for raising said fulcrums, and means for operating said levers.

10. In a pneumatic rail-brake the combination of a plurality of levers arranged in pairs and each pair having a transverse swinging movement and adapted to grasp a rail and pneumatic-pressure-regulated pistons connected to said levers, each lever being provided with a bearing-roller.

11. In a pneumatic rail-brake the combination of a plurality of levers arranged in pairs, a fulcrum being mounted on each side of a train, pneumatic cylinders provided with suitable pistons and piston-rods connecting said pistons and said fulcrums, and pneumatic cylinders provided with suitable pistons and piston-rods connecting the last-named pistons to said levers.

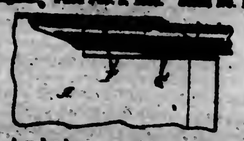
12. In a pneumatic rail-brake the combination of a plurality of levers arranged in pairs, a series of levers being mounted on each side of the train, said levers being arranged in pairs adapted to grasp the rails, brake-cylinders provided with suitable pistons connected to said levers for causing said levers to engage the rails, release-cylinders provided with suitable pistons for disengaging said levers, suitable pipes connected to said cylinders for supplying the same with pneumatic pressure, and means for switching the pressure from the brake-cylinders to the release-cylinders and vice versa.

810,317. DRIVING MECHANISM. ANDREW J. ALLISON, Mount Sylvan, Tex. Filed Dec. 1, 1904. Serial No. 235,971.

Claim.—1. The combination with a driven member, of a rock-lever, a ratchet mechanism connected with the driven member for rotating it, connections between the rock-lever and ratchet mechanism for operating the latter, a toggle-lever connected at one end to the rock-lever and at its opposite end to a fixed support, a treadle and connections between the treadle and a link of the toggle-lever for shifting the links of the lever alternately from one side to the other of their aligning positions when the treadle is oscillated.

2. The combination with a rotatable driven member, of a rock-lever, a pair of ratchet mechanisms connected between the rock-lever and the driven member and adapted to alternately impart motion to the driven member as the lever is rocked, a toggle-lever connected at one end of the rock-lever and pivoted at its opposite end to a fixed support, a treadle and a connection between the treadle and one of the toggle-links for shifting said links from one side to the other of their aligning positions.

810,318. VALVE-BAG. ABRAHAM H. BAUER, Cleveland, Ohio, assignor to Baker Valve Bag Company, Cleveland, Ohio, a Corporation of West Virginia. Filed Feb. 2, 1903. Serial No. 141,562.



Claim.—1. A valve-bag, comprising a body of comparatively inflexible material, with a valve-opening therethrough, and an inner valve extension composed of comparatively flexible material.

3. A valve-bag, comprising a body of material comparatively impervious to air, with a valve-opening therethrough, and an inner valve extension composed of material which permits the air to pass, such material being flexible while the material of the bag is comparatively inflexible.

5. A valve-bag, comprising a bag-body, with a top portion consisting of parts folded together substantially as shown and so as to leave an opening into the bag between such folded parts, and an extension-piece applied to said bag at the inner end of such opening.

6. A valve-bag, comprising a bag proper, with top portions folded and secured together, and a valve extension part inserted in such folds, so as to leave a valve-opening formed partly by the material of the bag and partly by such extension.

7. A valve-bag, comprising a bag proper of paper, with an opening therethrough, and a strengthening-piece of cloth surrounding said opening.

8. A valve-bag, comprising a bag proper of paper, with an opening therethrough, and a strengthening-piece of cloth surrounding said opening, said strengthening-piece projecting inwardly to form a valve extension.

9. A valve-bag, comprising a bag proper of relatively inflexible material, with an opening therethrough, and a strengthening-piece surrounding said opening, said strengthening-piece projecting inwardly to form a valve extension and of flexible material.

10. A valve-bag, comprising a bag proper, with narrow folded-over portions lying one on the other, said portions secured to each other except at one end, so as to leave an opening between them, and a strengthening fabric surrounding such opening.

11. A valve-bag, comprising a bag proper, with narrow folded-over portions lying one on the other, said portions secured to each other except at one end, so as to leave an opening between them, and an inwardly-projecting valve extension surrounding such opening.

12. A valve-bag, comprising a bag proper, with narrow folded-over portions lying one on the other, said portions secured to each other except at one end, so as to leave an opening between them, and an inwardly-projecting strengthening-valve extension portion surrounding the opening, strengthening the same and forming an inner valve portion.

13. A valve-bag, having a square folded top, a filling-opening in said top in position to be closed by one of the folds of said top, and a strengthening-piece adjacent to said fold, as set forth.

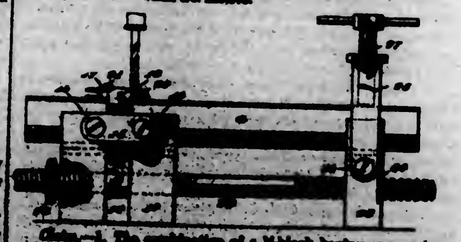
14. A paper valve-bag, having a diamond-folded top, a filling-opening in said top, said opening adjacent to and in position to be closed by one of the primary folds of said top, and a cloth strengthening-piece adjacent to said primary fold, as set forth.

15. A valve-bag, having a square folded top, a lateral filling-opening extending between the folds of said top and in position to be closed by one of said folds, and a cloth strengthening-piece adjacent to the valve fold as set forth.

16. A paper valve-bag, having a diamond-folded top, a lateral filling-opening extending between the folds of said top and in position to be closed by one of the primary folds, and a cloth strengthening-piece adjacent to the valve fold, as set forth.

17. A paper valve-bag, having a diamond-folded top, a lateral filling-opening extending between the folds of said top and in position to be closed by one of the primary folds and a cloth strengthening-piece adjacent to and extending beyond the edge of the valve fold, as set forth.

810,319. V-BLOCK. RICHARD BAARS, New York, N. Y. Filed July 23, 1904. Serial No. 217,270.



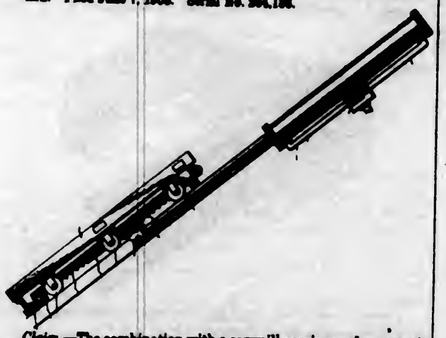
Claim.—1. The combination of a V-block having an opening therethrough, a work-holding device having a corresponding open-

ing therethrough, a rod extending through said openings and provided with threads from one end and annular teeth from the other, a nut on the threaded portion of the rod, and means on the work-holding device for engaging said teeth to hold the V-block and said work-holding device in adjusted relation to each other.

2. The combination of a V-block proper, a horizontal gage-bar, vertically-adjustable means sustaining the gage-bar over the V-block, a horizontally-adjustable tool-holder mounted on the gage-bar, and means for securing the tool-holder to the gage-bar, the latter and the tool-holder having opposite notches therein to admit an operating-tool.

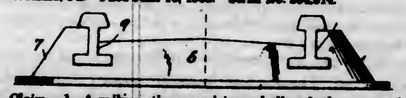
3. The combination of a V-block proper, a horizontal gage-bar, vertically-adjustable means sustaining the gage-bar over the V-block, a horizontally-adjustable tool-holder mounted on the gage-bar, and means for securing the tool-holder to the gage-bar, the tool-holder being U-shaped and fitting the gage-bar transversely thereof, and the latter and the tool-holder having corresponding notches therein to admit a tool.

810,320. SAWMILL-CARRIAGE. CLYDE G. BOSH, Pine Bluff, Ark. Filed June 7, 1905. Serial No. 264,186.



Claim.—The combination with a sawmill-carriage, of a supporting-bracket applied thereto and having downwardly-projecting terminal flanges, a guide-rod supported by said flanges, a head slidably mounted on the guide-rod and provided with an angular face to engage the bracket to hold said head from rotation, a regulating-plate on the guide-rod adjacent to one of said flanges, springs upon the guide-rod between the head and the other flange and the head and regulating-plate, means for imparting motion to the head to reciprocate the carriage, and means for adjusting the regulating-plate, the construction being such that the parts of the device are supported by said bracket, whereby the device is adapted for attachment to any ordinary sawmill-carriage.

810,321. METALLIC RAILROAD-TIE. SAMUEL T. CARROLL, Crothers, Pa. Filed June 10, 1905. Serial No. 264,614.

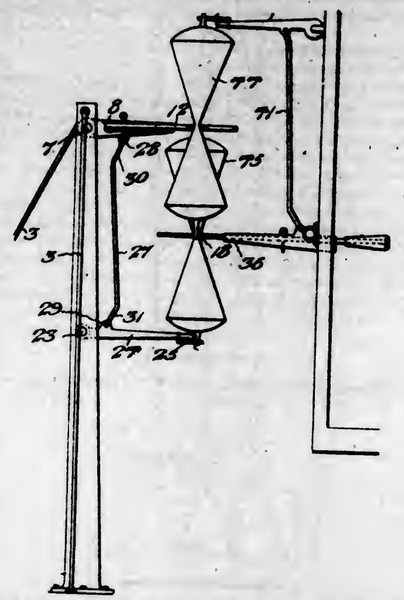


Claim.—1. A railway-tie comprising a hollow body open at its top and bottom and including spaced downwardly-diverging sides and connected downwardly-diverging end portions that extend above the sides, and a base-flange extending continuously about the sides and ends of the body portion, said body portion having rail-receiving sockets opening through the angles between the sides and the upwardly-extending portions of the ends.

2. A railway-tie comprising laterally-spaced sides that diverge downwardly and connected ends that diverge downwardly and project above the sides, there being rail-receiving sockets opening through the angles between the sides and the upwardly-projecting portions of the ends.

810,322. RAIL-BAG CATCHER. JOHN F. CHERRY, Louisville, Ky., assignor of two-fifths to Joseph Schaefer and two-fifths to John J. Sullivan, Louisville, Ky. Filed July 5, 1905. Serial No. 268,183.

Claim.—1. In a device of the class described, a support, a bearing member pivotally connected therewith and having an opening and a pair of oppositely-disposed recesses communicating with said opening, a bag-receiving member having a shank journaled for rotation in and for movement longitudinally of the opening and an angular portion adapted to seat in either of the recesses, and a coupling-pin engaged through the bearing member and shank for fixing said shank against longitudinal movement.



2. In a device of the class described, a support, a bearing member pivotally connected therewith, a bag-engaging member journaled for rotation in the bearing member, interlocking connections between the members to prevent rotation of the engaging member, the latter being adapted for longitudinal movement to effect its release, and a coupling-pin entered through and for fixing the members against relative longitudinal movement.

3. In a device of the class described, a support, a bearing member pivotally connected therewith and provided with a recess, a bag-engaging member rotatively engaged with the bearing member and having a portion designed to seat in said recess, said engaging member being longitudinally movable relative to the bearing member for seating said portion in or unseating it from the recess, and a coupling-pin for fixing the parts against relative longitudinal movement.

810,323. SWITCH-OPERATING DEVICE. WILLIAM A. GREEN, Houston, Tex. Filed July 12, 1905. Serial No. 269,269.

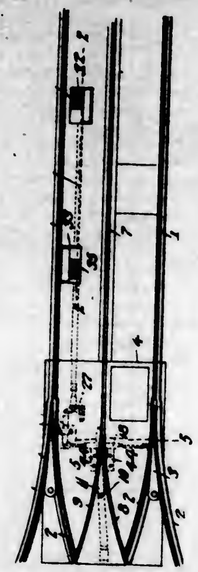
Claim.—1. In a switch-operating mechanism, a plurality of switches, a longitudinally-movable traction element, a pair of reversely-movable depressible shoes connected with and for moving the element respectively in reverse directions, and operative connections between the element and switches for operating and imparting simultaneous movement to the latter.

2. In a switch-operating mechanism, a plurality of switches operatively connected for simultaneous movement, a longitudinally-movable traction element, a pair of reversely-disposed bell-crank levers connected with said element, reversely-movable depressible shoes connected respectively with and for operating the levers to move the element in reverse direction, and operative connections between the element and switches for throwing the latter in opposite directions upon depression of the respective shoes.

3. In a switch-operating mechanism, a plurality of switches, a system of levers connecting the switches for simultaneous movement, a longitudinally-movable element, a pair of depressible shoes operatively connected with the element for moving the same in reverse directions, and operative connections between the element and one of the levers for actuating the latter to move the switches.

4. In a switch-operating mechanism, a plurality of underground

casings, tubular sections connecting the casings, a longitudinally-movable element extended between the casings within the tubular sections, reversely-disposed bell-crank levers housed respectively in said casings and connected for moving the element in reverse directions, a lever operated by the element, and a switch connected for operation by the lever.



810,324. EGG-CARRIER. NELSON H. CLARK and ROBERT L. CLARK, Mannsville, N. Y. Filed Jan. 6, 1905. Serial No. 240,834.

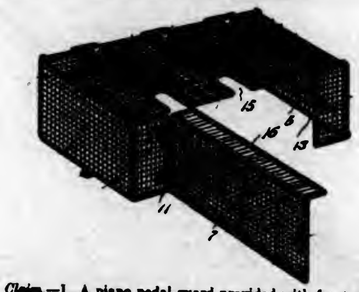
Claim.—1. A package adapted for the transportation of fragile articles and comprising a body-section having recesses in the upper edges of opposite sides, the recesses being at or near the central portion of the sides, partitions in the body-section dividing the body into pockets, a tray-cover for the body-section fitting within the same, the top of said cover when in position being below the plane of the upper edge of the body-section, and a bail having its side members pivoted to the side portions of the body-section at one side of the center and adjacent to the bottom edges of said sides, the said bail being adapted to engage the recesses in the sides of the body-section and bear on the top surface of the tray-cover to hold the tray-cover in position, as described.

2. A package consisting of a body-section having opposing recesses in the upper edges of opposing surfaces, a bail having the terminal portions of its side members pivotally attached to the side portions of the body at one side of the center thereof, the upper section of which bail in its locking position is arranged to enter the said recesses, supports within the body, and an inverted-tray-shaped cover for the body, engaging with the said supports, the top of the cover when in position being below the plane of the upper edge of the body-section and adapted to be held in position by the said bail, for the purpose described.

3. The combination with the body of a receptacle having recesses in the upper edges on opposite sides, a bail pivotally attached to the body, extending upwardly from its pivotal point and across the upper portion of the body, the said bail at the intersection of its members being provided with upwardly-extending loops, the members of which loops, in the locking position of the bail are located at the outer and inner surfaces of the said side members of the body of the receptacle at the aforesaid recesses therein, partitions dividing the said body of the receptacle into a series of pockets, the ends of which partitions are beveled downwardly and outwardly, and an inverted tray-cover adapted to be held in engagement with the said partitions by means of the said bail, the marginal portions of which tray-cover enter the spaces between the ends of the partitions and the adjacent surfaces of the body of the receptacle, as set forth.

4. A package consisting of a body-section having opposing recesses in the upper edges of opposite sides, a bail having side members pivotally attached to the sides of the body-section, and an upper or connecting member extending across the upper portion of the body, the bail at the intersection of the upper and side members being provided with upwardly-extending loops, the members of said loops, when the bail is in locking position, extending down at the inner and outer surfaces of the sides of the body at the said recesses, and a separable tray-cover for the body-section adapted to be held in place by the bail, as set forth.

810,325. PIANO PEDAL-GUARD. MARGARET B. CLEMENTS, Eastman, Ga. Filed July 20, 1905. Serial No. 271,617.



Claim.—1. A piano pedal-guard provided with front and rear sets of slots, and means for closing either set of slots.

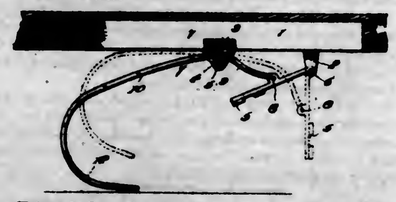
2. A piano pedal-guard provided with sets of openings, and reversible closures for closing either set of openings.

3. A piano pedal-guard provided with openings for the passage of a pedal-rod located at different distances from the front wall of the piano, and a reversible closure for closing either opening.

4. A piano pedal-guard provided with an open front and a doorway in its rear, and formed in the front and rear edges of its top wall with slots, a hinged door for closing said doorway, said door being provided with an extension to partly close the rear slots, and reversible closures for closing either the front or the rear slots at will.

5. A piano pedal-guard comprising an oblong rectangular casing formed of a wire frame having a body of woven material, said casing being provided with an open front side and having a doorway in its rear side, the top wall of the casing being provided in its front and rear edges with slots, a hinged door at the rear side adapted to close said doorway and provided with a projection to partially close the rear slots, and pivoted closures upon the top wall reversible to close either set of slots.

810,326. CAR-FENDER. JOSEPH B. COMMON, Liverpool, England, assignor to Thomas Hurtland, New York, N. Y. Filed Sept. 19, 1905. Serial No. 279,289.



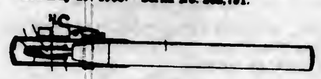
Claim.—1. In a safety device for cars, a tray or fender designed to be moved vertically toward and away from a track, a vertically-suspended gate designed to be swung in the arc of a circle, a connection between said tray and said gate having a curved or cam-shaped portion, a rigid support for said connection through which the latter is movable, whereby the longitudinal movement of said connection consequent upon the swing of the gate will effect the movement of said tray.

2. In a safety device for cars, a tray or fender, a gate, brackets designed to be rigidly secured to a car-frame, rods connecting the tray with the gate, said rods being longitudinally curved and movable in said brackets, whereby said tray is caused to move vertically upon the swinging of said gate.

3. In a safety device for cars, a tray or fender, a gate, a rigid support secured to a car-frame, a rod connecting the tray with the gate, said rod being longitudinally movable in said support and having an upwardly-curved portion normally intermediate the support and the gate, and a relatively straight portion intermediate the support and the tray whereby in the normal positions of the parts the relatively straight portion is in engagement with the support and upon swinging the gate the rod moves rearwardly and its curved portion engages the support, for the purpose stated.

4. In a safety device for cars, a tray or scoop, a gate, supports designed to be secured to a car-frame and to which said gate is pivoted, brackets also designed to be secured to the car-frame, and rods pivoted to said gate, movable longitudinally in said brackets and forming the side bars of said tray, said rods being curved longitudinally, for the purpose stated.

810,327. FOUNTAIN-PEN. MARTIN R. CROSSMAN, Boston, Mass. Filed May 29, 1905. Serial No. 262,781.



Claim.—In a fountain-pen, a holder, a pen-point, a cap to fit over the holder and pen-point, an antisweating-cap of a size to be received within first-mentioned cap and of a shape to fit tightly over the pen-point and means carried by the pen to sustain said antisweating-cap when the latter is not in use.

810,328. CATTLE-GUARD. ANDREW DEVAN, Missoula, Mont. Filed May 29, 1905. Serial No. 262,543.

Claim.—1. A cattle-guard consisting of a pair of members extending in the same direction and forming a pocket, said members being arranged between a pair of rail-ties, and said members further having the upper edges thereof serrated.

2. A cattle-guard consisting of a front and a rear member extending at an inclination and suitably connected together, thereby forming a pocket, said members adapted to be interposed between a pair of rail-ties and each of said members having its upper edge serrated.

3. A cattle-guard comprising a front and a rear member extending at an inclination, one of said members secured to a tie and the other of said members being resilient, said members suitably connected together at their lower ends to form a pocket.

4. A cattle-guard comprising a front and rear member extending at an inclination, one of said members secured to a tie and the other of said members being resilient, said members suitably connected together at their lower ends to form a pocket, and each of said members having its upper edge serrated.

5. A cattle-guard adapted to be interposed between a pair of ties and comprising a fixed and a resilient inclined member, said movable member projecting away from one of the ties and the other of said members fixed to the other of said ties.

6. A cattle-guard adapted to be interposed between a pair of ties and comprising a fixed and a resilient member suitably connected together at their lower ends and spaced apart to form a pocket, one of said members fixed to one of said ties, said members having a serrated edge.

7. The combination with a railway-tie having an inclined bearing-surface, of a cattle-guard comprising a front and a rear member extending at an inclination and having serrated edges, said members suitably spaced apart to form a pocket, and one of said members resting upon said bearing-surface and fixed to said tie.

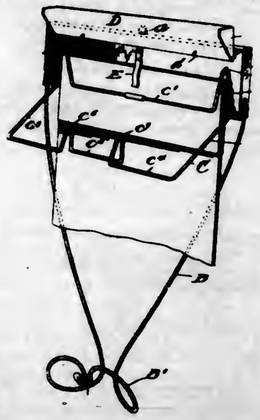
8. The combination with a railway-tie having an inclined bearing-surface, of a cattle-guard comprising a front and a rear member extending at an inclination and having serrated edges, said members suitably spaced apart to form a pocket, and one of said members resting upon said bearing-surface and fixed to said tie, said fixed member having a portion thereof extending at a greater inclination than the remaining portion thereof.

9. A cattle-guard consisting of a piece of sheet-metal material bent to form a front and rear inclined member terminating at their lower ends in a body portion adapted to rest upon the track-bed, one of said members being of less length than the other of said members and both of said members having their top edges serrated, said members being suitably spaced apart to form a pocket.

10. A cattle-guard consisting of a piece of sheet-metal material bent to form front and rear inclined members terminating at their lower ends in a body portion adapted to rest upon the track-bed, one of said members being of less length than the other of said members and both of said members having their top edges serrated, said members being suitably spaced apart to form a pocket, combined with a railway-tie having an inclined bearing-surface for said longer member, and means for securing said elongated member to the said tie.

11. A cattle-guard comprising a plurality of sections and each consisting of a piece of sheet-metal material bent to form front and rear inclined members terminating at their lower ends in a body portion adapted to rest upon the track-bed, one of said members being of less length than the other of said members and both of said members having their top edges serrated, said members being suitably spaced apart to form a pocket, combined with a railway-tie having an inclined bearing-surface for said longer member, and means for securing said elongated member to the said tie.

810,329. DUST AND SCRAP BAG AND HOLDER. EMILY DYETT, New York, N. Y. Filed Dec. 2, 1904. Serial No. 235,274.



Claim.—1. In a bag-holding device, the combination with the supporting-frame, comprising the rigid back provided with the means for supporting the same and a wire frame connected to said back and provided at its lower end with a supporting-loop for receiving the bottom of the bag, said back being provided with means for engaging the inner portion of the mouth of the bag to support the same, of a rigid open frame connected to said back adapted to surround the mouth of the bag, and having a front cross-piece forward of said back, provided with portions for engaging the outer and also the inner side of the front portion of the mouth of the bag for holding the bag in open position, substantially as described.

2. In a bag-holding device, the combination with the vertical supporting-frame provided at its lower end with a support for the bottom of the bag and having at its upper end a vertically-disposed spring-clip, of an open rectangular frame hinged to the upper part of the main frame and provided with means for maintaining it in an angle to the main frame, said open frame being adapted to surround a bag and having an outer cross-piece at a distance from the main frame provided with separated portions for engaging the inner and outer sides of the front portion of the mouth of the bag and a cover hinged to said main frame above the said open frame and adapted to be supported thereby, substantially as described.

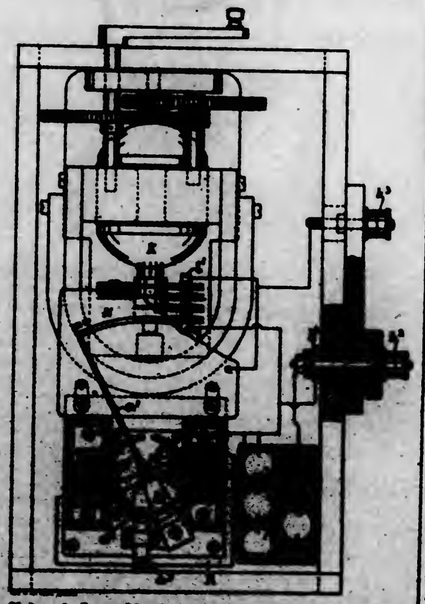
3. In a bag-holding device, the combination with the supporting-frame comprising the rigid back and a wire frame connected thereto having the ends of the wire connected to said back and the central portion formed into a supporting-loop for receiving the bot-

tom of the bag, an open frame formed of wire, pivotally connected to said hook, and provided with a rear clamping member for engaging said hook below the pivotal connection therewith, and having its front part provided with a clip to receive the front part of the mouth of the bag, and a cover pivoted to the hook and adapted to engage said pivoted frame when in closed position and be supported thereby, substantially as described.

4. In a bag-holding device, the combination with the supporting-frame comprising the rigid hook provided with means for supporting it in a vertical position and a wire frame connected to said hook and provided at its lower end with outwardly and upwardly bent portions for supporting the bottom of the bag, a spring-clip secured centrally to the rigid hook adjacent to its upper end, a rigid rectangular open frame pivotally connected to said hook and provided with a downwardly-extending clamping member adjacent to said hook for maintaining said open frame at an angle to said hook, said open frame being constructed to surround the mouth of the bag and having a front piece parallel to and at a distance from said hook provided with separate portions for engaging the inner and outer sides of the front portion of the mouth of the bag and a cover hinged to said hook above said open frame and adapted to be supported thereby, substantially as described.

5. In a bag-holding device, the combination with a supporting-frame comprising the hook, and a wire frame having its ends secured to said hook, and its central portion bent into a supporting-loop to support a bag to be filled, the upwardly-bent portion of said loop being provided with a supporting-hook, of an open frame pivoted to said hook and provided with a clamping portion to engage said hook and having its front portion provided with a vertically-disposed clip to engage a portion of the mouth of the bag, and a cover pivoted to said hook and adapted to engage and be supported by said pivoted frame, substantially as described.

810,330. APPARATUS FOR MEASURING ELECTRIC RESISTANCES. SIDNEY EVERSHED, Ilkeston, England, assignor to Messrs. Evershed and Vignoles Limited, Chiswick, England, a Corporation. Filed Feb. 27, 1904. Serial No. 195,611.



Claim.—1. In combination, a generator of electric current; an electrometer in close proximity to the generator having a rotatable index-pointer and equatorial plate thereon, in stable equilibrium throughout its range as regards gravitational or torsional forces; four quick-quadrants mounted electrically in two pairs, grouped about the rotatable index-pointer; electrically-guarded insulations for the connection between one pair of quadrants and an external terminal; an electrical resistance connecting the two pairs of quadrants; and adapted to cause a difference of potential between them and a portable box inclosing the whole apparatus.

2. In combination, a generator of electric current; an electrometer in close proximity to the generator, having a rotatable index-pointer in stable equilibrium throughout its range as regards gravitational or torsional forces; electrically-guarded insulations to avoid leakage; and a portable box inclosing the whole apparatus.

3. In combination, a generator of electric current; an electrometer in close proximity to the generator, having a rotatable index-pointer in stable equilibrium throughout its range as regards gravitational or torsional forces; two pairs of quadrants grouped about the rotatable index-pointer; insulations under one pair of quadrants, about an external terminal, and under the resistances; guard metal plates adjoining said insulations; connections to the said guard-plates from a terminal of the current-generator to avoid leakage; and a portable box inclosing the whole apparatus.

4. In combination, a generator of electric current; an electrometer in close proximity to the generator, having a rotatable index-pointer in stable equilibrium throughout its range as regards gravitational or torsional forces; a sector metallic plate upon the index-pointer axis, a magnet acting upon the said sector-plate as a magnetic brake; and a dial-plate with the framework carrying the movable system metallically connected together and to one terminal of the electric-current generator.

810,331. STOPPER RETAINING AND EXTRACTING DEVICE. WILLIAM L. GALLAGHER, Point Rayes Station, Cal. Filed Sept. 13, 1905. Serial No. 278,282.

Claim.—A vessel having a neck, a stopper adapted to be seated in the latter and provided with a transverse opening, a flexible element threaded through said opening and bent in reverse directions across the top of the stopper and thence downward to form depending portions terminating at their lower ends in loops, the element being thereafter wrapped around the neck to present a pair of independent superposed coils terminating in loops having interlocking engagement with the loops on the arms, the terminals of the element being finally crossed and twisted.

810,332. SHOULDER-FORM. ALEXANDER H. GRAHAM, New York, N. Y. Filed June 2, 1905. Serial No. 263,469.

Claim.—1. As a new article of manufacture, a shoulder-form for garments comprising a fabric sheet having a shoulder and curved lengthwise and crosswise, and a flattened neck end, the contour of the form being in compound curves.

2. As a new article of manufacture, a shoulder-form for garments comprising a fabric sheet having a flattened neck end, a padded shoulder and curved lengthwise and crosswise and elevated above the neck end, and a series of apertures from the neck end to the pads, the whole contour of the form being in compound curves, substantially as shown and described.

810,333. SHOULDER AND SLEEVE FORM. ALEXANDER H. GRAHAM, New York, N. Y. Filed June 10, 1905. Serial No. 264,888.

Claim.—1. As a new article of manufacture, a shoulder-form for garments comprising a tapering portion adapted to extend into the shoulder of the garment, and a wing extending upwardly and outwardly from and at an angle to said portion.

2. As a new article of manufacture, a shoulder-form for garments, comprising a shoulder portion having a tapering arm adapted to extend the length of the shoulder, and a wing extending throughout the outer edge of the shoulder portion and projecting from the latter upwardly and outwardly in shoulder shape.

810,334. BOTTLE-SEAL. ANDREW L. GREEN, Lake City, Fla. Filed Aug. 5, 1905. Serial No. 272,502.

Claim.—1. The combination with a receptacle having the edge of its mouth formed with a notch, of a cap arranged for threaded connection with the receptacle and provided with a key to engage said notch to prevent movement of the cap in one direction.

2. The combination with a receptacle having its mouth edge formed with a notch having a vertical wall, of a cap adapted for threaded connection with the receptacle, and a key centered intermediately of the cap and adapted to rest in the notch and against said vertical wall in the cap is in sealing position on the receptacle.

3. A bottle having a threaded neck, the free edge of said neck being formed with a notch, and a cap adapted for connection with the threaded neck, said cap being provided with an interior key to engage the notch with the bottle-neck when the cap has been moved to the limit of its sealing position.

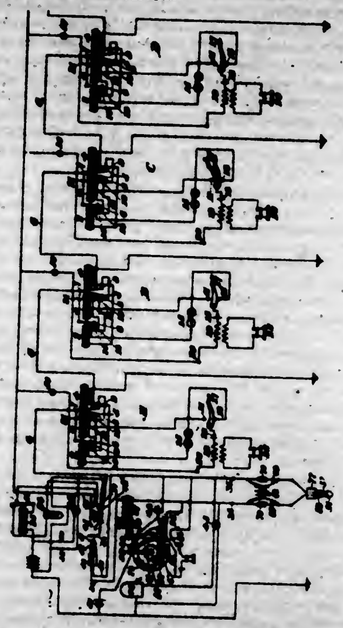
4. A bottle having a threaded neck, the free edge of said neck being formed with a notch having a vertical wall, and an inclined bottom, said inclined bottom extending in the direction of the operative projection of the threads, a cap arranged for threaded connection with the bottle, and a key centered to the cap and adapted to engage said notch when the cap has been entered to the limit of its sealing position on the bottom of the cap on its sealing-neck.

5. A bottle-cap comprising a disk and a circumferentially-depending flange, and a key arranged laterally and intermedially of the cap, said key projecting from the disk portion of the cap adjacent the depending flange.

6. A sealing-cap comprising a disk portion and an integrally-depending circumferential flange, and a key secured to the under side of the disk portion and arranged radially thereof, said key having a projecting portion spaced from the disk adjacent the circumferential flange.

810,335. SELF-ADJUSTING SAFETY-LOCK. FRANK S. HOLT and JAMES P. STOUT, Wheeling, W. Va. Filed Sept. 22, 1905. Serial No. 279,284.

Claim.—1. In a selective party-line system, the combination with a battery, a continuous metallic line, normally open connections leading from said line to a series of stations, automatic switching mechanism at each station, and mechanism arranged to complete the circuit through said connection at any station and then cut out the battery from the continuous line.



2. A central station having a local signal-circuit, a continuous metallic line extending from the central station, connections leading from said line to a series of stations, automatic switching mechanism at each station, mechanism arranged to complete the circuit at any station, a battery normally included in circuit with the continuous line, and means adapted to cut out the battery from the continuous line and to connect it to a local signal-circuit.

3. A central station, a continuous metallic line extending therefrom, a second line extending therefrom and broken at a series of stations, automatic switch mechanism for bridging up the broken line successively through each station, automatic switch mechanism at each station, including a polarized magnet and arranged to connect the stations to the metallic circuit, and means at central station for sending a reverse current to actuate the polarized switch system at any desired station; substantially as described.

4. A central station having a step-by-step indicator, a continuous metallic line extending from the indicator, a second broken metallic line extending from the indicator and having a station at each break, a ground-circuit at each station, automatic switch mechanism for bridging up the broken line successively through each station, and automatic switch mechanism at each station, including a polarized magnet, and arranged to break the ground-circuit and connect the station to the metallic circuit and mechanism at central station for sending a reverse current to actuate the polarized switch system at any desired station; substantially as described.

5. In a telephone system the combination with a central exchange, of lines extending therefrom to a plurality of subscribers, telephonic apparatus at each subscriber, a polarized relay at each subscriber for controlling the corresponding telephonic apparatus, a non-polarized relay at each subscriber for controlling the continuity of the circuit through a pair of said lines, current-flow in one direction from the central exchange causing operation of the non-polarized relays at the subscribers whereby the line controlled thereby is made continuous to the desired subscriber, and means upon current-flow in another direction from the central exchange for sending the telephonic apparatus at the desired subscriber to be connected with the lines upon operation of the polarized relay.

6. In a telephone system the combination with a central ex-

change, of lines extending therefrom to a plurality of party-substations, signaling apparatus at each substation, a polarized relay at each substation controlling the connection of said signaling apparatus with the line, one of said lines being normally broken at each substation, a non-polarized relay at each substation for controlling the continuity of the normally broken line, a source of current at the central exchange, current-flow from said source through the lines in one direction causing successive actuation of the non-polarized relays at the substations whereby the normally broken line may be rendered continuous to a desired substation, means upon current-flow from said source through the lines in the opposite direction causing the actuation of the polarized relay at the desired substation whereby the signaling apparatus at said substation is connected with the lines, and means at the central exchange for sending signaling-current through the lines whereby the signaling apparatus at the desired substation may be selectively actuated.

7. In a telephone system the combination with a central exchange, of lines extending therefrom to a plurality of substations, normally disconnected sections of line connecting the successive substations, a relay at each substation adapted upon actuation to close the line-sections terminating thereat, and means upon current impulse in one direction from the central exchange for causing actuation of the successive relays at the substations whereby the disconnected sections may be connected together to offer a continuous line to a desired substation, signaling apparatus at each substation normally disconnected from the lines, and a second relay at each substation controlling the connection of the signaling apparatus with the line, current impulses from the central exchange in an opposite direction causing actuation of only the second relay at the desired substation whereby the signaling apparatus at its substation is connected with the central exchange exclusive of the signaling apparatus at other substations.

8. In a telephone system the combination with a central exchange, of telephone-lines extending therefrom to a plurality of party-substations, one of said lines being normally discontinuous at each substation, a relay at each substation for controlling the continuity thereat of the normally broken line, signaling apparatus at each substation, a second relay for controlling the connection of said signaling apparatus with the lines and with the central exchange, means at the central exchange for sending current impulse of one polarity into the lines and successively serially through the two relays at each substation until the desired substation is reached, these current impulses causing the actuation of only the first relays whereby said relays are disconnected from circuit and the normally broken line rendered continuous to the desired substation, means at the central exchange for sending impulses into the lines of opposite polarity to cause current-flow of opposite polarity serially through the two relays at the desired substation, the second relay being responsive to this current-flow of opposite polarity whereby the signaling apparatus at the desired substation only is operatively connected with the lines.

9. In a telephone system the combination with a central exchange, of telephone-lines extending therefrom to a plurality of party-substations, one of said lines being normally broken at each substation, a non-polarized relay at each substation adapted upon actuation to close the normally broken line thereat, signaling apparatus at each substation normally disconnected from the lines, a polarized relay at each substation controlling the connection of said signaling apparatus with the lines, said relays being normally connected serially in circuit with the preceding section of the normally broken line and with the armature of the non-polarized relay, means at the central exchange for sending current impulses of one polarity through a normally broken line, whereby the relays at each substation are successively connected in circuit, said current-flow of one polarity causing actuation only of the non-polarized relay whereby the normally broken line is rendered continuous to the desired substation, means at the central exchange, when the desired substation is reached, for sending a current of opposite polarity over the built-up line, whereby both relays at the desired substation are actuated and whereby the signaling apparatus at the desired substation is connected with the central exchange upon actuation of the polarized relay, and means at the central exchange for sending a signaling-current through the lines to actuate the selected substation signaling apparatus.

10. In a telephone system the combination with a central exchange, of telephone-lines extending therefrom to a plurality of party-substations, one of said lines being normally broken at each substation, a relay at each substation controlling the continuity of the normally broken line thereat, signaling apparatus at each substation, a second relay controlling the connection of said signaling apparatus with the line, said first and second relays being connected serially in circuit, means upon current-flow in one direction from the central exchange into the first section of the normally broken line for causing current-flow through the first and second relays at the first substation, means for allowing actuation of only the first relay, whereby the first section is directly connected with the following section leading to the second substation, whereby the normally broken line may be rendered continuous to any desired substation, means at the central exchange for sending current impulses of opposite polarity through the built-up line and serially through the first and second relays at the desired substation, said second relay being responsive to the current of opposite polarity, whereby the signaling apparatus at the desired substation is connected with the lines and with the central exchange.

11. In a telephone system the combination with a central exchange, of lines extending therefrom to a plurality of substations, one of said lines being normally broken at each substation, a relay at each substation controlling the continuity of the normally broken line thereat, signaling apparatus at each substation, a second relay controlling the connection of said signaling apparatus with the line, said first and second relays being connected serially in circuit, means upon current-flow in one direction from the central exchange into the first section of the normally broken line for causing current-flow through the first and second relays at the first substation, means for allowing actuation of only the first relay, whereby the first section is directly connected with the following section leading to the second substation, whereby the normally broken line may be rendered continuous to any desired substation, means at the central exchange for sending current impulses of opposite polarity through the built-up line and serially through the first and second relays at the desired substation, said second relay being responsive to the current of opposite polarity, whereby the signaling apparatus at the desired substation is connected with the lines and with the central exchange, and a restoring-relay at each substation adapted upon actuation from the central exchange to restore the switch mechanisms of the first and second relays to their normal positions.

12. In a telephone system the combination with a central exchange, of lines extending therefrom to a plurality of substations, one of said lines being normally broken at each substation, a relay at each substation controlling the continuity of the normally broken line thereat, signaling apparatus at each substation, a second relay controlling the connection of said signaling apparatus with the line, said first and second relays being connected serially in circuit, means upon current-flow in one direction from the central exchange into the first section of the normally broken line for causing current-flow through the first and second relays at the first substation, means for allowing actuation of only the first relay, whereby the first section is directly connected with the following section leading to the second substation, whereby the normally broken line may be rendered continuous to any desired substation, means at the central exchange for sending current impulses of opposite polarity through the built-up line and serially through the first and second relays at the desired substation, said second relay being responsive to the current of opposite polarity, whereby the signaling apparatus at the desired substation is connected with the lines and with the central exchange, and a restoring-relay at each substation adapted upon actuation to restore the other relays and circuits to their normal positions.

13. In a telephone system the combination with a central exchange, of lines extending therefrom to a plurality of party-substations, signaling apparatus at each substation, a relay at each substation controlling the connection of the signaling apparatus with the lines, one of said lines being normally broken at each substation, a second relay at each substation adapted upon actuation to close the broken line thereat, whereby the broken line may be rendered continuous to any desired substation, a restoring-relay at each substation adapted upon actuation to restore the switch mechanisms of the other relays to their normal positions.

14. In a telephone system the combination with a central exchange, of lines extending therefrom to a plurality of party-substations, one of said lines being normally broken at each substation, a relay at each substation controlling the continuity of the normally broken line thereat, signaling apparatus at each substation, a second relay controlling the connection of said signaling apparatus with the line, said first and second relays being connected serially in circuit, means upon current-flow in one direction from the central exchange into the first section of the normally broken line for causing current-flow through the first and second relays at the first substation, means for allowing actuation of only the first relay, whereby the first section is directly connected with the following section leading to the second substation, whereby the normally broken line may be rendered continuous to any desired substation, means at the central exchange for sending current impulses of opposite polarity through the built-up line and serially through the first and second relays at the desired substation, said second relay being responsive to the current of opposite polarity, whereby the signaling apparatus at the desired substation is connected with the lines and with the central exchange, and a restoring-relay at each substation adapted upon actuation from the central exchange to restore the switch mechanisms of the first and second relays to their normal positions.

15. In a telephone system the combination with a central exchange, of lines extending therefrom to a plurality of party-substations, telephonic apparatus at each substation, a source of current at the central exchange, an indicator-relay at the central exchange, actuation of the telephonic apparatus at any substation causing closure of a circuit through said source and said relay, actuation of said relay causing disconnection of said source from the lines and connection of said source to a local circuit including an indicating-signal.

16. In a telephone system the combination with a central exchange, of lines extending therefrom to a plurality of party-substations, telephonic apparatus at each substation normally disconnected from the line, a relay at each substation controlling the action of said telephonic apparatus with the line, a source of current and indicating mechanism at the central exchange, actuation of the telephonic apparatus at a calling-substation causing the closure of a circuit through said relay, said source of current and said signaling apparatus, whereby the telephonic apparatus is connected in circuit by the relay, and means upon actuation of the indicating apparatus for causing disconnection of said source from the lines thereby to prevent connection of the telephonic apparatus with the line at other substations.

17. In a telephone system the combination with a central exchange, of lines extending therefrom to a plurality of party-substations, telephonic apparatus at each substation normally disconnected from circuit, a relay at each substation controlling the connection of said telephonic apparatus with the lines, a source of current and a relay at the central exchange, means upon actuation of the telephonic apparatus at one substation for closing a circuit through said source of current to said substation-relay and central-exchange relay, actuation of the substation-relay causing connection of the telephonic apparatus with the line and with the central exchange, and actuation of said central-exchange relay causing disconnection thereby of said source from the line and connection of said source in a local circuit with an indicating-signal, the telephonic apparatus at other substations being prevented from connection with the lines upon disconnection therefrom of said source.

18. The combination with a central station, of a line running from said central station broken at a series of substations, electromagnetic mechanism controlled from the central station adapted to build up a non-inductive circuit through said broken line to any desired substation, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, and electromagnetic mechanism controlled from said central station adapted to connect the said second line with the signaling apparatus at any of said substations, substantially as described.

19. The combination with a central station, of a line running from said central station broken at a series of substations, electromagnetic mechanism controlled from the central station adapted to build up a non-inductive circuit through said broken line to any desired substation, other electromagnetic mechanism controlled from said central station adapted to break said electric circuit at said substations, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, and electromagnetic mechanism controlled from said central station adapted to connect the said second line with the signaling apparatus at any of said substations, substantially as described.

20. In combination, a central station, three lines leading therefrom to a series of substations, one of said lines being normally broken at each substation, electromagnetic selective apparatus at each of said substations adapted to be connected in series with one of said lines and adapted to be connected in multiple with either of the other two lines, and electromagnetic mechanism at each of said substations controlled from the central station adapted to automatically connect said selective apparatus in series with the broken line, and adapted to automatically disconnect the multiple connections of said selective apparatus with one of the other two lines, substantially as described.

21. In combination, a central station, three lines leading therefrom to a series of substations, one of said lines being normally broken at each substation, electromagnetic selective apparatus at each of said substations adapted to be connected in series with one of said lines and adapted to be connected in multiple with either of the other two lines, and electromagnetic mechanism adapted to automatically connect said selective apparatus in series with the broken line, substantially as described.

22. In combination, a central station, three lines leading therefrom to a series of substations, one of said lines being normally broken at each substation, electromagnetic selective apparatus at each of said substations adapted to be connected in series with one of said lines and adapted to be connected in multiple with either of the other two lines, and electromagnetic mechanism controlled from the central station adapted to automatically connect said selective apparatus in series with the broken line, substantially as described.

23. In combination, a central station, three lines leading therefrom to a series of substations, one of said lines being normally broken at each substation, electromagnetic selective apparatus at each of said substations adapted to be connected in series with one of said lines and adapted to be connected in multiple with either of the other two lines, and electromagnetic mechanism at each of said substations controlled from the central station adapted to automatically connect said selective apparatus in series with the broken line, and to automatically disconnect the multiple connections of said apparatus with one of the other two lines, substantially as described.

24. In combination, a central station, three lines leading therefrom to a series of substations, one of said lines being normally broken at each substation, electromagnetic selective apparatus at each of said substations adapted to be connected in series with one of said lines and adapted to be connected in multiple with either of the other two lines, and neutral electromagnetic mechanism adapted to automatically connect said selective apparatus in series with the broken line, substantially as described.

25. In combination, a central station, three lines leading therefrom to a series of substations, one of said lines being normally broken at each substation, electromagnetic selective apparatus at each of said substations adapted to be connected in series with one of said lines and adapted to be connected in multiple with either of the other two lines, and neutral electromagnetic mechanism adapted to automatically connect said selective apparatus in series with the broken line and to automatically disconnect the multiple connections of said selective apparatus with one of the other two lines, substantially as described.

26. In combination, a central station, three lines leading therefrom to a series of substations, one of said lines being normally broken at each substation, electromagnetic selective apparatus at each of said substations adapted to be connected in series with each one of said lines and adapted to be connected in multiple with either of the other two lines, and neutral electromagnetic mechanism controlled from the central station adapted to automatically connect said selective apparatus in series with the broken line, substantially as described.

27. In combination, a central station, three lines leading therefrom to a series of substations, one of said lines being normally broken at each substation, electromagnetic selective apparatus at each of said substations adapted to be connected in series with one of said lines and adapted to be connected in multiple with either of the other two lines, and neutral electromagnetic mechanism controlled from the central station adapted to automatically connect said selective apparatus in series with the broken line and to automatically disconnect the multiple connections of said selective apparatus with one of the other two lines, substantially as described.

28. In a selective party-line telephone system, the combination with a series of substations, electromagnetic selective apparatus at each of said substations, a connecting-line normally broken at each of said substations, a second line normally connected to the selective apparatus at each of said substations, a third line adapted to be connected in circuit with the selective apparatus at each of said substations, and neutral electromagnetic mechanism adapted to automatically connect said selective apparatus in series with the broken line, means adapted to automatically build up and restore said broken line and to break the normal connection with said second line and to connect said selective apparatus in circuit with said third line, the selective apparatus at any one substation being identical with that at all other substations, substantially as described.

29. In a selective party-line telephone system, the combination with a series of substations, of electromagnetic selective apparatus at each of said substations, a connecting-line normally broken at each of said substations, a second line normally connected to the selective apparatus at each of the substations, a third line adapted to be connected in circuit with the selective apparatus at each of the said substations, and electromagnetic means controlled from the central station adapted to automatically build up and restore said broken line and to break the normal connection with the said second line, and to connect said selective apparatus in circuit with said third line, the selective apparatus at any one substation being identical with that at all other substations, substantially as described.

30. In a selective party-line telephone system, the combination with a series of substations, of electromagnetic selective apparatus at each of said substations, a connecting-line normally broken at said substations, a second line normally connected with the selective apparatus at each of said substations, a third line adapted to be connected in circuit with the selective apparatus at each of said substations, and electromagnetic means adapted to automatically build up

and restore said broken line and to break the normal connection with said second line and to connect said selective apparatus in circuit with said third line, the selective apparatus at any one substation being identical with that at all other substations, substantially as described.

31. In a selective party-line telephone system, the combination with a series of substations, of suitable selective apparatus at each of said substations, a line connecting said substations normally broken at each of said substations, telephone instruments at each of said substations normally disconnected from said line, and means for connecting said telephone instruments in circuit with said broken line, substantially as described.

32. In a selective party-line telephone system, the combination with a series of substations, of suitable selective apparatus at each of said substations, a line adapted to connect said substations normally broken at each substation, a second line normally connected to the selective apparatus at each of said substations, telephone instruments at each of said substations normally disconnected from said lines, and means for connecting said telephone instruments in circuit with said broken line, substantially as described.

33. In a selective party-line telephone system, the combination with a series of substations, of suitable selective apparatus at each of said substations, a line adapted to connect said substations but normally broken at each of said substations, a second line normally connected with the selective apparatus at each of said substations, a third line adapted to be connected in multiple with the selective apparatus at each of said substations, telephone instruments at said substations normally disconnected from said broken line, and means adapted to connect said telephone instruments in circuit with said broken line, substantially as described.

34. The combination with a central station, of a line running from said central station broken at a series of substations, neutral electromagnetic mechanism adapted to build up a non-inductive electrical path through said broken line, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, and electromagnetic mechanism adapted to connect said signaling apparatus in circuit with two of said lines, substantially as described.

35. The combination with a central station, of a line running from said central station broken at a series of substations, neutral electromagnetic mechanism controlled from the central station adapted to build up a non-inductive electrical path through said broken line to any desired substation, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, and electromagnetic mechanism controlled from the central station adapted to connect said signaling apparatus in circuit with two of said lines, substantially as described.

36. The combination with a central station, of a line running from said central station broken at a series of substations, neutral electromagnetic mechanism controlled from the central station adapted to build up a non-inductive electrical path through said broken line to any desired substation, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, and electromagnetic mechanism controlled from said central station adapted to connect said signaling apparatus in circuit with two of said lines, substantially as described.

37. The combination with a central station, of a line running from said central station broken at a series of substations, electromagnetic mechanism controlled from the central station adapted to build up a non-inductive electrical path through said broken line to any desired substation, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, and electromagnetic mechanism controlled from said central station adapted to connect one of said lines with the signaling apparatus at any one of said substations, substantially as described.

38. The combination with a central station, of a line running from said central station broken at a series of substations, neutral electromagnetic mechanism controlled from the central station adapted to build up a non-inductive circuit through said broken line to any desired substation, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, and electromagnetic mechanism controlled from said central station adapted to connect said signaling apparatus in circuit with two of said lines, substantially as described.

39. The combination with a central station, of a line running from said central station broken at a series of substations, neutral electromagnetic mechanism controlled from the central station adapted to build up a non-inductive circuit through said broken line to any desired substation, other electromagnetic mechanism controlled from said central station adapted to break said electric circuit at said substations, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, and electromagnetic mechanism controlled from said central station adapted to connect said signaling apparatus in circuit with two of said lines, substantially as described.

40. The combination with a central station, of a line running from said central station broken at a series of substations, electromagnetic mechanism controlled from the central station adapted to build up a non-inductive circuit through said broken line to any desired substation, other electromagnetic mechanism controlled from said central station adapted to break said electric circuit at said substations, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, and electromagnetic mechanism controlled from said central station adapted to connect said signaling apparatus in circuit with two of said lines, substantially as described.

41. The combination with a central station, of a line running from said central station broken at a series of substations, electromagnetic mechanism controlled from the central station adapted to build up a non-inductive circuit through said broken line to any desired substation, other electromagnetic mechanism controlled from said central station adapted to break said electric circuit at said substations, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, electromagnetic mechanism at each of said substations controlled from said central station adapted to connect said signaling apparatus in circuit with two of said lines, substantially as described.

42. The combination with a central station, of a line running from the said central station broken at a series of substations, automatic mechanism adapted to build up said broken line, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, and mechanism adapted to connect said signaling apparatus in a non-inductive circuit with two of said lines, substantially as described.

43. The combination with a central station of a line running from said central station broken at a series of substations, electromagnetic mechanism adapted to build up a non-inductive electrical path through said broken line, return-circuits from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, and electromagnetic mechanism adapted to connect said signaling apparatus in a non-inductive circuit with two of said lines, substantially as described.

44. The combination with a central station, of a line running from said central station broken at a series of substations, electromagnetic mechanism controlled from the central station adapted to build up a non-inductive electrical path through said broken line to any desired substation, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, and electromagnetic mechanism controlled from said central station adapted to connect said signaling apparatus in a non-inductive circuit with two of said lines, substantially as described.

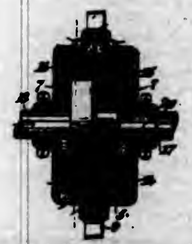
45. The combination with a central station, of a line running from said central station broken at a series of substations, electromagnetic mechanism controlled from the central station adapted to build up a non-inductive electrical path through said broken line to any desired substation, other electromagnetic mechanism controlled from said central station adapted to break said electric circuit at said substations, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, and electromagnetic mechanism controlled from said central station adapted to connect one of said lines with the signaling apparatus at any one of said substations, substantially as described.

46. The combination with a central station, of a line running from said central station broken at a series of substations, electromagnetic mechanism controlled from the central station adapted to build up a non-inductive electrical path through said broken line to any desired substation, other electromagnetic mechanism controlled from said central station adapted to break said electric circuit at said substations, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, and electromagnetic mechanism controlled from said central station adapted to connect said signaling apparatus in a non-inductive circuit with two of said lines, substantially as described.

810,386. **STRETCHER.** THOMAS J. BOWMAN, New Vienna, Ohio. Filed Dec. 17, 1903. Serial No. 185,333.

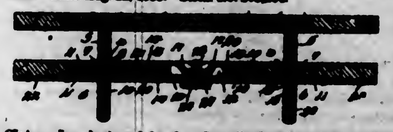
Claim.—In a stretcher, an expansible action comprising a coil-spring, handle having slotted ends in the ends of the spring and provided with longitudinal openings intersected by transverse openings, a non-expansible element extended longitudinally through the spring and having its terminals seated in the longitudinal openings of the shanks, and pins entered through the transverse openings in said shanks and terminals of the elements for connecting the latter with the heads.

810,387. **WHEEL.** GUSTAVE L. HEISER, Waverly, Iowa, assignor of one-fourth to Christian A. Peterman, and one-fourth to Glenn C. Hohenboken, both of Waverly, Iowa. Filed Mar. 3, 1905. Serial No. 248,272.



Claim.—In a wheel, a hollow hub, consisting of two sections bolted together and having peripheral socket members for spokes, an axle extended through the hub and having a longitudinal channel opening outward at the end, oppositely-wound springs in the hub having their outer ends secured to the hub and their inner ends secured in said channel, and keys in the channel to prevent lateral movement of the springs.

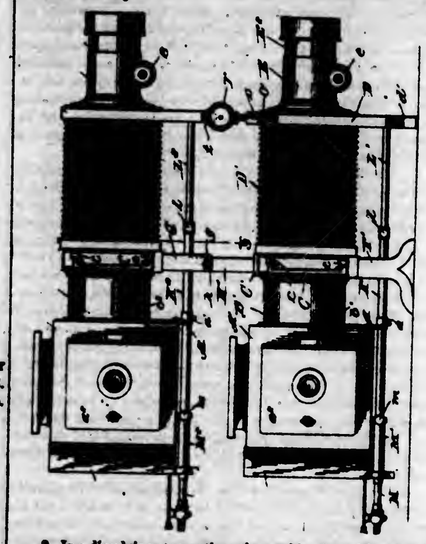
810,388. **TEMPORARY BINDER.** FRED S. JORDAN, Westminster, Mass. Filed Aug. 22, 1904. Serial No. 221,504.



Claim.—In a device of the class described, a clamping member, a pair of binder-posts carried thereby, a second clamping member having openings to receive said posts and provided with opposite longitudinal recesses communicating with an intermediate opening, a pair of locking members having opened arms disposed respectively in said recesses and adapted for locking engagement with the posts, an actuating member disposed in the intermediate opening and having a head movable between the adjacent ends of the locking members for moving the latter to locking position, and springs arranged to act on the locking members for automatically moving them to releasing position.

810,389. **STEREOPTICON.** GEORGE KLEMM, Chicago, Ill. Filed Sept. 12, 1904. Serial No. 224,069.

Claim.—1. In a dissolving-stereopticon the combination with a plurality of lanterns, of means for pivotally supporting one lantern above another to permit vertical and lateral oscillation, a bracket projecting upwardly from the lower lantern, a cooperating bracket depending from the upper lantern into the horizontal plane of said upwardly-projecting bracket, means for adjusting said brackets laterally toward and away from each other, and means interposed between the lanterns for relatively vertically oscillating the same.



2. In a dissolving-stereopticon the combination with a plurality of lanterns, of means for supporting one lantern above another to permit vertical and lateral oscillation, a bracket projecting upwardly from the lower lantern, a cooperating bracket depending from the upper lantern into the horizontal plane of said upwardly-projecting bracket, means for adjusting said brackets laterally toward and away from each other, and means interposed between the lanterns for relatively vertically oscillating the same.

3. In a dissolving-stereopticon the combination with a plurality of lanterns, of means for supporting one lantern above another to permit vertical and lateral oscillation, a pair of brackets projecting upwardly from the lower lantern a cooperating pair of brackets depending from the upper lantern, and a horizontal screw-threaded rod journaled in the upwardly-projecting brackets and extending through screw-threaded holes in the depending brackets.

4. In a dissolving-stereopticon the combination with a plurality of lanterns, of means for supporting one lantern above another to permit vertical and lateral oscillation, a pair of brackets projecting upwardly above the supporting-frame of the objective lens of the lower lantern, a cooperating pair of brackets depending from the supporting-frame of the objective lens of the upper lantern, and a screw-threaded rod journaled in the upwardly-projecting brackets and extending through screw-threaded holes in the depending brackets.

5. In a dissolving-stereopticon the combination with a plurality of lanterns, of brackets depending from the slide-holder of the upper lantern having horizontal slots in their lower ends, cooperating brackets projecting upwardly from the slide-holder of the lower lantern, screws extending through said slots and engaging the upper ends of the lower brackets, and means for oscillating the upper lantern relatively to the lower lantern vertically and laterally upon said screws as fulcrums.

6. In a dissolving-stereopticon the combination with a plurality of lanterns, of brackets depending from the slide-holder of the upper lantern having horizontal slots in their lower ends, cooperating brackets projecting upwardly from the slide-holder of the lower lantern, screws extending through said slots into engagement with the upper ends of the lower brackets, a pair of brackets projecting upwardly from the supporting-frame for the objective lenses of the lower lantern, a cooperating pair of brackets depending from the supporting-frame of the objective lens of the upper lantern, a screw-threaded rod

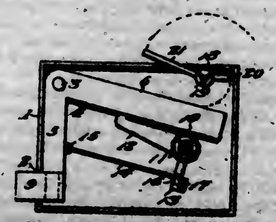
journaled in the pair of upwardly-projecting brackets and extending through screw-threaded holes in the pair of depending brackets, and means interposed between the lanterns for relatively vertically oscillating the same.

7. In a dissolving-stereopticon the combination with a plurality of lanterns, of brackets depending from the slide-holder of the upper lantern having horizontal slots in their lower ends, coöperating brackets projecting upwardly from the slide-holder of the lower lantern, screws extending through said slots into engagement with the upper ends of the lower brackets, a pair of brackets projecting upwardly from the supporting-frame for the objective lenses of the lower lantern, a coöperating pair of brackets depending from the supporting-frame of the objective lens of the upper lantern, a screw-threaded rod journaled in the pair of upwardly-projecting brackets and extending through screw-threaded holes in the pair of depending brackets, and means interposed between the lower lantern and the brackets projecting upwardly above the objective-lens-supporting frame thereon for raising and lowering said brackets.

8. In a dissolving-stereopticon the combination with a plurality of lanterns, of brackets depending from the slide-holder of the upper lantern having horizontal slots in the lower ends, coöperating brackets projecting upwardly from the slide-holder of the lower lantern, screws extending through said slots into engagement with the upper ends of the lower brackets, a pair of brackets projecting upwardly from the supporting-frame for the objective lenses of the lower lantern, a coöperating pair of brackets depending from the supporting-frame of the objective lens of the upper lantern, a screw-threaded rod journaled in the pair of upwardly-projecting brackets and extending through screw-threaded holes in the pair of depending brackets, ears having vertical screw-threaded holes projecting laterally from each side of the objective-lens-supporting frames of the lower lantern, right and left screw-threaded rods engaging the holes through said ears, lateral ears carried by the brackets projecting upwardly above the objective-lens-supporting frame through which said rods rotatably extend, and means for rotating said rods in opposite directions.

9. In a dissolving-stereopticon, the combination with a plurality of lanterns, of brackets depending from the slide-holder of the upper lantern having horizontal slots in their lower ends, coöperating brackets projecting upwardly from the slide-holder of the lower lantern, screws extending through the said slots into engagement with the upper ends of the lower brackets, means for oscillating the upper lantern laterally with respect to the lower lantern, and means interposed between the objective-lens-supporting frames of the lanterns for adjusting the same at each point toward and away from each other.

810,840. SPRINGLESS LOCK. HENRY K. HESS, Lawton, Okla. Filed July 6, 1904. Serial No. 215,969.



Claim.—1. In a device of the class described, a casing, a latch-bolt pivoted therein and comprising a pair of arms, one of said arms being substantially horizontal and acting by gravity to maintain the bolt normally in latching position, a knob-spindle rotatively disposed in the casing at a point beneath and adjacent to the free end of the horizontal arm, and a pair of projections carried by the spindle, one of said projections being adapted to operate upon the horizontal arm of the bolt for moving the latter to non-latching position, and the other projection being operatively connected with the other arm of the bolt for acting upon the latter when the spindle is reversely rotated.

2. In a device of the class described, a casing, a latch-bolt, pivotally mounted therein and comprising a vertical and a substantially horizontal arm, said horizontal arm acting by gravity to maintain the bolt normally in latching position, a knob-spindle rotatively disposed in the casing beneath and adjacent to the free end of the horizontal arm, a pair of projections carried by the spindle, one of said projections being adapted to act upon the horizontal arm of the bolt for moving the latter to non-latching position, and a rigid element connecting the other of said projections with the vertical arm of the bolt for moving the latter to unlatched position when the spindle is rotated reversely.

810,841. BOX. RICHMOND S. A. MOORE, Ridgedale, Tenn. Filed Sept. 2, 1905. Serial No. 276,886.

Claim.—1. A box formed with circumferentially-arranged ribs, and a cover therefor having means to engage one of said ribs to lock the cover against movement in either direction.

2. A box formed with diametrically opposite ribs, an abutment projecting from one of said ribs, a cover to coöperate with said box, said cover being provided with lugs to engage beneath the ribs and with means to engage said abutment.

3. A box comprising a body having a vertically-arranged neck, diametrically-arranged ribs formed on said neck, an abutment depending from one of said ribs, a cover arranged to inclose said neck, lugs projecting inwardly from the cover and adapted to ride beneath the ribs, and a spring carried by the cover to engage said abutment.

4. A box comprising a body, a neck of less diameter than said body and projecting therefrom, diametrically-opposed ribs arranged circumferentially on said neck, a cover equal in diameter to the diameter of the body, lugs projecting inwardly from said cover, and adapted to ride beneath the ribs on the neck, and a spring carried by the cover and arranged to engage one of said ribs.

5. A box comprising a body, a neck of less diameter than said body and projecting therefrom, diametrically-opposed ribs arranged circumferentially on said neck, an abutment depending from one of said ribs, a cover equal in diameter to the diameter of the body, lugs projecting inwardly from said cover and adapted to ride beneath the ribs on the neck, and a spring carried by the cover and arranged to engage said abutment.

6. A box formed with a rib, a cover for the box, and means carried by the cover to engage said rib to lock the cover against movement in either direction.

810,842. HEAT-NON-CONDUCTING MATERIAL. GUSTAV H. HELLER, Kiel, and EDUARD JANSE, Hamburg, Germany. Filed Aug. 29, 1904. Serial No. 222,222.

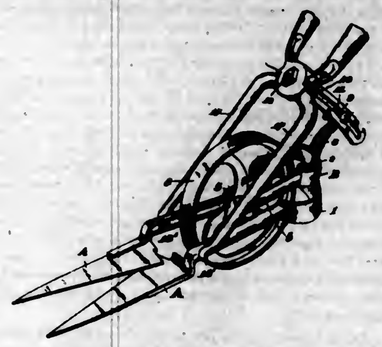
Claim.—A heat-non-conducting material consisting of refractory clay, fibers of amianthus, infusory earth, ground cork, vegetable fibers, yeast and nitrate of alumina, these substances being mixed so as to form a pasty mass, or pressed into shells, plates or blocks suitable to be used for covering steam-boilers, pipes, tanks or the like, for the purpose and substantially as set forth.

810,843. CONCRETE-BLOCK MOLD. JOHN M. PETTIJOHN, Terre Haute, Ind. Filed May 22, 1905. Serial No. 261,255.

Claim.—1. The combination in a mold, of a hopper, a mold-box formed by separable sides and ends, hinged at their upper edge to the hopper, means whereby the mold may be lifted from the molded block, and means connecting the lifting means with the hinged sides and ends of the mold-box, whereby said mold-box sides and ends are imparted swinging action, substantially as described.

2. The combination in a mold, of a hopper, a mold-box having separable sides and ends hinged at their upper edge to the hopper, a rigid frame surrounding the mold-box, and arms hingedly connecting the mold-box, sides and ends, with the surrounding frame, substantially as described.

810,844. LAWN-TRIMMER. EDWARD PIERCE and EDWARD LANE, Burlington, Iowa. Filed Mar. 30, 1905. Serial No. 252,255.



Claim.—1. A lawn-trimmer comprising a frame, means for supporting the latter as it is pushed along the ground, shears carried by the frame, handles connected with the shears, a shank on the frame, and means extending from the handles to the shank for varying the angle or inclination of the handles with respect to the shears and maintaining such angle or inclination.

2. A lawn-trimmer comprising a support, a frame, shears carried by the frame and sustained by the support and handles connected with the rear end of the frame in rear of the support and with the shears forward of the support whereby a predetermined relation between shears and handles is maintained and the position of the shears is within the control of the operator at all times.

3. A lawn-trimmer comprising shears, a frame to which they are secured, cross-levers connected with the shears and a segment adjustably connected with the frame, upon which segment the levers are fulcrumed.

4. In lawn-trimmers, the combination with spring-shears, a frame rigidly secured to said shears, and a wheel upon which the frame is supported, of a segment adjustably connected with the frame, cross-levers fulcrumed on the segment and connected with the blades of the shears.

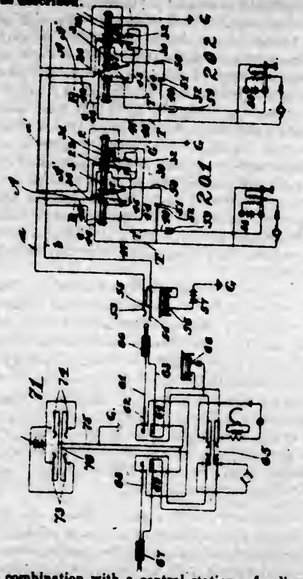
5. In lawn-trimmers, the combination with spring-shears, a frame rigidly secured to said shears, and a wheel upon which the frame is supported, of a segment adjustably connected with the frame, cross-levers fulcrumed on the segment and connected with the blades of the shears, and shoulders or stops formed on the levers for limiting the spread of the shears.

6. In a lawn-trimmer, the combination with spring-shears, a frame having a lug to which the shears are secured, the frame provided with a pair of forwardly-projecting jaws, a wheel journaled between the jaws and a rearwardly-projecting shank, of a segment connected with the shank, cross-levers fulcrumed on said segment and connected with the blades of the shears.

7. In a lawn-trimmer, the combination with spring-shears, a frame having a lug to which the shears are secured, the frame provided with a pair of projecting jaws, a wheel journaled between the jaws, and a rearwardly-projecting shank, of a segment adjustably connected with the shank, cross-levers fulcrumed on said segment, and connected with the blades of the shears.

810,845. TELEPHONE PARTY-LINE SYSTEM. ARTHUR F. POOLE and FRANK B. MAIS, Wheeling, W. Va. Filed Oct. 17, 1902. Serial No. 127,113.

Claim.—1. The combination with a central station, of a line running from said central station broken at a series of substations, electromagnetic mechanism controlled from the central station adapted to build up a non-inductive electrical path through said broken line to any desired substation, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, electromagnetic mechanism at each of said substations controlled from said central station adapted to connect said signaling apparatus in circuit with said lines, and means at each of said substations affording a secondary control over the electromagnetic connecting apparatus at the corresponding substation, substantially as described.



2. The combination with a central station, of a line running from said central station broken at a series of substations, electromagnetic mechanism controlled from the central station adapted to build up a non-inductive circuit through said broken line to any desired substation, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, electromagnetic mechanism at each of said substations controlled from said central station adapted to connect the said second line with the signaling apparatus at any of said substations, and means at each of said substations affording a secondary control over the electromagnetic connecting apparatus at the corresponding station, substantially as described.

3. The combination with a central station, of a line running from said central station broken at a series of substations, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, electromagnetic mechanism at each of said substations controlled from said central station adapted to connect the said second line with the signaling apparatus at any of said substations, and means at each of said substations affording a secondary control over the electromagnetic connecting apparatus at the corresponding station, substantially as described.

4. The combination with a central station, of a line running from said central station broken at a series of substations, electromagnetic mechanism controlled from the central station adapted to build up a non-inductive circuit through said broken line to any desired substation, other electromagnetic mechanism controlled from said central station adapted to break said electric circuit at said substations, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, electromagnetic mechanism at each of said substations controlled from said central station adapted to connect the said second line with the signaling apparatus at any of said substations, and means at each of said substations affording a secondary control over the electromagnetic connecting apparatus at the corresponding station, substantially as described.

5. In a selective party-line system, the combination with switching mechanism comprising a means of recovery for making or breaking electric circuits, of electromagnetic means for actuating said mechanism, and means for causing current to flow through said electromagnetic means, the operation of said switching mechanism being accomplished wholly upon the cessation of said current-flow, substantially as described.

6. The combination with a central station, of a line running from the said central station broken at a series of substations, electromagnetic mechanism adapted to be actuated by suitable electrical impulses to build up a non-inductive circuit through said broken line to any desired station, other electromagnetic mechanism adapted to be actuated by a suitable electric impulse to break said electric circuit at said substations, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, electromagnetic mechanism at each of said substations adapted to be actuated by an electric impulse of suitable polarity to connect the said second line with the signaling apparatus at any of the substations, means at each of the substations affording a secondary control of the electromagnetic connecting apparatus at the corresponding station, and means provided at the central station whereby the operator may control said electromagnetic mechanism by causing suitable electric impulses to flow therethrough, substantially as described.

7. The combination with a central station, of a line running from said central station broken at a series of substations, neutral electromagnetic mechanism controlled from the central station adapted to build up a non-inductive electrical path through said broken line to any desired substation, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, electromagnetic mechanism at each of said substations controlled from said central station adapted to connect said signaling apparatus in circuit with two of said lines, and means at each of said substations affording a secondary control over the electromagnetic connecting apparatus at the corresponding substation, substantially as described.

8. The combination with a central station, of a line running from said central station broken at a series of substations, electromagnetic mechanism controlled from the central station adapted to build up a non-inductive electrical path through said broken line to any desired substation, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, electromagnetic mechanism at each of said substations controlled from said central station adapted to connect one of said lines with the signaling apparatus at any of said substations, and means at each of said substations affording a secondary control over the electromagnetic connecting apparatus at the corresponding station, substantially as described.

9. The combination with a central station, of a line running from said central station broken at a series of substations, electromagnetic mechanism controlled from the central station adapted to build up a non-inductive electrical path through said broken line to any desired substation, other electromagnetic mechanism controlled from said central station adapted to break said electrical path at said substations, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, electromagnetic mechanism at each of said substations controlled from said central station adapted to connect one of said lines with the signaling apparatus at any of said substations, and means at each of said substations affording a secondary control over the electromagnetic connecting apparatus at the corresponding station, substantially as described.

10. The combination with a central station, of a line running from said central station broken at a series of substations, electromagnetic mechanism controlled from the central station adapted to build up a non-inductive circuit through said broken line to any desired substation, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, electromagnetic mechanism at each of said substations controlled from said central station adapted to connect said signaling apparatus in circuit with two of said lines, and means at each of said substations affording a secondary control over the electromagnetic connecting apparatus at the corresponding station, substantially as described.

11. The combination with a central station, of a line running from the central station broken at a series of substations, a return-circuit from said substations to said central station, electric signaling apparatus at each of said substations, a second line connecting all of said substations with the central station, electromagnetic mechanism at each of said substations controlled from said central station adapted to connect said signaling apparatus in circuit with two of said lines, and means at each of said substations affording a secondary control over the electromagnetic connecting apparatus at the corresponding station, substantially as described.

12. In a selective party-line telephone system, the combination with a central station, of a line running therefrom to a series of substations normally broken at each of said substations, signaling apparatus at each of said substations normally disconnected from said broken line, and means whereby the control operator may connect the signaling apparatus at two of said substations in circuit simultaneously with said broken line, substantially as described.

13. In a selective party-line telephone system, the combination with a central station, of a line running therefrom to a series of substations normally broken at each of said substations, signaling apparatus at each of said substations normally disconnected from said broken line, and means whereby the central operator may connect the signaling apparatus at a plurality of said substations in circuit simultaneously with said broken line, substantially as described.

14. In a selective party-line telephone system, the combination with a central station, of lines running from the central station to a series of substations, one of said lines being normally broken at each substation, signaling apparatus at each substation normally disconnected from said broken line, and means controlled from each substation and from the central station, whereby the corresponding signaling apparatus may be connected with the broken line, substantially as described.

15. In a selective party-line system, the combination with a central station, of lines running from the central station to a series of substations, one of said lines being normally broken at each substation, signaling apparatus at each substation normally disconnected from said broken line, and means primarily controlled from the central station whereby any substation signaling apparatus may be connected with the broken line and secondarily controlled from each substation, whereby the corresponding signaling apparatus may be connected with the broken line, substantially as described.

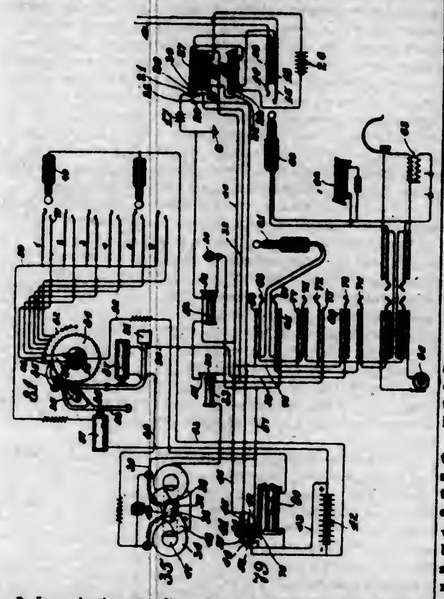
16. In a selective party-line system, the combination with a central station, of lines running from the central station to a series of substations, one of said lines being normally broken at each substation, signaling apparatus at each substation normally disconnected from said broken line, and means controlled from each substation, and from the central station, whereby the corresponding signaling apparatus may be connected with the broken line, substantially as described.

17. In a selective party-line system, the combination with a central station, of lines running from the central station to a series of substations, one of said lines being normally broken at each substation, means for building up said broken line through any number of said substations, signaling apparatus at each substation normally disconnected from said broken line, and means controlled from each substation, and from the central station, whereby the corresponding signaling apparatus may be connected with said broken line, substantially as described.

810,846. PARTY-LINE SIGNALING SYSTEM. ARTHUR F. POOLE and FRANK B. HALL, Wheeling, W. Va. Filed Oct. 13, 1902. Serial No. 127,114.

Claim.—1. In a selective party-line system, the combination with the central station, of lines running therefrom to a series of substations, signaling apparatus at each of said substations normally disconnected from said lines, means at each substation absolutely controlled from the central station, and from the said substation, whereby the corresponding signaling apparatus may be connected with said lines, said means whereby an actuation of said first means controlled from the corresponding substation, establishes a condition such that the substation control at the other substations of the said first means is rendered ineffective, substantially as described.

2. In a selective party-line system, the combination with the central station of lines running therefrom to a series of substations, signaling apparatus at each of said substations, normally disconnected from said party-lines, means primarily controlled from the central station, and secondarily controlled from each substation, whereby the corresponding signaling apparatus may be connected with said lines and means whereby an actuation of said first means controlled from any one substation, establishes a condition such that the substation control at the other substations of said first means is rendered ineffective, substantially as described.



3. In a selective party-line system, the combination with a central station, of lines running therefrom to a series of substations, signaling apparatus at each of said substations normally operatively disconnected from said lines, means controlled from the central station whereby any of the signaling apparatus may be operatively connected with the said lines, said means being subject to a secondary control from each substation, the control exercised from any one substation serving secondarily to govern the operative connection of the signaling apparatus at the same substation with said lines, and means whereby an actuation of said first means due to the control exercised from any one substation establishes a condition such that the substation control at the other substations of the said first means is rendered ineffective, substantially as described.

4. In a selective party-line system, the combination with a central station, of lines running therefrom to a series of substations, signaling apparatus at each of said substations normally operatively disconnected from the said lines, means primarily controlled from the central station whereby the signaling apparatus at any substation may be operatively connected with the lines and secondarily controlled from each substation, the control exercised from any one substation serving secondarily to govern the operative connection of the signaling apparatus at the same substation with said lines, and means whereby an actuation of said first means due to the control exercised from the central station establishes a condition such that the substation control at the other substations of said first means is rendered ineffective, substantially as described.

5. In a selective party-line system, the combination with a central station, of lines running therefrom to a series of substations, signaling apparatus at each of said substations normally operatively disconnected from said lines, means primarily controlled from the central station whereby the signaling apparatus at any substation may be operatively connected with said lines and secondarily controlled from each substation, the control exercised from any one substation serving secondarily to govern the operative connection of the signaling apparatus at the same substation with said lines, and means whereby an actuation of said first means due to a control exercised either from the central station or any one substation establishes a condition such that the substation control at the other substations of the said first means is rendered ineffective, substantially as described.

6. In a selective party-line system, the combination with a central station, of lines running from the central station to a series of substations, one of said lines being normally broken at each substation, signaling apparatus at each of said substations normally disconnected from said broken line, means controlled from the central station whereby any of the signaling apparatus may be connected with the broken line, and means controlled from each substation whereby the corresponding signaling apparatus may be connected with the broken line, substantially as described.

7. In a selective party-line system, the combination with a central station, of lines running from the central station to a series of substations, one of said lines being normally broken at each substation, signaling apparatus at each substation normally disconnected from said broken line, means primarily controlled from the central station whereby any substation signaling apparatus may be connected with the broken line and secondarily controlled from each substation whereby the corresponding signaling apparatus may be connected with the broken line, and means intermediately set in operation by an actuation of said first means whereby the said broken line is built up, substantially as described.

8. In a selective party-line system, the combination with the central station, of lines running from the central station to a series of substations, one of said lines being normally broken at each substation, signaling apparatus at each substation normally disconnected from said broken line, means controlled from each substation whereby the corresponding signaling apparatus may be connected with said broken line, and means whereby an actuation of said first means controlled from any one substation establishes a condition such that the substation control at the other substations of the said first means is rendered ineffective, substantially as described.

9. In a selective party-line system, the combination with a central station, of lines running from the central station to a series of substations, one of said lines being normally broken at each substation, signaling apparatus at each substation normally disconnected from said broken line, means controlled from the central station whereby any of the signaling apparatus may be connected with said broken line, said means being secondarily controlled from each substation, whereby the corresponding signaling apparatus may be connected with said lines, and means whereby an actuation of said first means due to the control exercised from any one substation establishes a condition such that the substation control at the other substations of the said first means is rendered ineffective, substantially as described.

10. In a selective party-line system, the combination with a central station, of lines running from the central station to a series of substations, one of said lines being normally broken at each substation, signaling apparatus at each substation normally disconnected from said broken line, means primarily controlled from the central station whereby the signaling apparatus at any substation may be connected with the broken line, and secondarily controlled from each substation, whereby the corresponding signaling apparatus may be connected with said broken line, and means whereby an actuation of said first means due to a control exercised from the central station establishes a condition such that the substation control at the other substations of said first means is rendered ineffective, substantially as described.

11. In a selective party-line system, the combination with a central station, of lines running from the central station to a series of substations, one of said lines being normally broken at each substation, signaling apparatus at each substation normally disconnected from said broken line, means primarily controlled from the central station whereby the signaling apparatus at any substation may be connected with the broken line, and secondarily controlled from each substation, whereby the corresponding signaling apparatus may be connected with said broken line, and means whereby an actuation of said first means due to a control exercised either from central or from any one substation establishes a condition such that the substation control at the other substations of the said first means is rendered ineffective, substantially as described.

12. In a selective party-line system, the combination with a central station, of lines running from the central station to a series of substations, one of said lines being normally broken at each substation; and means secondarily controlled from any one substation and primarily set in operation at the central station, adapted to build up said broken line automatically, substantially as described.

13. In a selective party-line system, the combination with a central station, of lines running from the central station to a series of substations, one of said lines being normally broken at each substation, and means primarily controlled from the central station and secondarily controlled from any substation, adapted to build up said broken line automatically, substantially as described.

14. In a selective party-line system, the combination with a central station, of lines running from the central station to a series of sub-

stations, one of the lines being normally broken at each substation, means controlled and set in operation at the central station adapted to build up said broken line automatically, and means for secondarily controlling said first means from each of said substations, substantially as described.

15. In a selective party-line system, the combination with a central station, of lines running therefrom to a series of substations, one of said lines being normally broken at each of said substations, a line-signal associated with the said lines at the central station, means located at each substation adapted to cause the actuation of said line-signal, means set in operation by the actuation of said line-signal adapted to build up said broken line, substantially as described.

16. In a selective party-line system, the combination with a central station, of lines running therefrom to a series of substations, one of said lines being normally broken at each of said substations, a cord-circuit at the central station adapted for connection with said lines, a line-signal associated with the said lines at the central station, means located at each substation adapted to cause the actuation of said line-signal, means set in operation by the actuation of said line-signal adapted to build up said broken line, and means whereby the substation control of the line-signal is rendered ineffective upon connection of said cord-circuit with said lines, substantially as described.

17. In a selective party-line system, the combination with the central station, of lines running therefrom to a series of substations, one of said lines being normally broken at each of said substations, a line-signal associated with the said lines at the central station, means located at each substation adapted to cause the actuation of said line-signal, and means set in operation by the actuation of said line-signal but primarily controlled from the said central station, whereby the broken line is automatically built up, substantially as described.

18. In a selective party-line system, the combination with a central station, of lines running therefrom to a series of substations, one of said lines being normally broken at each of said substations, a cord-circuit at the central station adapted for connection with said lines, a line-signal associated with the lines at the central station, means located at each substation adapted to cause the actuation of said line-signal, means set in operation by the actuation of said line-signal but primarily controlled from the said central station, whereby the broken line is automatically built up, and means whereby the substation control of the line-signal is rendered ineffective upon the connection of said cord-circuit with said lines, substantially as described.

19. In a selective party-line system, the combination with the central station of lines running therefrom to a series of substations, one of said lines being normally broken at each substation, a cord-circuit at the central station adapted for connection with said lines, a line-signal associated with the lines at the central station, means located at each substation adapted to cause the actuation of said line-signal, means set in operation by the actuation of said line-signal but primarily controlled from said central station, whereby the broken line is automatically built up, and means whereby the substation control of said line-signal is rendered ineffective upon an actuation of the said line-signal caused from any one substation, substantially as described.

20. In combination, a source of electric current, a pole-changing switch associated therewith, an electromagnet adapted to actuate said pole-changing switch, switching means adapted to make connection with successive contacts, electromagnetic mechanism adapted to cause the step-by-step shifting of said switching means to successive contacts, and an electric circuit including the source of current, the switching means and the electromagnet adapted to actuate the pole-changing switch, said circuit being adapted to be completed through any predetermined contact, whereby the electromagnet will be energized to actuate the pole-changing switch upon a predetermined step of the switching means, substantially as described.

21. In combination, a source of electric current, a pole-changing switch associated therewith, an electromagnet adapted to actuate said pole-changing switch, switching means adapted to make connection with successive contacts, electromagnetic mechanism adapted to cause a one-step shifting of said switching means to a successive contact upon a cessation of current-flow therethrough, a periodically-interrupted electric current flowing through said electromagnetic mechanism, whereby a step-by-step shifting of said switching means is caused, and an electric circuit including the source of current, the switching means and the electromagnet adapted to actuate the pole-changing switch, said circuit being adapted to be completed through any predetermined contact, whereby the electromagnet will be energized to actuate the pole-changing switch upon a predetermined step of the switching means, substantially as described.

22. In combination, a source of electric current, a pole-changing switch associated therewith, an electromagnet adapted to actuate said pole-changing switch, switching means adapted to make connection with successive contacts, an electromagnet adapted to cause the one-step shifting of said switching means to a successive contact upon a cessation of current-flow therethrough, means adapted to cause a periodically-interrupted current to flow through said electromagnet, and an electric circuit including the source of current, the switching means and the electromagnet adapted to actuate the pole-changing switch, said circuit being adapted to be completed through any predetermined contact, whereby the electromagnet will be energized to actuate the pole-changing switch upon a predetermined step of the switching means, substantially as described.

23. In combination, a source of electric current, a pole-changing switch associated therewith, an electromagnet adapted to actuate said pole-changing switch, switching means adapted to make connection with successive contacts, an electromagnet adapted to cause the one-step shifting of said switching means upon a cessation of current-flow therethrough, means controlled from the central station adapted to cause a periodically-interrupted current to flow through said electromagnet, and an electric circuit including the source of current, the switching means and the electromagnet adapted to actuate the pole-changing switch, said circuit being adapted to be completed through any predetermined contact, whereby the electromagnet will be energized to actuate the pole-changing switch upon a predetermined step of the switching means, substantially as described.

24. In combination, a source of electric current, a pole-changing switch associated therewith, an electromagnet adapted to actuate said pole-changing switch, switching means adapted to make connection with successive contacts, electromagnetic mechanism adapted to cause the step-by-step shifting of said switching means to successive contacts, an electric circuit including the source of current, the switching means and the electromagnet adapted to actuate the pole-changing switch, a selector-jack connected with each of said contacts, and a selector-plug adapted for insertion within any of said jacks, thereby completing said electric circuit through any predetermined contact, whereby the electromagnet will be energized to actuate the pole-changing switch upon a predetermined step of the switching means, substantially as described.

25. In combination, a source of electric current, a pole-changing switch associated therewith, an electromagnet adapted to actuate said pole-changing switch, switching means adapted to make connection with successive contacts, electromagnetic mechanism adapted to cause the step-by-step shifting of said switching means to successive contacts, an electric circuit including the source of current, the switching means and the electromagnet adapted to actuate the pole-changing switch, a selector-jack connected with each of said contacts, a selector-plug adapted for insertion within any of said jacks, thereby completing said electric circuit through any predetermined contact whereby the electromagnet will be energized to actuate the pole-changing switch upon a predetermined step of the switching means, and means whereby the insertion of the selector-plug within any selector-jack will cause the restoration of the switching means to its normal condition, substantially as described.

26. In combination, a source of electric current, a pole-changing switch associated therewith, an electromagnet adapted to actuate said pole-changing switch, switching means adapted to make connection with successive contacts, electromagnetic mechanism adapted to cause the step-by-step shifting of said switching means to successive contacts, an electric circuit including the source of current, the switching means and the electromagnet adapted to actuate the pole-changing switch, a selector-jack connected with each of said contacts, a selector-plug adapted for insertion within any of said jacks, thereby completing said electric circuit through any predetermined contact, whereby the electromagnet will be energized to actuate the pole-changing switch upon a predetermined step of the switching means, and means whereby the removal of the selector-plug from any selector-jack will cause the restoration of the switching means to its normal condition, substantially as described.

27. In combination, a source of electric current, a pole-changing switch associated therewith, an electromagnet adapted to actuate said pole-changing switch, switching means adapted to make connection with successive contacts, electromagnetic mechanism adapted to cause the step-by-step shifting of said switching means to successive contacts, an electric circuit including the source of current, the switching means and the electromagnet adapted to actuate the pole-changing switch, means adapted to close or break said circuit through any predetermined contact, and means whereby the actuation of said means to close said circuit causes a restoration of said switching means to its normal condition, substantially as described.

28. In combination, a source of electric current, a pole-changing switch associated therewith, an electromagnet adapted to actuate said pole-changing switch, switching means adapted to make connection with successive contacts, electromagnetic mechanism adapted to cause the step-by-step shifting of said switching means to successive contacts, an electric circuit including the source of current, the switching means and the electromagnet adapted to actuate the pole-changing switch, means adapted to close or break said circuit through any predetermined contact, and means whereby the actuation of said means to break said circuit causes a restoration of said switching means to its normal condition, substantially as described.

29. In combination, a source of electric current, a pole-changing switch associated therewith, an electromagnet adapted to actuate said pole-changing switch, switching means adapted to make connection with successive contacts, electromagnetic mechanism adapted to cause the step-by-step shifting of said switching means to successive contacts, an electric circuit including the source of current, the switching means and the electromagnet adapted to actuate the pole-changing switch, a selector-jack connected with each of said contacts, a selector-plug adapted for insertion within any of said jacks, thereby completing said electric circuit through any predetermined contact, whereby the electromagnet will be energized to actuate the pole-changing switch upon a predetermined step of the switching means, and an auxiliary contact in each of said selector-jacks adapted to make momentary contact with said selector-plug upon insertion in or removal from said jack, said contact being adapted to close an electric circuit through electromagnetic mechanism adapted to cause the restoration of said switching means to its normal condition, substantially as described.

30. In combination, a source of electric currents, two circuits electrically connected therewith, means for causing the current-flow from said source to be intermittent, means for reversing the connection of the first of said circuits with said source of currents, and means adapted to disconnect the second circuit from said source during the reversal of the connection of said first circuit, substantially as described.

31. In combination, a source of electric currents, two circuits electrically connected therewith, means for causing the current-flow from said source to be intermittent, a pole-changing switch for reversing the connection of the first of said circuits with said source of currents, and means adapted to disconnect the second circuit from said source during reversal of the connection of said first circuit, substantially as described.

32. In a selective party-line system, the combination with a central station of three lines running therefrom to a series of substations, signaling apparatus at each of said substations normally operatively disconnected from said lines, means at each substation absolutely controlled from the central station and secondarily controlled from the said substation, whereby the corresponding signaling apparatus may be connected with two of said lines, and means whereby an actuation of said first means controlled from the corresponding substation, establishes a condition such that the substation control of the said first-mentioned means is rendered ineffective, substantially as described.

33. In a selective-party-line system, the combination with a central station of three lines running therefrom to a series of substations, signaling apparatus at each of said substations, normally operatively disconnected from said lines, means at each substation directly controlled from the said substation, whereby the corresponding signaling apparatus may be connected with two of said lines, and means whereby an actuation of said first means controlled from any substation, establishes a condition such that the substation control of the said first means is rendered ineffective, substantially as described.

34. In a selective party-line system, the combination with a central station of lines running from the central station to a series of substations, one of said lines being normally broken at each substation, signaling apparatus at each substation normally disconnected from said broken line, means controlled from each substation, whereby the corresponding signaling apparatus may be connected with the broken line, and means automatically set in operation by an actuation of said first means, whereby the said broken line is built up, substantially as described.

35. In a selective party-line system, the combination with a central station of lines running from the central station to a series of substations, one of said lines being normally broken at each substation, and means controlled from any one substation and set in operation at the central station, adapted automatically to build up a non-inductive circuit through said broken line, substantially as described.

36. In a selective party-line system, the combination with a central station of lines running from the central station to a series of substations, one of said lines being normally broken at each substation, and means primarily controlled from the central station, and secondarily controlled from any substation, adapted automatically to build up a non-inductive circuit through said broken line, substantially as described.

37. In a selective party-line system, the combination with a central station of lines running from the central station to a series of substations, one of said lines being normally broken at each substation, means controlled and set in operation at the central station, adapted automatically to build up a non-inductive circuit through said broken line and means for secondarily controlling said first means from each of said substations, substantially as described.

38. In a selective signaling party-line system, the combination with a central station of lines running therefrom to a series of substations, one of said lines being normally broken at each substation, a cord-circuit at the central station adapted for connection with said lines, a line-signal associated with said lines at the central station, means located at each substation, adapted to cause the actuation of said line-signal, and means whereby the substation control of the line-signal is rendered ineffective upon the connection of said cord-circuit with said lines, substantially as described.

39. In a selective party-line system, the combination with a central station, of lines running therefrom to a series of substations, one of said lines being normally broken at each substation, a cord-circuit at the central station adapted for connection with said lines, a line-signal associated with the lines at the central station, means located at each substation, adapted to cause the actuation of said line-signal, whereby the broken line is automatically built up, and whereby the substation control of said line-signal is rendered ineffective upon an actuation of the line-signal, caused by the control exercised from any one substation, substantially as described.

40. In combination a source of electric current, current-reversing means associated therewith, an electromagnet adapted to actuate said current-reversing means, switching means adapted to make connection with successive contacts, electromagnetic mechanism adapted to cause the step-by-step shifting of said switching means to successive contacts and an electric circuit including the source of current, the switching means and the electromagnet adapted to actuate the current-reversing means, said circuit being adapted to be completed through any predetermined contact whereby the electromagnet will be energized to actuate the current-reversing means upon a predetermined step of the switching means, substantially as described.

41. In combination, a source of electric current, current-reversing means associated therewith, an electromagnet adapted to actuate said current-reversing means, switching means adapted to make connection with successive contacts, electromagnetic mechanism adapted to cause a one-step shifting of said switching means to successive contacts upon a cessation of current-flow therethrough, a periodically-interrupted electric current flowing through said electromagnetic mechanism, whereby a step-by-step shifting of said switching means is caused, and an electric circuit including the source of current, the switching means and the electromagnet adapted to actuate the current-reversing means, said circuit being adapted to be completed through any predetermined contact whereby the electromagnet will be energized to actuate the current-reversing means upon a predetermined step of the switching means, substantially as described.

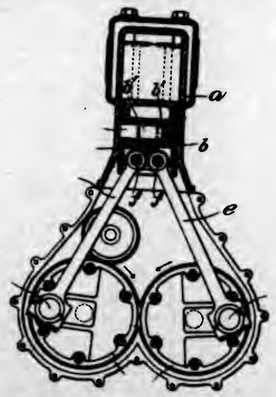
42. In combination, a source of electric current, current-reversing means associated therewith, an electromagnet adapted to actuate said current-reversing means, switching means adapted to make connection with successive contacts, electromagnetic mechanism adapted to cause the step-by-step shifting of said switching means to successive contacts, an electric circuit including the source of current, the switching means and the electromagnet adapted to actuate the current-reversing means, means adapted to close or break said circuit through any predetermined contact, and means whereby the actuation of said means to close said circuit, causes a restoration of said switching means to its normal condition, substantially as described.

43. In combination, a source of electric current, current-reversing means associated therewith, an electromagnet adapted to actuate said current-reversing means, switching means adapted to make connection with successive contacts, electromagnetic mechanism adapted to cause the step-by-step shifting of said switching

means to successive contacts, an electric circuit including the source of current, the switching means and the electromagnet adapted to actuate the current-reversing means, means adapted to close or break said circuit through any predetermined contact, and means whereby the actuation of said means to break said circuit, causes a restoration of said switching means to its normal condition, substantially as described.

44. In combination, a source of electric current, current-reversing means associated therewith, an electromagnet adapted to actuate said current-reversing means, switching means adapted to make connection with successive contacts, electromagnetic mechanism adapted to cause the step-by-step shifting of said switching means to successive contacts, an electric circuit including the source of current, the switching means and the electromagnet adapted to actuate the current-reversing means, a selector-jack connected with each of said contacts, a selector-plug adapted for insertion within any of said jacks, thereby completing said electric circuit through any predetermined contact whereby the electromagnet will be energized to actuate the current-reversing means upon the predetermined step of the switching means, substantially as described.

810,347. GAS-ENGINE. EDWIN F. PORTER and WALTER R. WHITING, Boston, Mass., assignors to American Rotary Engine Company, Boston, Mass., a Corporation of Maine. Filed Mar. 16, 1905. Serial No. 250,268.



Claim.—1. In combination with a cylinder, a piston, two oppositely-rotating crank-shafts, and two pitmen connected to said crank-shafts, of means interposed between said pitmen and piston for loosely connecting the former to the latter to provide lost motion between the said parts.

2. The combination with a cylinder, a piston, two oppositely-rotating crank-shafts, a pitman connected to each crank-shaft, a pitman-block having separate studs or pivots for the pitman, and means for loosely connecting said pitman-block to said piston.

3. The combination with a cylinder, a piston, oppositely-rotating crank-shafts, a separate pitman for each crank-shaft, a pitman-block having separate studs or pivots for each pitman, and a pintle loosely connecting said pitman-block with said piston.

4. The combination with a cylinder, a piston, oppositely-rotating crank-shafts, pitmen connecting said crank-shafts to a member which is loosely mounted on and adapted to change its relative position with said piston.

5. The combination with a cylinder, a piston, oppositely-rotating crank-shafts, pitmen connecting said crank-shafts to a member which is loosely mounted on and adapted to change its relative position with said piston and accommodate itself to any unequal motion of said pitmen.

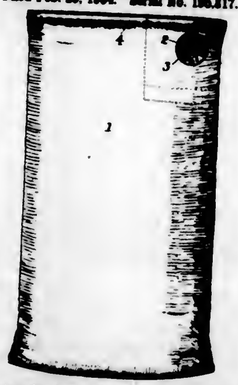
810,348. FURNACE. JACINTO BENEDICT PUGSLEY, Cleveland, Ohio. Original application filed Sept. 23, 1904, Serial No. 225,259. Divided and this application filed Feb. 6, 1905. Serial No. 244,694.

Claim.—1. In furnaces, a combustion-chamber, a bridge-wall, a wheeled grate arranged in the combustion-chamber and reversible to place either end adjacent to the bridge-wall.

2. In a heating plant, a furnace including a combustion-chamber, a turn-table arranged on the floor of the fire-room, and a wheeled grate movable between the combustion-chamber and the turn-table, the latter serving as a means for reversing the position of the grate.

3. In a heating plant, a furnace including a combustion-chamber, a turn-table arranged on the floor of the fire-room and provided with rails, rails leading from the edge of the turn-table to a point within the combustion-chamber, and a wheeled grate arranged on the rails, the turn-table serving as a means for reversing the position of the grate to present either end adjacent to the rear wall of the combustion-chamber.

810,349. VALVE-BAG. JOHN ROGERS, Cleveland, Ohio, assignor to Eaton Valve Bag Company, Cleveland, Ohio, a Corporation of West Virginia. Filed Feb. 29, 1904. Serial No. 196,617.



Claim.—1. A valve-bag, comprising a bag having an opening in the material of its body, and a valve beneath the opening and marginally secured to the body, as set forth.

2. A valve-bag, comprising a bag having an opening in the material of its body, and a valve beneath the opening and marginally secured to the body at different sides of the opening, as set forth.

3. A valve-bag, comprising a bag having an opening in its body, and a valve beneath the opening and marginally secured to the body except at one side of the opening, as set forth.

4. A valve-bag, comprising a bag having an opening in the material of its body, and a valve consisting of a separate piece beneath the opening and marginally secured to the body, as set forth.

5. A valve-bag, comprising a bag having an opening in the material of its body, and a valve consisting of a separate piece beneath the opening and marginally secured to the body at different sides of the opening, as set forth.

6. A valve-bag, comprising a bag having an opening in its body, and a valve consisting of a separate piece beneath the opening and marginally secured to the body except at one side of the opening, as set forth.

7. A valve-bag, comprising a bag having an opening in the material of its body, and a rectangular valve beneath the opening and marginally secured to the body, as set forth.

8. A valve-bag, comprising a bag having an opening in the material of its body, and a rectangular valve beneath the opening and marginally secured to the body at different sides of the opening, as set forth.

9. A valve-bag, comprising a bag having an opening in its body, and a rectangular valve beneath the opening and marginally secured to the body except at one side of the opening, as set forth.

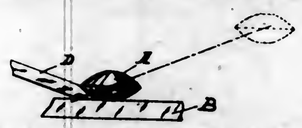
10. A valve-bag, comprising a bag having an opening in its body, and a rectangular valve beneath the opening, said valve secured to the body along its upper end one side edge and pasted to the body along its lower edge, as set forth.

11. A valve-bag having a valve-controlled opening in the material of its body, both ends of said bag being folded and permanently closed, as set forth.

810,350. WITHDRAWN.

810,351. WITHDRAWN.

810,352. GAME-PIECE. FRANK L. SAGNETT, Fredonia, N. Y. Original application filed Apr. 3, 1901, Serial No. 54,696. Divided and this application filed Nov. 26, 1901. Serial No. 83,733.



Claim.—1. A projectable game-piece consisting of a body portion having a materially-restricted base on which said game-piece is adapted to rest and to be glided, and having a maximum diameter in a plane substantially parallel to said base portion and of considerably greater diameter relative thereto, whereby said game-piece is adapted to be projected into the air by impact from suitable means, said game-piece moving substantially in the direction of impact, substantially as described.

2. A projectable game-piece consisting of a solid body portion having a materially-restricted flat base on which said game-piece is adapted to rest and to be guided, and having a maximum diameter in a plane substantially parallel to said base portion and of considerably greater diameter relative thereto, whereby said game-piece is adapted to be projected into the air by impact from suitable means, said game-piece moving substantially in the direction of impact, substantially as described.

3. A projectable game-piece consisting of a solid body portion, having parallel substantially flat portions on which said game-piece may be glided, and having maximum diameters in a plane parallel with and intermediate said flat portions, substantially as described.

4. A projectable game-piece provided with a materially-restricted base on which the same is adapted to rest and to be glided, having a maximum diameter at a distance from the base or surface, the diameter of consecutive sections taken parallel to the central plane containing the maximum diameter, decreasing from said plane to the base, whereby when said game-piece is struck by suitable means at a point between said maximum diameter and base, the said game-piece will be projected into the air without material revolution; substantially as described.

5. A projectable game-piece having a base portion upon which said game-piece is adapted to glide and an outwardly-tapering body portion whereby said game-piece is adapted to be projected into the air by impact from suitable means, said game-piece moving substantially in the direction of impact without material revolution; substantially as described.

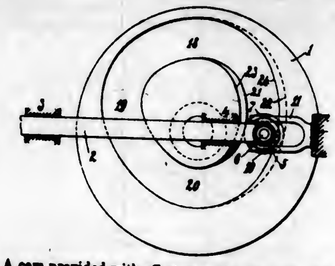
6. In a game apparatus, in combination, a game-piece having a substantially flat base portion upon which said game-piece is adapted to glide, and an outwardly-tapering body portion whereby said game-piece is adapted to be projected into the air, and means for projecting the game-piece, said game-piece moving substantially in the direction of impact without material revolution.

7. In a game apparatus, in combination, a game-piece having a substantially flat base portion upon which said game-piece is adapted to glide, and an outwardly-tapering body portion whereby said game-piece is adapted to be projected into the air, and a cue having means for projecting the game-piece, said game-piece moving substantially in the direction of impact without material revolution.

8. In a game apparatus, in combination, a game-piece having a substantially flat base portion upon which said game-piece is adapted to glide, and an outwardly-tapering body portion whereby said game-piece is adapted to be projected into the air, and a cue having a beveled end for projecting the game-piece, said game-piece moving substantially in the direction of impact without material revolution.

810,353. VARIABLE CAM. HUGO SALMEN and GUSTAV WALSER, Chemnitz, Germany. Filed Nov. 11, 1904. Serial No. 232,216.

Claim.—1. A cam provided with offset operating-surfaces and intermediate switching-surfaces, offset and coincident with said operating-surfaces, and a member adapted for engagement with said switching-surfaces in passing from one operating-surface to the other.



2. A cam provided with offset operating-surfaces and intermediate switching-surfaces, offset and coincident with said operating-surfaces, all of said surfaces terminating in a coincident surface, and a member adapted for engagement with said switching-surfaces in passing from one operating-surface to the other.

3. A closed cam provided with offset operating-grooves and an intermediate switching-groove, offset and coincident with the operating-grooves and relatively enlarged with respect thereto, and a roller loosely coöperating with said intermediate groove in passing from one operating-groove to the other.

810,354. HOSE-COUPLING. MICHAEL L. SCANLON, JOHN S. SCANLON, and ALLEN A. ARNOLD, Galion, Ohio; said Michael L. Scanlon and John S. Scanlon assignors of one-fourth of their right to Mary B. Scanlon, Galion, Ohio. Filed Apr. 27, 1905. Serial No. 257,603.

Claim.—1. The combination in a coupling, of abutting male members, a ring on one of said members having shoulders oppositely located thereon, a spring on this member, located in rear of the ring and confined in place by said ring and a shoulder on this member, a sleeve on the same member, supported by tension of the spring, an inner flange on the sleeve adapted for engagement with the spring, extensions on the sleeve, having inwardly-projecting edges, a similar sleeve, having adjustment on the other male member of the coupling, and extensions on the latter sleeve, having inwardly-projecting edges, the said sleeve extensions being spaced apart adapted to fit together, substantially as described.

2. The combination in a coupling, of male members, sleeves on the male members having separating adjustment and one thereof being adapted to be yieldingly held under tension, extensions on the abutting ends of the sleeves, having inwardly-projecting edges, a spring confined on one male member, supporting its sleeve under tension, and a ring on one male member having shoulders adapted for locking engagement with the inner projecting edges of extensions on a sleeve supported on the other male member, substantially as described.

3. The combination in a coupling, of male members, sleeves on the male members, having separating adjustment and one thereof being adapted to be yieldingly held under tension, extensions on the abutting ends of the sleeves, having inwardly-projecting edges, a spring confined on one male member, supporting its sleeve under tension, a ring on one male member having shoulders adapted for locking engagement with the inner projecting edges of the extensions on the other male member, adjustable jam-collars on one male member, a rib on the other male member, and means on the sleeve carried by said member adapted for engagement with the rib, when the sleeve is adjusted, substantially as described.

810,355. ORTHOPEDIC APPLIANCE FOR CURING KNOCK-KNEES, &c. OSKAR SEBELIEWSKI, Vienna, Austria-Hungary. Filed May 27, 1903. Serial No. 159,627.

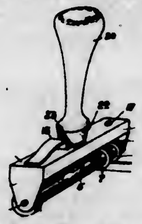
Claim.—1. In an orthopedic appliance, the combination of a

shoe member, a brace secured to the shoe member and extending upward along the leg, means for securing the brace to the leg at its upper end, and a heel member pivotally secured to the rear of the shoe and arranged to swing upward from a position normally parallel with the shoe-bottom, and on a pivotal line located at one side of the heel.

2. In an orthopedic appliance, the combination with a shoe of a collapsible heel member having its bottom member pivoted along one of the lateral sides to swing upward from a position parallel with the shoe-bottom, a spring tending to normally retain the bottom member in a parallel position, and a jointed brace secured to the shoe for attachment to the leg of the wearer.

3. In an orthopedic appliance, the combination of a shoe, an upright plate rigidly secured along one of the lateral sides and extending downward, a plate pivotally connected with the lower edge of the upright plate, a plate secured to the bottom of said pivoted plate, a spring tending to retain the latter plates parallel with the bottom of the shoe, a flexible member connecting the lower plates with the shoe-bottom and inclosing the spring member and upright plate, a jointed brace secured to the shoe and extending upward, and a strap arranged to secure the upper end of the brace to the leg.

810,356. RULING DEVICE. DONALD P. SHANKWILER, South Bend, Ind. Filed Apr. 15, 1905. Serial No. 255,794.



Claim.—1. In a ruling device, a frame having a roller journaled therein, a ruling-disk carried by the roller, a compartment in the frame, an inking-pad in the compartment normally held from engagement with the ruling-disk, and means accessible from the top of the frame for engaging said pad with the ruling-disk.

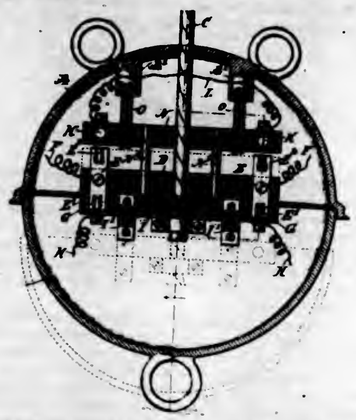
2. In a ruling device, a frame, a compartment in the frame, ruling-disks journaled in the frame and projecting into said compartment, inking-pads mounted in the compartment, one of which is normally held in contact with one of the ruling-disks, and a spring-arm secured to the frame and projecting above the same and adapted to be pressed to engage the other pad with the other ruling-disk.

3. In a ruling device, the combination, with a frame having ruling-disks journaled therein, and inking-pads mounted in the frame above said disks, of a spring-arm secured beneath the frame and carrying one of said inking-pads and also having a portion projecting above the frame to form a thumb-piece for engaging the pad with a ruling-disk.

810,357. ELECTRIC SWITCH FOR STREET ARC-LAMPS, &c. PIERRE H. F. STERN, New York, N. Y., assignor, by direct and mesne assignments, of one-third to David H. Arnold, one-third to Leroy H. Haskins, and one-third to William T. Lambert, all of New York, N. Y. Filed Feb. 10, 1905. Serial No. 245,647.

Claim.—1. An electric switch for arc-lamps, chandeliers, and the like, comprising fixed line-contacts connected with the line, a block moving with the lamp and carrying lamp-contacts connected with the lamp-circuit, and adapted to engage the lower ends of the line-contacts, and a movable block carrying auxiliary contacts, electrically connected with each other, the said block being controlled by the movement of the block carrying the lamp-contacts, the said auxiliary contacts being adapted to engage the upper ends of the line-contacts.

2. An electric switch for arc-lamps, chandeliers, and the like, comprising a fixed block, sets of contacts secured on said block and connected with the line, the contacts projecting beyond the bottom and top of the block, a block movable with the lamp and carrying lamp-contacts connected with the lamp-circuit and adapted to engage the lower projecting ends of said line-contacts, and a movable block carrying auxiliary contacts, adapted to engage the upper ends of said line-contacts, the movement of said block carrying the auxiliary contacts being controlled by the block carrying the lamp-contacts, the said auxiliary contacts being normally out of engagement with the line-contacts.



3. An electric switch for arc-lamps, chandeliers, and the like, comprising a fixed block, sets of contacts secured on said block and connected with the line, the contacts projecting beyond the bottom and top of the block, a block moving with the lamp and carrying contacts connected with the lamp-circuits and adapted to engage the lower projecting ends of the said line-contacts, a block having guided movement and controlled by the movement of the block carrying the lamp-contacts, the said block carrying auxiliary contacts adapted to engage the upper projecting ends of said line-contacts, the auxiliary contacts moving in contact with the line-contacts immediately previous to the lamp-contacts moving out of engagement with the line-contacts.

4. An electric switch for arc-lamps, chandeliers, and the like, comprising a fixed block of insulating material, sets of contact-plates secured on said block and connected with the line, the contact-plates projecting beyond the bottom and top of the block, a block of insulating material moving with the lamp and carrying contact-pins connected with the lamp-circuit, and adapted to engage the lower projecting ends of said line-contact plates, a block of insulating material provided with guide-pins arranged to slide in bearings in the said fixed block and adapted to rest on the upper surface of the block carrying the lamp-contact pins, the said block carrying auxiliary contact-pins electrically connected and adapted to engage the upper projecting ends of said line-contact plates, the movement of the block carrying the auxiliary contact-pins being controlled by the movement of the block carrying the lamp-contact pins, the said auxiliary contact-pins moving in contact with the line-contact plates immediately previous to the lamp-contact pins moving out of engagement with the line-contact plates, and the said auxiliary contact-pins being moved out of engagement with the line-contact plates after the lamp-contact pins have moved in engagement with the line-contact plates.

5. An electric switch for arc-lamps, chandeliers and the like, comprising a hanger made in two parts, of which one is fixed and the other movable toward and from the fixed hanger part, the movable hanger part carrying the lamp, double line-contacts fixed in the said fixed hanger part and connected with the line, a spring-pressed block carrying auxiliary contacts for engaging the line-contacts at one side, and a block fixed in the movable hanger part and carrying the lamp-contacts connected with the lamp-circuit, the said lamp-contact block engaging the said spring-pressed block, to move the latter against the tension of its springs.

6. An electric switch for arc-lamps, chandeliers and the like, comprising a hanger made in two parts, of which one is fixed and the other movable toward and from the fixed hanger part, the movable hanger part carrying the lamp, double line-contacts fixed in the said fixed hanger part and connected with the line, a spring-pressed block carrying auxiliary contacts for engaging the line-contacts at one side, the said block having guide-pins slidable in bearings on the said hanger part, and a block fixed in the movable hanger part and carrying the lamp-contacts connected with the lamp-circuit, the said lamp-contact block being adapted to engage the said guide-pins, to move the spring-pressed block against the tension of its springs.

7. An electric switch for arc-lamps, chandeliers, and the like, comprising fixed line-contacts consisting of sets of contact-plates connected with the line, contact-pins moving with the lamp and connected with the lamp-circuit, the said contact-pins being adapted to engage the line-contact plates, and auxiliary contact-pins controlled by the movement of the lamp-contacts and adapted to engage the said line-contact plates.

8. An electric switch for arc-lamps, chandeliers, and the like, comprising a hanger made in two parts, one part being fixed and the other movable toward and from the fixed part, the movable hanger part carrying the lamp, a block secured to the upper or fixed part of the hanger, sets of contact-plates secured at each end of said block and having their ends projecting respectively beyond the bottom and top of the block, the said contact-plates being connected with the line-wires, a block secured to the movable hanger part, contact-pins carried by said block and connected with the lamp-circuit, the said contact-pins being adapted to contact with the lower ends of said line-contact plates when the movable hanger part is in raised or normal position, and a spring-pressed block carrying contact-pins electrically connected with each other and adapted to contact with the upper ends of said contact-plates when the movable hanger part is in the lowered position.

810,358. RAILWAY-TRACK JACK. JOHN STEWART, New Glasgow, Canada. Filed Aug. 15, 1904. Renewed Dec. 13, 1905. Serial No. 292,186.

Claim.—1. The stand provided with the pocket I adapted to inclose link E and formed with the fulcrum F properly adjacent to said link.

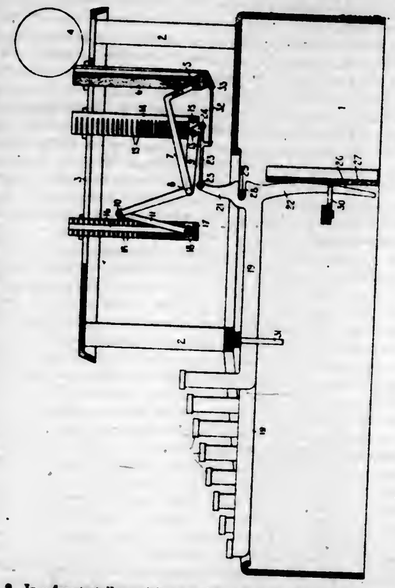
2. The stand provided with the fulcrum F and the removable wear-plate F'.

3. The combination with the jam-nuts of the filling-ring and the link E interposed between said nuts, and operating as set forth.

4. The stand provided with the hook J in combination with the jam-nuts as set forth.

810,359. TYPE-WRITING MACHINE. BURNHAM C. STRICKLAND, Elizabeth, N. J., assignor to Union Typewriter Company, Jersey City, N. J., a Corporation of New Jersey. Filed Apr. 6, 1903. Serial No. 151,293.

Claim.—1. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars; a series of key-bearing bell-cranks connected thereto; said bell-cranks comprising forwardly-extending key-bearing arms and downwardly-extending arms having elongated treads, and the points of said levers which are connected to said type-bars having a forward and backward movement; a fulcrum-plate upon which said treads have a rocker motion; said fulcrum-plate standing on edge; and a bar engaged by all of said treads for supporting the same against downward or upward displacement.



2. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars; a series of levers connected to said type-bars and comprising forwardly-extending key-bearing arms and downwardly-extending arms having elongated curved treads, notches in the latter arms, a fixed transverse supporting-bar engaged by said notches, and an upright plate upon which said treads have a rocker motion.

3. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars; a series of T-shaped levers comprising forwardly-extending key-bearing arms, upwardly-extending arms, and downwardly-extending arms having elongated treads; links extending forwardly between said type-bars and said upwardly-extending arms; notches in said levers; a fixed transverse bar engaged by said notches for preventing upward or downward displacement of said levers at their rear ends; and a fulcrum-plate upon which said downwardly-extending arms have a rocker motion.

4. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars; a series of T-shaped levers comprising forwardly-extending key-bearing arms, upwardly-extending arms, and downwardly-extending arms having elongated treads; links extending forwardly between said type-bars and said upwardly-extending arms; notches in said downwardly-extending arms; a fulcrum-plate upon which the latter arms have a rocker motion; and a fixed transverse bar mounted upon said plate between the upper and lower edges thereof and engaged by said notches for preventing upward or downward displacement of said levers at their rear ends.

5. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars; a series of T-shaped levers comprising forwardly-extending key-bearing arms, upwardly-extending arms, and downwardly-extending arms having elongated treads; links extending forwardly between said type-bars and said upwardly-extending arms; notches in said levers; a fixed transverse bar engaged by said notches for preventing upward or downward displacement of said levers at their rear ends; a fulcrum-plate upon which said downwardly-extending arms have a rocker motion; and returning-springs attached to said links and extending to a fixed support.

6. In a front-strike writing-machine, the combination of a system of rearwardly-striking type-bars; a system of levers comprising forwardly-extending key-bearing arms, downwardly-extending arms having elongated treads, and upwardly-extending arms connected to the type-bars; and a bearing-plate upon which said treads have a rocker motion; said upwardly-extending arms being shortest at the

middle of the system and being progressively longer from the middle to the sides of the system, and said downwardly-extending arms being longest at the middle of the system and being progressively shorter from the middle to the sides of the system.

7. In a front-strike writing-machine, the combination of a system of rearwardly-striking type-bars, a system of levers comprising forwardly-extending key-bearing arms, downwardly-extending arms having elongated treads, and upwardly-extending arms, a bearing-plate upon which said treads have a rocker motion; said upwardly-extending arms being shortest at the middle of the system and being progressively longer from the middle to the sides of the system, and said downwardly-extending arms being longest at the middle of the system and being progressively shorter from the middle to the sides of the system; links extending forwardly between said type-bars and said upwardly-extending arms; returning-springs attached to said links; and means for preventing upward or downward displacement of said downwardly-extending arms.

8. In a front-strike writing-machine, the combination of a series of radial links, a series of rearwardly-striking type-carriers pivoted upon the free ends of said links; a second series of radial links upon which said type-carriers are also pivoted; a series of T-levers comprising forwardly-extending key-bearing arms, upwardly-extending arms, and downwardly-extending arms; connections extending forwardly between one of said sets of radial links and said upwardly-extending arms; elongated treads formed on said downwardly-extending arms; a plate upon which said treads have a rocker motion; and a transverse bar for supporting the rear ends of said levers.

9. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars; a series of T-shaped levers comprising forwardly-extending key-bearing arms, upwardly-extending arms, and downwardly-extending arms having elongated treads; links extending forwardly between said type-bars and said upwardly-extending arms; notches in said downwardly-extending arms; a fulcrum-plate upon which the latter arms have a rocker motion; and a fixed transverse bar mounted upon said plate between the upper and lower edges thereof and engaged by said notches for preventing upward or downward displacement of said levers at their rear ends; said forwardly-extending arms being attached to said cross-arms at points above said notches.

10. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of key-bearing levers, a series of links connecting said type-bars to said levers; said levers having a series of upwardly-extending arms to whose upper ends said links are attached, said arms being shortest at the middle of the system, and increasing progressively in length from the middle to the sides of the system, and means for affording a change of fulcrum of said levers as they are depressed.

11. The combination with a series of type-bars of a series of T-shaped key-levers, a link connecting each type-bar to one arm of one of said levers, a key carried by another arm of said levers, said levers also having at their rear ends downwardly-extending arms provided with suitable bearings; said downwardly-extending arms being longest at the middle of the system and decreasing progressively in length from the middle to the sides of the system, and a co-operating bearing for the downwardly-extending arms of said levers.

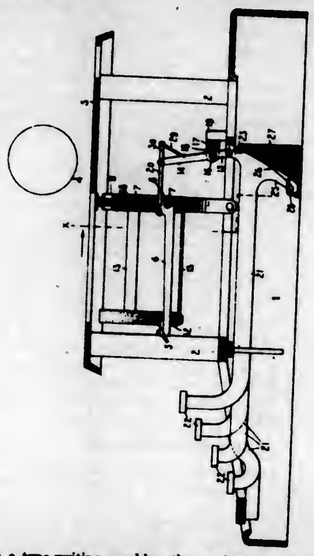
12. In a type-writing machine, the combination of a front-strike jointed type-bar, and a key-lever operatively connected to said type-bar, said key-lever having a downwardly-extending arm and a bearing on which said arm rocks and changes its fulcrum.

13. In a type-writing machine, the combination of a series of segmentally-arranged type-bars, key-levers operatively connected thereto and having rocker-arms that afford a change of leverage as the key-levers are depressed, the rocker-arms at the center of the system having a greater extent of rocking movement on their bearings than those at the sides of the system.

14. In a type-writing machine, the combination of a series of segmentally-arranged type-bars, key-levers having connecting-arms of different lengths operatively connected to the type-bars and having rocker-arms that afford a change of leverage as the key-levers are depressed, the rocker-arms for the key-levers with the shorter connecting-arms having greater extents of rocking movement on their bearings than the rocker-arms for the key-levers having the longer connecting-arms.

810,360. TYPE-WRITING MACHINE. SUMNER G. SHERMAN, Hoboken, N. J., assignor to Union Typewriter Company, Jersey City, N. J., a Corporation of New Jersey. Filed Apr. 6, 1903. Serial No. 151,592.

Claim.—1. In a type-writing machine, the combination of a series of type-bars, a series of sublevers connected thereto, a series of key-bearing forwardly-extending levers pivoted at their rear ends to said sublevers, angular arms on the rear ends of said key-bearing levers, said angular arms being provided with elongated treads, and a support upon which said treads have a rocker motion in an up and down direction.



2. In a type-writing machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding sublevers connected thereto, a series of key-bearing forwardly-extending levers pivoted at their rear ends to said upstanding levers, angular arms on the rear ends of said key-levers, said angular arms being provided with elongated treads, and a support upon which said treads have a rocker motion.

3. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of key-bearing levers extending forwardly beneath the type-bars, upwardly-extending arms on said key-levers, downwardly-extending arms on said key-levers, a set of sublevers connected to one set of said arms and also connected to the type-bars, elongated treads on the other set of said arms, and a support along which said treads have a rocker motion.

4. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of key-bearing levers extending forwardly and each having ramifications at its rear end, a set of sublevers connected to one set of ramifications and also connected to the type-bars, elongated treads formed on the other set of ramifications, and a support upon which said treads have a rocker motion.

5. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding levers in rear of the type-bars, a series of key-operated levers each having ramifications at their rear ends, one set of ramifications being pivoted directly to the lower ends of said upstanding levers, and the other set of ramifications having elongated treads, and bearings along which said treads have a rocker motion.

6. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding levers of the first order mounted in rear of said type-bars, links connecting said levers to said type-bars, T-shaped levers including forwardly-extending key-bearing arms, upwardly-extending arms which are pivoted directly to the lower arms of said upstanding levers, and downwardly-extending arms having elongated treads; and a support upon which said treads have a rocker motion.

7. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding levers of the first order connected to said type-bars, and forwardly-extending key-levers pivoted to the lower arms and below the fulcrums of said upstanding levers; said key-levers having elongated treads; and a fixed support along which said treads have a rocker motion.

8. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding sublevers in rear of said type-bars, each of said levers being fulcrumed between its ends, links connecting the upper ends of said levers to said type-bars, forwardly-extending T-shaped key-levers pivoted at one set of their cross-arms to the depending arms of said upstanding sublevers, elongated treads formed upon the other set of cross-arms, and means for supporting and guiding said treads during the movements of said key-levers.

9. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of T-shaped key-levers, keys upon one set of arms of said key-levers, elongated treads upon another set of arms of said key-levers, a support along which said fulcrums have a rocker motion, and connections between the third set of arms of said key-levers and said type-bars; said connections including a set of sublevers.

10. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of T-shaped key-levers, keys upon one set of arms of said key-levers, elongated treads upon another set of arms of said key-levers, a support along which said fulcrums have a rocker motion, and connections between the third set of arms of said key-levers and said type-bars; said connections including both a set of sublevers to which the last-mentioned key-lever arms are directly pivoted, and links extending from said sublevers to the type-bars.

11. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding levers of the first order mounted in rear of said type-bars, links connecting said levers to said type-bars, T-shaped levers including forwardly-extending key-bearing arms, upwardly-extending arms which are pivoted directly to the lower arms of said upstanding levers, and downwardly-extending arms having elongated treads, and a support upon which said treads may have a rocker motion, said system of upstanding levers being less in width than said system of key-levers at the keyboard, and said system of key-levers converging rearwardly.

12. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding levers of the first order mounted in rear of said type-bars, links connecting said levers to said type-bars, T-shaped levers including forwardly-extending key-bearing arms, upwardly-extending arms which are pivoted directly to the lower arms of said upstanding levers, and downwardly-extending arms having elongated treads; a support upon which said treads have a rocker motion; and a single transverse fulcrum-rod upon which said upstanding levers are pivoted; the upwardly-extending arms of said sublevers being shortest at the middle of the system and of progressively-increasing length from the middle to the sides of the system, and their downwardly-extending arms being of correspondingly-increasing lengths.

13. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding levers of the first order mounted in rear of said type-bars, links connecting said levers to said type-bars, T-shaped levers including forwardly-extending key-bearing arms, upwardly-extending arms which are pivoted directly to the lower arms of said upstanding levers, and downwardly-extending arms having elongated treads; a support upon which said treads may have a rocker motion; and a single transverse fulcrum-rod upon which said upstanding levers are pivoted; the upwardly-extending arms of said sublevers being shortest at the middle of the system and of progressively-increasing length from the middle to the sides of the system, and their downwardly-extending arms being of correspondingly-increasing lengths, and the upwardly extending arms on the key-levers being longest at the middle of the system and progressively decreasing in length from the middle to the sides of the system.

14. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of sublevers connected to the type-bars, and a series of key-bearing levers pivoted to the sublevers; one of said sets of levers having arms provided with elongated treads, the said sublevers vibrating on fixed pivots arranged above the key-levers; and a fixed support upon which said treads have a rocker motion during the type-bar movements.

15. In a type-writing machine, the combination with a series of rearwardly-striking type-bars, of a series of upstanding levers of the first order connected to said type-bars; said levers being fulcrumed in a transverse horizontal line, their upwardly-extending arms being shortest in the middle of the system and progressively increasing in length from the middle to the sides of the system, and their downwardly-extending arms being of correspondingly-increasing lengths but shorter than the upwardly-extending arms; a system of key-levers connected to said upstanding levers and having elongated treads; and a support upon which said treads have a rocker motion.

16. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding levers of the first order mounted in rear of said type-bars, links connecting said levers to said type-bars, T-shaped levers including forwardly-extending key-bearing arms, upwardly-extending arms which are pivoted directly to the lower arms of said upstanding levers, and downwardly-extending arms having elongated treads; a support upon which said treads have a rocker motion; and a system of returning-springs connected to said upstanding levers.

17. In a type-writing machine, the combination of a series of types, a series of type-operating arms, a series of T-shaped levers pivoted at one set of their cross-arms to said type-operating arms, elongated treads formed upon the other set of said cross-arms, a fixed support having an elongated transverse tread along which said treads on the levers have a rocker motion to effect an automatic change of leverage, and a series of keys carried by the stem-like arms of the T-shaped levers.

18. In a type-writing machine, the combination of a series of type-bars, a series of key-bearing T-shaped levers, a series of sublevers to which said key-levers are pivoted at one set of their cross-arms, elongated treads formed upon another set of the arms of said T-levers, a support along which said treads may have a rocker motion, and a set of returning-springs.

19. In a type-writing machine, the combination of a series of type-bars, a series of key-bearing T-shaped levers, a series of sublevers to which said key-bearing levers are pivoted at one set of their cross-arms, elongated treads formed upon the other set of cross-arms of said T-levers, and a support along which said treads have a rocker motion; said treads being materially longer than the cross-arms that are pivoted to the sublevers.

20. In a type-writing machine, the combination of a series of type-bars, a series of keys, and two sets of levers between said keys and said type-bars; one set of said levers being pivoted to the other, and one set of said levers consisting of bell-cranks which carry said keys, and having arms provided with elongated treads; and a fixed support upon which said treads have a rocker motion.

21. In a type-writing machine, the combination of a series of type-bars and a series of key-bearing bell-cranks connected thereto; the fulcrum-arms of said bell-cranks having elongated treads; and arms upon which said fulcrum-arms are pivoted and whereby they are supported against endwise displacement: and a support along which said treads have a rocker motion.

22. In a type-writing machine, the combination of a series of type-bars; a series of T-shaped levers comprising forwardly-extending key-bearing arms, upwardly-extending arms, and downwardly-extending arms having elongated treads; a support along which said treads have a rocker motion; and a series of sublevers between said upwardly-extending arms and said type-bars.

23. In a type-writing machine, the combination of a type-bar and a key-operated lever connected thereto; said lever having an elongated curved tread portion; and a support along which said tread has a rocker motion; said support being curved in the direction of the length of said tread.

24. In a type-writing machine, the combination of a type-bar and key-operated lever connected thereto; said lever having an elongated curved tread portion; and a support along which said tread has a rocker motion; said support being curved in the direction of the length of said tread, the curve of the support nearly matching but having a different radius from the curve of the tread.

25. In a type-writing machine, the combination of a type-bar and a key-operated lever connected thereto; said lever having an elongated curved tread portion; and a support along which said tread has a rocker motion; said support being curved in the direction of the length of said tread, the tread curve being convex, and the support curve being concave and of greater radius than the tread curve.

26. In a type-writing machine, the combination with a type-bar of a key-lever connected thereto and having a downwardly and forwardly inclined angle-arm which is provided with an elongated tread; and a downwardly and forwardly inclined support along which said tread has a rocker motion; at least one of said tread and support elements being curved.

27. In a type-writing machine, the combination with a type-bar of a key-lever connected thereto and having a downwardly and forwardly inclined arm which is provided with an elongated convexly-curved tread; and a downwardly and forwardly inclined support along which said tread has a rocker motion.

28. In a type-writing machine, the combination with a type-bar

middle of the system and being progressively longer from the middle to the sides of the system, and said downwardly-extending arms being longest at the middle of the system and being progressively shorter from the middle to the sides of the system.

7. In a front-strike writing-machine, the combination of a system of rearwardly-striking type-bars, a system of levers comprising forwardly-extending key-bearing arms, downwardly-extending arms having elongated treads, and upwardly-extending arms, a bearing-plate upon which said treads have a rocker motion; said upwardly-extending arms being shortest at the middle of the system and being progressively longer from the middle to the sides of the system, and said downwardly-extending arms being longest at the middle of the system and being progressively shorter from the middle to the sides of the system; links extending forwardly between said type-bars and said upwardly-extending arms; returning-springs attached to said links; and means for preventing upward or downward displacement of said downwardly-extending arms.

8. In a front-strike writing-machine, the combination of a series of radial links, a series of rearwardly-striking type-carriers pivoted upon the free ends of said links; a second series of radial links upon which said type-carriers are also pivoted; a series of T-levers comprising forwardly-extending key-bearing arms, upwardly-extending arms, and downwardly-extending arms; connections extending forwardly between one of said sets of radial links and said upwardly-extending arms; elongated treads formed on said downwardly-extending arms; a plate upon which said treads have a rocker motion; and a transverse bar for supporting the rear ends of said levers.

9. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars; a series of T-shaped levers comprising forwardly-extending key-bearing arms, upwardly-extending arms, and downwardly-extending arms having elongated treads; links extending forwardly between said type-bars and said upwardly-extending arms; notches in said downwardly-extending arms; a fulcrum-plate upon which the latter arms have a rocker motion; and a fixed transverse bar mounted upon said plate between the upper and lower edges thereof and engaged by said notches for preventing upward or downward displacement of said levers at their rear ends; said forwardly-extending arms being attached to said cross-arms at points above said notches.

10. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of key-bearing levers, a series of links connecting said type-bars to said levers; said levers having a series of upwardly-extending arms to whose upper ends said links are attached, said arms being shortest at the middle of the system, and increasing progressively in length from the middle to the sides of the system, and means for affording a change of fulcrum of said levers as they are depressed.

11. The combination with a series of type-bars of a series of T-shaped key-levers, a link connecting each type-bar to one arm of one of said levers, a key carried by another arm of said levers, said levers also having at their rear ends downwardly-extending arms provided with suitable bearings; said downwardly-extending arms being longest at the middle of the system and decreasing progressively in length from the middle to the sides of the system, and a coöperating bearing for the downwardly-extending arms of said levers.

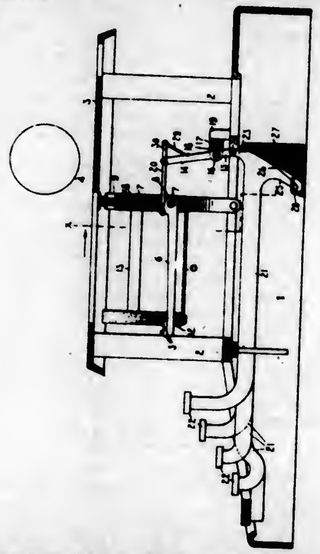
12. In a type-writing machine, the combination of a front-strike jointed type-bar, and a key-lever operatively connected to said type-bar, said key-lever having a downwardly-extending arm and a bearing on which said arm rocks and changes its fulcrum.

13. In a type-writing machine, the combination of a series of segmentally-arranged type-bars, key-levers operatively connected thereto and having rocker-arms that afford a change of leverage as the key-levers are depressed, the rocker-arms at the center of the system having a greater extent of rocking movement on their bearings than those at the sides of the system.

14. In a type-writing machine, the combination of a series of segmentally-arranged type-bars, key-levers having connecting-arms of different lengths operatively connected to the type-bars and having rocker-arms that afford a change of leverage as the key-levers are depressed, the rocker-arms for the key-levers with the shorter connecting-arms having greater extents of rocking movement on their bearings than the rocker-arms for the key-levers having the longer connecting-arms.

810,860. TYPE-WRITING MACHINE. DURHAM C. STOCKETT, Elizabeth, N. J., assignor to Union Typewriter Company, Jersey City, N. J., a Corporation of New Jersey. Filed Apr. 6, 1903. Serial No. 151,593.

Claim.—1. In a type-writing machine, the combination of a series of type-bars, a series of sublevers connected thereto, a series of key-bearing forwardly-extending levers pivoted at their rear ends to said sublevers, angular arms on the rear ends of said key-bearing levers, said angular arms being provided with elongated treads, and a support upon which said treads have a rocker motion in an up and down direction.



2. In a type-writing machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding sublevers connected thereto, a series of key-bearing forwardly-extending levers pivoted at their rear ends to said upstanding levers, angular arms on the rear ends of said key-levers, said angular arms being provided with elongated treads, and a support upon which said treads have a rocker motion.

3. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of key-bearing levers extending forwardly beneath the type-bars, upwardly-extending arms on said key-levers, downwardly-extending arms on said key-levers, a set of sublevers connected to one set of said arms and also connected to the type-bars, elongated treads on the other set of said arms, and a support along which said treads have a rocker motion.

4. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of key-bearing levers extending forwardly and each having ramifications at its rear end, a set of sublevers connected to one set of ramifications and also connected to the type-bars, elongated treads formed on the other set of ramifications, and a support upon which said treads have a rocker motion.

5. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding levers in rear of the type-bars, a series of key-operated levers each having ramifications at their rear ends, one set of ramifications being pivoted directly to the lower ends of said upstanding levers, and the other set of ramifications having elongated treads, and bearings along which said treads have a rocker motion.

6. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding levers of the first order mounted in rear of said type-bars, links connecting said levers to said type-bars, T-shaped levers including forwardly-extending key-bearing arms, upwardly-extending arms which are pivoted directly to the lower arms of said upstanding levers, and downwardly-extending arms having elongated treads; and a support upon which said treads have a rocker motion.

7. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding levers of the first order connected to said type-bars, and forwardly-extending key-levers pivoted to the lower arms and below the fulcrums of said upstanding levers; said key-levers having elongated treads; and a fixed support along which said treads have a rocker motion.

8. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding sublevers in rear of said type-bars, each of said levers being fulcrumed between its ends, links connecting the upper ends of said levers to said type-bars, forwardly-extending T-shaped key-levers pivoted at one set of their cross-arms to the depending arms of said upstanding sublevers, elongated treads formed upon the other set of cross-arms, and means for supporting and guiding said treads during the movements of said key-levers.

9. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of T-shaped key-levers, keys upon one set of arms of said key-levers, elongated treads upon another set of arms of said key-levers, a support along which said fulcrums have a rocker motion, and connections between the third set of arms of said key-levers and said type-bars; said connections including a set of sublevers.

10. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of T-shaped key-levers, keys upon one set of arms of said key-levers, elongated treads upon another set of arms of said key-levers, a support along which said fulcrums have a rocker motion, and connections between the third set of arms of said key-levers and said type-bars; said connections including both a set of sublevers to which the last-mentioned key-lever arms are directly pivoted, and links extending from said sublevers to the type-bars.

11. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding levers of the first order mounted in rear of said type-bars, links connecting said levers to said type-bars, T-shaped levers including forwardly-extending key-bearing arms, upwardly-extending arms which are pivoted directly to the lower arms of said upstanding levers, and downwardly-extending arms having elongated treads, and a support upon which said treads may have a rocker motion, said system of upstanding levers being less in width than said system of key-levers at the keyboard, and said system of key-levers converging rearwardly.

12. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding levers of the first order mounted in rear of said type-bars, links connecting said levers to said type-bars, T-shaped levers including forwardly-extending key-bearing arms, upwardly-extending arms which are pivoted directly to the lower arms of said upstanding levers, and downwardly-extending arms having elongated treads; a support upon which said treads have a rocker motion; and a single transverse fulcrum-rod upon which said upstanding levers are pivoted; the upwardly-extending arms of said sublevers being shortest at the middle of the system and of progressively-increasing length from the middle to the sides of the system, and their downwardly-extending arms being of correspondingly-increasing lengths.

13. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding levers of the first order mounted in rear of said type-bars, links connecting said levers to said type-bars, T-shaped levers including forwardly-extending key-bearing arms, upwardly-extending arms which are pivoted directly to the lower arms of said upstanding levers, and downwardly-extending arms having elongated treads; a support upon which said treads may have a rocker motion; and a single transverse fulcrum-rod upon which said upstanding levers are pivoted; the upwardly-extending arms of said sublevers being shortest at the middle of the system and of progressively-increasing length from the middle to the sides of the system, and their downwardly-extending arms being of correspondingly-increasing lengths, and the upwardly extending arms on the key-levers being longest at the middle of the system and progressively decreasing in length from the middle to the sides of the system.

14. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of sublevers connected to the type-bars, and a series of key-bearing levers pivoted to the sublevers; one of said sets of levers having arms provided with elongated treads, the said sublevers vibrating on fixed pivots arranged above the key-levers; and a fixed support upon which said treads have a rocker motion during the type-bar movements.

15. In a type-writing machine, the combination with a series of rearwardly-striking type-bars, of a series of upstanding levers of the first order connected to said type-bars; said levers being fulcrumed in a transverse horizontal line, their upwardly-extending arms being shortest in the middle of the system and progressively increasing in length from the middle to the sides of the system, and their downwardly-extending arms being of correspondingly-increasing lengths but shorter than the upwardly-extending arms; a system of key-levers connected to said upstanding levers and having elongated treads; and a support upon which said treads have a rocker motion.

16. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of upstanding levers of the first order mounted in rear of said type-bars, links connecting said levers to said type-bars, T-shaped levers including forwardly-extending key-bearing arms, upwardly-extending arms which are pivoted directly to the lower arms of said upstanding levers, and downwardly-extending arms having elongated treads; a support upon which said treads have a rocker motion; and a system of returning-springs connected to said upstanding levers.

17. In a type-writing machine, the combination of a series of types, a series of type-operating arms, a series of T-shaped levers pivoted at one set of their cross-arms to said type-operating arms, elongated treads formed upon the other set of said cross-arms, a fixed support having an elongated transverse tread along which said treads on the levers have a rocker motion to effect an automatic change of leverage, and a series of keys carried by the stem-like arms of the T-shaped levers.

18. In a type-writing machine, the combination of a series of type-bars, a series of key-bearing T-shaped levers, a series of sublevers to which said key-levers are pivoted at one set of their cross-arms, elongated treads formed upon another set of the arms of said T-levers, a support along which said treads may have a rocker motion, and a set of returning-springs.

19. In a type-writing machine, the combination of a series of type-bars, a series of key-bearing T-shaped levers, a series of sublevers to which said key-bearing levers are pivoted at one set of their cross-arms, elongated treads formed upon the other set of cross-arms of said T-levers, and a support along which said treads have a rocker motion; said treads being materially longer than the cross-arms that are pivoted to the sublevers.

20. In a type-writing machine, the combination of a series of type-bars, a series of keys, and two sets of levers between said keys and said type-bars; one set of said levers being pivoted to the other, and one set of said levers consisting of bell-cranks which carry said keys, and having arms provided with elongated treads; and a fixed support upon which said treads have a rocker motion.

21. In a type-writing machine, the combination of a series of type-bars and a series of key-bearing bell-cranks connected thereto; the fulcrum-arms of said bell-cranks having elongated treads; and arms upon which said fulcrum-arms are pivoted and whereby they are supported against endwise displacement; and a support along which said treads have a rocker motion.

22. In a type-writing machine, the combination of a series of type-bars; a series of T-shaped levers comprising forwardly-extending key-bearing arms, upwardly-extending arms, and downwardly-extending arms having elongated treads; a support along which said treads have a rocker motion; and a series of sublevers between said upwardly-extending arms and said type-bars.

23. In a type-writing machine, the combination of a type-bar and a key-operated lever connected thereto; said lever having an elongated curved tread portion; and a support along which said tread has a rocker motion; said support being curved in the direction of the length of said tread.

24. In a type-writing machine, the combination of a type-bar and key-operated lever connected thereto; said lever having an elongated curved tread portion; and a support along which said tread has a rocker motion; said support being curved in the direction of the length of said tread, the curve of the support nearly matching but having a different radius from the curve of the tread.

25. In a type-writing machine, the combination of a type-bar and a key-operated lever connected thereto; said lever having an elongated curved tread portion; and a support along which said tread has a rocker motion; said support being curved in the direction of the length of said tread, the tread curve being convex, and the support curve being concave and of greater radius than the tread curve.

26. In a type-writing machine, the combination with a type-bar of a key-lever connected thereto and having a downwardly and forwardly inclined angle-arm which is provided with an elongated tread; and a downwardly and forwardly inclined support along which said tread has a rocker motion; at least one of said tread and support elements being curved.

27. In a type-writing machine, the combination with a type-bar of a key-lever connected thereto and having a downwardly and forwardly inclined arm which is provided with an elongated convexly-curved tread; and a downwardly and forwardly inclined support along which said tread has a rocker motion.

28. In a type-writing machine, the combination with a type-bar

and a key-lever connected thereto and having a downwardly and forwardly inclined arm which is provided with an elongated convexly-curved tread; and a downwardly and forwardly inclined concave support along which said tread has a rocker motion; the curve of the support having greater radius than the curve of the tread.

29. In a type-writing machine, the combination of an upright elongated fulcrum, a member with an upright elongated tread that has a rocking movement on said fulcrum, a key connected to said member, and a type-bar operatively connected to said member.

30. In a type writing machine, the combination of an upright elongated fulcrum, a key-lever with an upright elongated tread that has a rocking movement on said fulcrum, a sublever actuated by said key-lever, and a type-bar operatively connected to said sublever.

31. In a type-writing machine, the combination of a series of type-bars and a series of key-operated bell-cranks connected thereto and having fulcrum-arms; the fulcrum-arms of said bell-cranks having elongated treads; and a fulcrum-plate whereon said treads have a rocker motion.

32. In a type-writing machine, the combination of a series of type-bars and a series of key-bearing bell-cranks connected thereto and having fulcrum-arms; the fulcrum-arms of said bell-cranks having elongated treads; and a fulcrum-plate whereon said treads have a rocker motion.

33. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars; a series of bell-cranks comprising forwardly-extending key-bearing arms and angular arms, the latter being connected to said type-bars; the points of connection of said angular arms to said type-bars moving forwardly and rearwardly, and said bell-cranks having elongated treads; and a fulcrum-plate along which said treads have a rocker motion.

34. The combination with a type-bar of a three-arm lever, one arm of said lever bearing a key, another arm thereof being connected to said type-bar, and a third arm thereof having an elongated tread; and a bearing member along which said tread has a rocker motion and a change of fulcrum during the rocking motion.

35. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars, a series of key-bearing levers extending forwardly beneath the type-bars, upwardly-extending arms on said key-levers, downwardly-extending arms also on said key-levers, connections between one set of said arms and said type-bars, elongated treads on the other set of said arms, and a support along which said treads have a rocker motion.

36. In a type-writing machine, the combination of a series of type-bars and a series of key-operated bell-cranks connected thereto; the fulcrum-arms of said bell-cranks having elongated treads; a fulcrum-plate whereon said treads have a rocker motion; and means for preventing said treads from becoming displaced longitudinally.

37. In a type-writing machine, the combination of a series of type-bars; a series of key-bearing bell-cranks connected thereto; the fulcrum-arms of said bell-cranks having elongated treads, a fulcrum-plate whereon said treads have a rocker motion, said fulcrum-plate being arranged on edge, and means for preventing longitudinal displacement of said treads.

38. In a front-strike writing-machine, the combination of a series of rearwardly-striking type-bars; a series of T-shaped levers comprising forwardly-extending key-bearing arms, upwardly-extending arms connected to said type-bars, and downwardly-extending-arms having elongated treads; means for preventing vertical displacement of said downwardly-extending arms; and a fixed fulcrum-plate upon which the latter arms have a rocker motion.

39. The combination with a type-bar, of a T-shaped key-lever; connections between said type-bar and one arm of said key-lever, said connections comprising a link, a key carried by another arm of said lever, and a bearing for the third arm of said lever which affords a change of fulcrum during the depression of the key-lever.

810,361. HYDROMETER TEST-JAR. FRANCIS STORR, Maywood N. J. Filed Apr. 24, 1905. Serial No. 257,205.

Claim.—1. A device of the character described, comprising integral communicating tubes, and a supporting lug or extension integral with the lower inner wall of one of said tubes.

2. A device of the character described, comprising a primary tube, an auxiliary tube parallel and integral with said primary tube, said auxiliary tube of less diameter than said primary tube, and a supporting lug or extension formed integral upon the lower inner wall of said auxiliary tube.

3. A device of the character described, comprising a primary, transparent tube, an auxiliary, transparent tube parallel and integral with said primary tube, said auxiliary tube being provided with a constricted portion, and an inwardly-extending lug or extension formed upon said constricted portion.

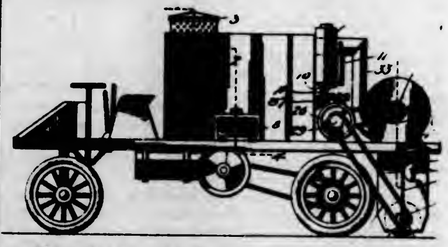
4. A device of the character described, comprising integral, parallel tubes, one of said tubes being provided with a constricted portion, and an inwardly-projecting lug or extension formed upon the inner wall of said constricted portion.

5. A device of the character described, comprising a primary tube, an auxiliary tube parallel and integrally connected at its bottom to the lower portion of said primary tube, said auxiliary tube of less diameter than said primary tube, said auxiliary tube being provided with a constricted portion near its lower end, and an inwardly-extending lug or extension formed upon the inner wall of said constricted portion of the auxiliary tube.

6. A device of the character described, comprising integral tubes, a constricted portion formed upon one of said tubes, and article-supporting means formed upon the inner wall of the constricted portion of said tube.

7. A hydrometer test-jar comprising two hollow receptacles in direct communication with each other, one of said tubes being smaller than the other, the larger of said tubes arranged to receive a hydrometer, and the smaller of said tubes arranged to loosely receive a thermometer, the lower portion of said tube being constricted and having inwardly-extending lugs made integral with the tube, said lugs arranged to support the thermometer in said tube.

810,362. STREET-CLEANING APPARATUS. NAPOLEON ST. PETER, Jr., Fairfield, Me., assignor of two-thirds to David King, Fairfield, Me., and Joseph Carlveau, Waterville, Me. Filed Mar. 2, 1904. Serial No. 196,186.



Claim.—In a street-cleaning device, a supporting-frame, a hood depending from the frame and formed with vertical slots and extending at one side beyond the frame, a brush-shaft vertically movable in said slots and having brushes, a second shaft extending through the upper portion of said hood and having segments, chains secured to said segments and connected with said brush-shaft, and a handle-lever fixed to one of the segments for operating the shaft, substantially as specified.

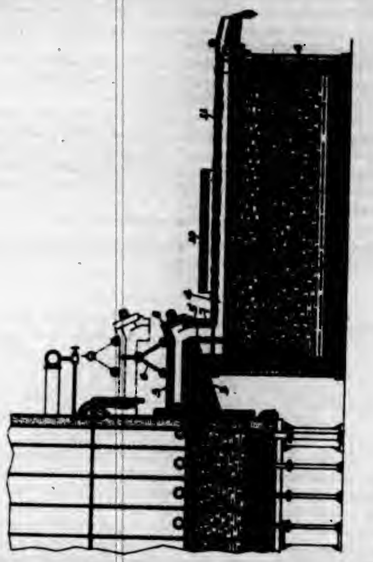
810,363. MATCH. ADOLF SWOBODA, Vienna, Austria-Hungary, assignor of one-half to Walter Bekmayer, Modling, near Vienna, Austria-Hungary. Filed July 12, 1905. Serial No. 269,422.

Claim.—1. The composition of matter consisting of powdered cork, iron minium, flour and water substantially as described and for the purpose specified.

2. The herein-described composition of matter as additional matter to igniting compounds for matches of all kinds consisting of three parts of weight of powdered cork, fifteen parts of weight of iron minium, twenty-three parts of weight of flour and forty parts of weight of water, substantially as described.

3. The herein-described composition of matter consisting of powdered cork, iron minium, flour and water in combination with an igniting compound for matches consisting of: fifty-seven parts of weight of chlorate of potassium, seven parts of weight of red chromate of potassium, seven parts of weight of amorphous phosphorus, fifteen parts of weight of powdered glass, thirty parts of weight of gum-arabic and forty parts of weight of water, substantially as described.

810,364. METHOD OF SAVING METAL VALUES FROM SLAG. CHARLES M. ALLEN, Lolo, Mont. Filed Sept. 1, 1904. Serial No. 223,994.



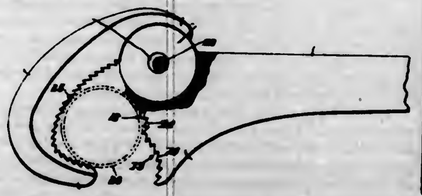
Claim.—1. The method of saving metal values from slags, which consists in withdrawing the slag and matte from beneath the surface of the molten bath, thereby trapping the blast, and permitting them to overflow from a furnace-spout into a forehearth or separating-chamber, and conserving the original heat of the matte and slag by protecting them from the chilling effect of air during their flow into the forehearth or separating-chamber; substantially as described.

2. The method of saving metal values from slags, which consists in withdrawing the slag and matte from beneath the surface of the molten bath, thereby trapping the blast, and permitting them to overflow from a furnace-spout into a forehearth or separating-chamber, and conserving the original heat of the matte and slag by covering them throughout their entire transit into the forehearth; substantially as described.

3. The method of saving metal values from slags, which consists in withdrawing the slag and matte from beneath the surface of the molten bath, thereby trapping the blast, and permitting them to overflow from a furnace-spout into a forehearth or separating-chamber, and conserving the original heat of the matte and slag by covering them with heat-radiating surfaces throughout their entire transit into the forehearth; substantially as described.

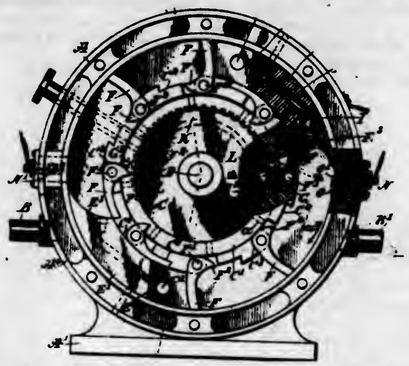
4. The method of saving metal values from slags, which consists in withdrawing the slag and matte from beneath the surface of the molten bath, thereby trapping the blast, and permitting them to overflow from a furnace-spout into a forehearth or separating-chamber, and conserving the original heat of the matte and slag by covering them with a practically air-tight conduit which extends around the course of the falling stream of slag, and into the slag-covering of the forehearth; substantially as described.

810,365. PIPE-WRENCH. HERBERT C. BARLOW, Goldendale, Wash. Filed June 29, 1905. Serial No. 267,482.



Claim.—In a wrench, a stock having a stationary jaw at one end with two or more concaved surfaces having transverse spaced teeth, and with semicircular spaced ears having a transverse pin disposed at one side of the center thereof, a movable jaw member having a hook at one end and with spaced transverse teeth in its inner face and a semicircular member bearing between said ears and with a transverse aperture for receiving said pin and larger than the same, said movable jaw having lateral shoulders bearing constantly upon said spaced ears at the side opposite from said terminal hook.

810,366. ROTARY EXPLOSION-ENGINE. PETER BARTOLETTI, Brownsville, Pa. Filed Feb. 3, 1905. Serial No. 243,998.



Claim.—1. A rotary explosion-engine comprising a cylinder, a piston mounted to turn concentrically therein, an abutment in the cylinder, between the peripheral face of the piston and the inner face of the cylinder, piston-heads fulcrumed on the said piston and adapted to fold into recesses in the said peripheral face of the piston, means for opening the piston-heads after passing the abutment, an air admission in the abutment, opening into the cylinder at the forward end of the abutment, and a gas-supply chest held in the cylinder, within the rim of the said piston, somewhat in advance of the said abutment, the said piston having ports adapted to register with the said chest.

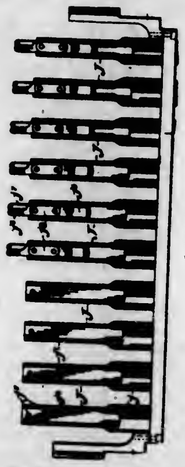
2. A rotary explosion-engine comprising a cylinder, a piston mounted to turn concentrically therein, an abutment in the cylinder, between the peripheral face of the piston and the inner face of the cylinder, piston-heads fulcrumed on the said piston and adapted to fold into recesses in the said peripheral face of the piston, means for opening the piston-heads after passing the abutment, an air admission in the abutment, opening into the cylinder at the forward end of the abutment, and a gas-supply chest held in the cylinder, within the rim of the said piston, somewhat in advance of the said abutment, the said piston having ports adapted to register with the said chest, the ports being located in the rear of the pivotal ends of the piston-heads.

3. A rotary explosion-engine comprising a cylinder, a piston mounted to turn concentrically therein, an abutment in the cylinder, between the peripheral face of the piston and the inner face of the cylinder, piston-heads fulcrumed on the said piston and adapted to fold into recesses in the said peripheral face of the piston, means for opening the piston-heads after passing the abutment, an air admission in the abutment, opening into the cylinder at the forward end of the abutment, a gas-supply chest held in the cylinder, within the rim of the said piston, somewhat in advance of the said abutment, the said piston having ports adapted to register with the said chest, and an electric igniting device extending into the cylinder, in advance of the said abutment, the said igniting device having contacts adapted to be closed by the said piston-heads.

4. A rotary explosion-engine comprising a cylinder, a piston mounted to turn concentrically therein, an abutment in the cylinder, between the peripheral face of the piston and the inner face of the cylinder, piston-heads fulcrumed on the said piston and adapted to fold into recesses in the said peripheral face of the piston, means for opening the piston-heads after passing the abutment, an air admission in the abutment, opening into the cylinder at the forward end of the abutment, a gas-supply chest held in the cylinder, within the rim of the said piston, somewhat in advance of the said abutment, the said piston having ports adapted to register with the said chest, and check-valves for the said air admission and the said gas-supply chest.

8. A rotary explosion-engine comprising a cylinder provided with a plurality of spaced abutments, a piston mounted to turn continuously in the said cylinder and provided with piston-heads fluted on the rim of the piston and adapted to fold into recesses in the rim on coming in contact with the abutments, means for opening the piston-heads on leaving the abutments, an igniting device in front of each abutment, an exhaust in the rear of each abutment, a valved air admission in each abutment, and a gas-supply chest in the cylinder, provided with spaced connected chambers arranged in advance of the abutments, the said piston having ports in the rear of the piston-heads and adapted to register with the said chambers.

810,867. LAMP-JACK FOR TELEPHONE-SWITCHBOARDS. SIDNEY A. REYLAND, Elyria, Ohio, assignor to The Dean Electric Company, Elyria, Ohio, a Corporation of Ohio. Filed Nov. 26, 1904. Serial No. 234,302.



Claim.—1. A lamp-jack for telephone-switchboards formed of one piece of metal, having its front end inclosed in tubular form for a sufficient space to inclose the bulb of an incandescent lamp, and having its rear end extended and formed into a straight-sided channel, with contact-springs and interposed insulation fitted to and rigidly held within said channel, substantially as described.

2. A lamp-jack for telephone-switchboards formed from a single piece of metal comprising a tubular inclosing front portion, and an extended rear portion formed into a straight-sided channel, said tube and channel being lined with insulating material, substantially as described.

3. A lamp-jack strip for telephone-switchboards comprising a front bar or support of metal having a series of openings distributed along its length, transverse terminal securing members for said bar, and a series of metal jack-tubes having their front ends secured in the openings in the bar and their rear ends extended to receive and support contact-springs, substantially as described.

4. A lamp-jack strip for telephone-switchboards comprising a front bar or support of metal having a series of openings distributed along its length, transverse terminal securing members for said bar, and a series of metal jack-tubes having the front ends secured in the openings in the bar and their rear ends extended to receive and support contact-springs, together with insulating-linings for said tubes extending between the jack-contacts and the sides of the tube, and between the lamp-contacts and the same when a lamp is inserted, substantially as described.

5. A lamp-strip for telephone-switchboards comprising a metal front bar or support, metal jack-frames supported thereon by their front ends, contact-springs supported upon said frames, and a lamp in each jack having its terminals in contact with said springs, the front end of each jack-frame being formed as a tube of sufficient length to inclose the bulb of the lamp and so prevent cross-illumination, substantially as described.

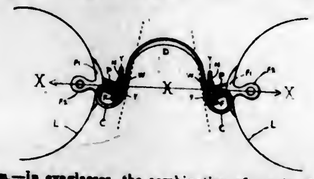
6. In a telephone-switchboard, a tubular lamp-jack and a holding plate or strip therefor, an insulating-lining for said jack, and a circuit-finder comprising a holder frictionally supported on the jack, and a translucent or transparent body carried by said holder, substantially as described.

7. In a telephone-switchboard, a lamp-jack composed of a metal tube adapted to receive and inclose the bulb of an incandescent lamp, and having one side extended and carrying contact-springs for the lamp, substantially as described.

8. In a jack-strip for switchboards, an escutcheon-plate covering the openings of one or more jacks and pivoted to be turned so as to expose the same, substantially as described.

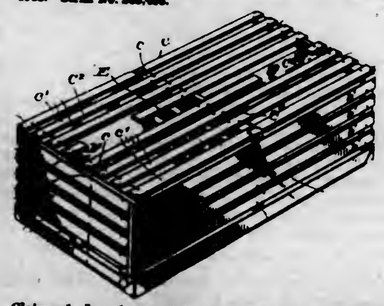
9. In a lamp-jack strip for telephone-switchboards, a front strip having jack-openings therein, an escutcheon-plate pivoted between and with its ends covering two of said openings in normal position, but adapted to be turned to expose the openings, and translucent windows or number-plates in said escutcheon, substantially as described.

810,868. EYEGLASSES. WALTER B. CAWOOD, Toledo, Ohio. Filed Jan. 30, 1905. Serial No. 243,285.



Claim.—In eyeglasses, the combination of a pair of lenses, a pair of lens-holders comprising flanges F′ and F², lens-posts inclined downwardly from flanges F′, side flanges F united at right angle to the inclined lens-posts, a nose-guard and a flexible metallic bridge-spring united intermediate of the post-flanges the bridge-spring comprising sectional portions consisting of an arch or dome D having extended portions or plates W said plates located beyond the post-flanges and parallel thereto, vertical convoluted portions C forming a direct continuation of plates W said convolutions looped in the vertical plane whereby the glasses may be spread apart longitudinally when applied to the nose of the wearer, the aforesaid bridge-spring united to the post-flanges by a yoke-plate and neck said yoke-plate seated intermediate of the post-flanges in the vertical plane the neck portion extending over the top of the post-flanges thence downward parallel with the flange and cojoining the aforesaid vertical convolution of the bridge-spring, the said metallic convolution adapted to enter the intermediate channel of the nose-guard substantially as and for the purpose specified.

810,869. KNOCKDOWN CRATE. JAMES M. DIVAN, Freeport, Ill., assignor of one-half to William Bolton, Montrose, Mo. Filed June 2, 1905. Serial No. 263,492.



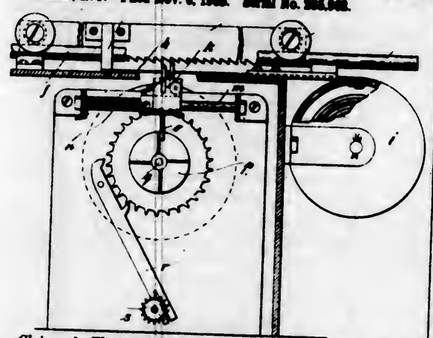
Claim.—1. In a device of the class described, the combination with a suitable bottom, foldable sides and top sections, of foldable end sections hinged to the ends of the bottom and arranged to swing down upon the same, and a central partition having a movable pivot connection with the bottom, whereby it can be erected at the center of the bottom, or folded down at the center of the same.

2. In a device of the class described, the combination with a suitable bottom, foldable sides and top sections, of foldable end sections hinged to the ends of the bottom and arranged to swing down upon the same, a central partition, projecting pins at the lower corners thereof, plates having slots supported by the bottom with which the pins engage, said slots extending substantially from the center of the bottom toward one end thereof, a distance equal to substantially half the height of the partition, whereby the partition can be erected at the center of the bottom, with the pins at one end of the slot, or folded down on the center of the bottom with the pins at the other ends of the slots.

3. In a device of the class described, the combination with a bottom, ends hinged at the ends thereof, sides hinged at the edges thereof and top sections hinged to the sides, of hooks at the free corners of the top sections, and corresponding hooks arranged in pairs at the centers of the tops of the ends, said hooks being constructed and arranged to engage mutually to hold the crate in its erected position.

4. In a device of the class described, the combination with a bottom, sides hinged thereto, top sections hinged to the side sections, and ends hinged to the ends of the bottom, of a partition pivoted to the bottom and arranged to swing down at the center thereof, an upward projection on said partition and a rotatable button on said projection arranged to engage with the adjacent edges of the top sections to look the crate in a closed position.

810,870. TIME-RECORDING APPARATUS. WILBUR I. POLLETT, Summit, N. J. Filed Nov. 6, 1905. Serial No. 285,962.



Claim.—1. Workman's time-recording apparatus comprising a card-holder and time-printing mechanism one bodily movable relatively to the other in the direction only of the maximum dimension of the card-holder, and a time-controlled motor progressively actuating such movable member automatically from one extreme position to the other extreme position correspondingly with the lapse of time to progressively bring to the impression-point consecutive portions of the printing-surface of a card representing a work period of a day.

2. Workman's time-recording apparatus comprising the combination of an impression device and a card-holder bodily movable relatively thereto in the direction only of the maximum dimension of the card-holder, and a time-controlled motor progressively actuating the card-holder automatically from one extreme position to the other extreme position correspondingly with the lapse of time to progressively bring to the impression-point consecutive portions of the printing-surface of a card representing a work period of a day.

3. Workman's time-recording apparatus comprising the combination of impression devices and a card-holder, one of said members being movable bodily relatively to the other in one straight line only from one extreme position to the other extreme position, and a time-controlled motor automatically actuating such movable member step by step corresponding with equal subdivisions of an hour to consecutively bring to the impression-point successive equally-spaced portions of the printing-surface of a card representing a work period of a day.

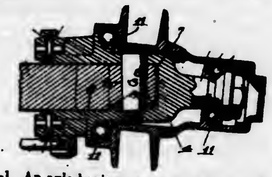
4. Workman's time-recording apparatus comprising the combination of impression devices and a card-holder, one of said members being bodily movable relatively to the other in the direction of the maximum dimension of the card-holder from one extreme position to the other extreme position, and time-controlled means automatically actuating said member step by step corresponding with equal subdivisions of an hour to consecutively bring to the impression-point successively equally-spaced portions of the printing-surface of a card representing a work period of a day.

810,871. ABSORBENT BANDAGE. WILLARD R. GREEN, Muscatine, Iowa. Filed Dec. 22, 1905. Serial No. 293,193.

Claim.—1. An absorbent material for surgical purposes, comprising a mass of grass of strand or ribbon like form treated to render the same curly, and mingled together, and a supporting member therefor.

2. An absorbent material for surgical purposes, comprising a mass of heat-treated curly grass intermingled with fiber, such for instance as a wood or vegetable fiber, and supporting means therefor.

810,872. STEERING-KNUCKLE FOR VEHICLES. JACKSON O. HAAS, Pottsville, Pa. Original application filed Oct. 21, 1904, Serial No. 229,461. Divided and this application filed Feb. 16, 1905. Serial No. 245,996.



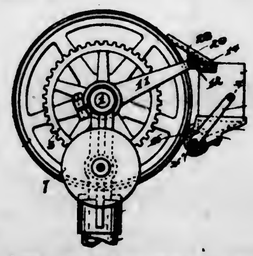
Claim.—1. An axle having an approximately cylindrical head, a steering-knuckle having a recess pivotally engaging said head, the lower wall of said recess constituting a flange concentric with the pivot, and a hook-shaped member upon the axle engaging said flange.

2. An axle having a forwardly-curved terminal end and provided with an approximately cylindrical head, in combination with a steering-knuckle having a recess receiving and pivotally engaging said head.

3. The combination with an axle terminating in an approximately cylindrical head, of a steering-knuckle pivotally engaging said head and provided with bosses upon its under side, and a bell-crank lever constituting a steering-arm and having apertures registering with said bosses and suitably connected therewith.

4. The combination with an axle having lateral extensions constituting a curved track and provided with an approximately cylindrical head, and a steering-knuckle having a flaring recess engaging said head pivotally and concentric with the curved track; the upper and lower walls of said recess constituting housings; and members mounted for rotation in said housings and engaging the curved track.

810,873. CEMENTING-MACHINE. WILLIAM F. LAUTENSCHLAGER, Cincinnati, Ohio, assignor of one-half to the Krippendorf-Dittmann Company, Cincinnati, Ohio, a Corporation. Filed Apr. 26, 1905. Serial No. 257,496.



Claim.—1. A cementing-machine comprising a frame, a hollow spreading-roll journaled thereon, a driving-shaft journaled on said frame and extending into said hollow roll, means for rotating said roll, a cement-reservoir pivotally supported on said frame, having a distributing portion bearing against the surface of the roll, and a hollow cylindrical valve seated within said reservoir, and means for rotating said valve to adjust the delivery of cement, substantially as described.

2. A cementing-machine comprising a frame, a cement-supplying roll journaled upon said frame, driving mechanism comprising a

stud-shaft, provided with a fixed pulley and pinion supported at opposite ends, a shaft to which said cement-roll is fixed and journaled, a gear mounted on said shaft and fixed to said cement-roll and receiving motion from said pinion, said gear and pinion being mounted within the rim of the cement-roll, a cement-reservoir pivotally supported on said frame and detachable therefrom, its distributing portion being held by gravity against the surface of the roll, a valve seated within said reservoir, and a wiper detachably supported on the frame, having a bearing upon the periphery of the roll and projecting into the reservoir, substantially as described.

3. A cementing-machine comprising a frame, a cement-supplying roll journaled upon said frame, being provided with a glazed surface, means for driving said roll, a cement-reservoir detachably supported on said frame, provided with a roll-bearing surface held by gravity against the roll, a valve seated within said reservoir at each roll-bearing portion of the reservoir, and adapted to form a seal therewith and with the parts so arranged that the valve-opening is greater than the thickness of the cement applied to the surface of the roll, a wiper detachably supported on the frame, having a bearing upon the periphery of the roll and projecting into the reservoir, substantially as described.

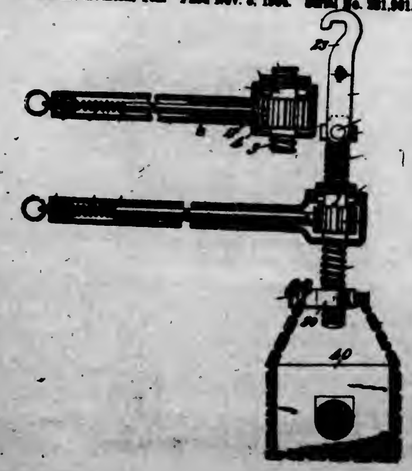
4. A cementing-machine comprising a frame, a cement-supplying roll journaled upon said frame, means for driving said roll, a cement-reservoir detachably supported on said frame, and provided with a roll-bearing surface held by gravity against the roll, a valve seated within said reservoir at each roll-bearing portion of the reservoir, and adapted to form a seal therewith and with the parts so arranged that the valve-opening is greater than the thickness of the cement applied to the surface of the roll, a wiper detachably supported on the frame, having a bearing upon the periphery of the roll and projecting into the reservoir, substantially as described.

5. A cementing-machine comprising a frame, a cement-supplying roll journaled upon said frame, means for driving said roll, a cement-reservoir detachably supported on said frame, provided with a roll-bearing surface held by gravity against said roll, said bearing surface being provided with surplus cement receiving and distributing channels leading to the mouth of the valve, a valve seated within said reservoir at each roll-bearing portion of the reservoir, and adapted to form a seal therewith and with the parts so arranged that the valve-opening is greater than the thickness of the cement applied to the surface of the roll, and a wiper detachably supported on the frame, having a bearing upon the periphery of the roll and projecting into the reservoir, substantially as described.

6. In a cementing-machine, a cementing-roll provided with a glazed surface, a reservoir having an outlet-valve engaging against the roll and adapted to supply a coating of cement, and a wiper engaging said roll, substantially as described.

7. In a cementing-machine, a cementing-roll having a glazed surface, a reservoir provided with a cylindrical valve-outlet bearing against said roll, means for regulating said valve, and a wiper engaging said roll, substantially as described.

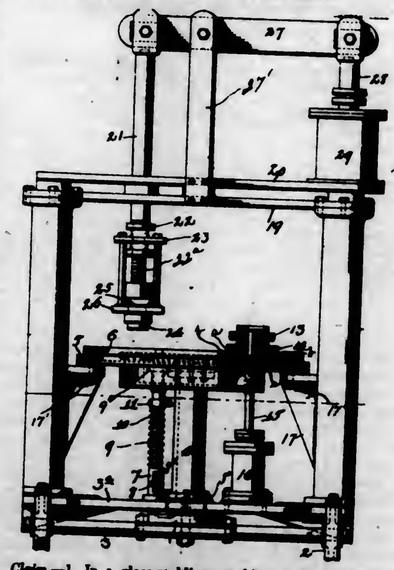
810,374. DOUBLE-SCREW SWIVEL LIFTING-JACK. WILLIAM C. MOSSER, Houston, Tex. Filed Nov. 8, 1904. Serial No. 231,961.



Claim.—1. In a lifting-jack, and in combination, a rod or shaft having a ratchet-wheel rigidly attached at its center, and having screw-threads of opposite pitch toward its ends, a hollow handle consisting of a box portion inclosing said ratchet-wheel and pawl and a handle portion, and a rod extending to the end of the handle, by which said pawl may be operated, and a nut at each end of the shaft, having threads corresponding with the threads of the shaft, each nut having means for attachment to external bodies.

2. In a lifting-jack, the combination of a screw-shaft having a fixed ratchet on its central portion and screw-threads of opposite pitch in the direction of its ends, a hollow handle having a box portion surrounding said ratchet, said box having a threaded cover and surrounding the ratchet-wheel, a spring-pressed pawl in the hollow handle and box and extending to the end of said handle, said pawl engaging said ratchet-wheel, and nuts with threads of opposite pitch at the opposite ends of said screw-shaft, each nut provided with means for attachment to an outside body.

810,375. GLASS-MANUFACTURING APPARATUS. MCCLELLAND MYERS, Mexico, Pa., assignor of one-half to John P. Hitchs, Indiana, Pa. Filed Feb. 17, 1904. Serial No. 193,976.



Claim.—1. In a glass-molding machine, a base, a stationary table having an aperture supported above the base, a table rotatably mounted on the stationary table, a sleeve on the base, said sleeve being provided with a slot, a latch having one end passing through the aperture of the stationary table, and normally engaging the rotatable table to hold the same against movement, the opposite end of the latch fitting within the sleeve, a collar on the latch, and a spring embracing the latch and contacting with the collar and sleeve to hold the latch in its normal position, and a treadle secured to the latch and extending through the slot of the sleeve.

2. In a glass-molding machine, a suitable truck, a table mounted and rotatable thereon, molds carried by the table, a presser-head, a rod for the presser-head, a nut threaded on the rod of the presser-head, a yoke connecting the presser-head to the nut on the rod thereof.

3. In a glass-molding machine, a suitable truck, a table mounted and rotatable thereon, molds carried by the table, means for arresting the table holding it at predetermined intervals, a presser-head operated thereabove in conjunction with the molds, a rod for the presser-head having a threaded lower end, a nut run on the threads thereof, a yoke connected to the nut, and to the presser-head.

4. In a glass-molding machine, a suitable truck, a table mounted and rotatable thereon, molds carried by the table, means for arresting the table holding it at predetermined intervals, a presser-head operated thereabove in conjunction with the molds, a rod for the presser-head having threaded lower ends, a nut run on the threads thereof, a yoke connected to the nut end to the presser-head, a lever suitably pivoted and connected to the upper end of the rod of the presser-head and means for oscillating the lever.

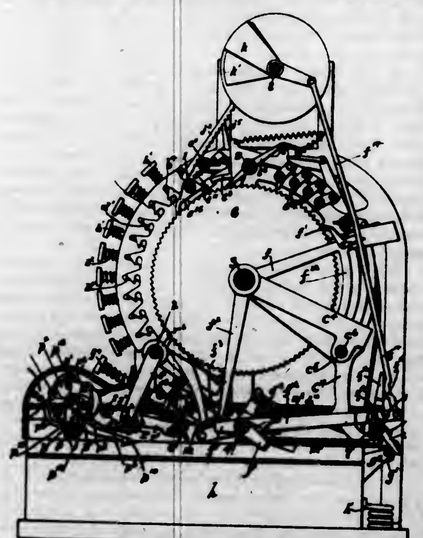
5. In a glass-molding machine, a suitable truck, a table mounted and rotatable thereon, the said table having a series of apertures and spring-pressed detent adapted to enter the apertures and arrest the table, molds carried by the table, a presser-head operating from above in conjunction with the mold, the said table being held by the detent with the molds successively under the said presser-head, an ejector carried by each mold and a piston-rod operated to lift the ejectors as they are successively brought into alinement with the said piston-rod.

6. In a glass-molding machine, a suitable truck, a table mounted and rotatable thereon, the said table having a series of apertures and spring-pressed detent adapted to enter the apertures and arrest the table, molds carried by the table, a presser-head operating from above in conjunction with the mold, the said table being held by the detent with the molds successively under the said presser-head, an ejector carried by each mold and a piston-rod operated to lift the ejectors as they are successively brought into alinement with the said piston-rod, a suitable rod for carrying the presser-head, a lever for operating the presser-head, a piston-rod for reciprocating the lever and a suitable cylinder and piston in conjunction with which the piston-rod operates.

7. In a glass-molding machine, a rotatably-mounted table, molds carried by the table, ejectors carried by the molds, and a piston-rod for operating the ejectors and means for holding the molds in alinement with the piston-rod.

8. In a glass-molding machine, a stationary table provided with an aperture, a table rotatably mounted thereon, molds carried by the rotatable table, ejectors for the molds adjusted to aline with the aperture of the stationary table, and a piston-rod passing through the aperture to engage the ejector for operating the same.

810,376. CASH INDICATOR AND RECORDER. JOHN H. MCCORMICK and JAMES D. MORRISON, Columbus, Ohio, assignors, by mesne assignments, to The International Register Company, Columbus, Ohio, a Corporation of Ohio. Filed Apr. 5, 1905. Serial No. 254,553.



Claim.—1. In a cash-register, a keyboard having a series of keys arranged in groups, a series of registering-wheels also arranged in groups, each group comprising a wheel of different denomination corresponding to each group of keys, intermediate actuating devices common to all the registering-wheels and one for each denomination, each key of a series being adapted to unlock and determine the movement of the actuating device corresponding to said series, a movable part, such as a cash-drawer, adapted when released to operate said actuating devices, a pawl-lever for each registering-wheel, all the pawl-levers of one group being normally locked, and department-keys, each adapted to release the pawl-levers of one group and also the movable part, a series of printing-wheels also arranged in groups, one printing-wheel for each registering-wheel, said wheels being adapted to print on a common record-strip, and means as described for causing the printing-wheel of each registering-wheel actuated to contact with said recording-strip, substantially as specified.

2. In a cash-register, a keyboard, and a series of registering devices, each comprising a group of registering-wheels, intermediate actuating devices common to all the registering-levers, each of the keys in one group or series being adapted to unlock and determine the movement of one of said actuating devices, means whereby the registering-wheels of any series or group may be released so as to be actuated by the actuating devices, and printing-wheels also arranged in groups, one printing-wheel for each registering-wheel, and a recording-strip common to all the printing-wheels, and means as described for causing the printing-wheels corresponding to the registering-wheels operated to be brought in contact with the recording-strip so as to record the number registered on said wheels and each of them, substantially as specified.

3. The combination with a keyboard having keys arranged in groups or series, one group or series for each denomination, a series of printing-wheels also arranged in groups, each group comprising a wheel for each denomination represented on the keyboard, intermediate actuating devices, each of the keys of any series being adapted to unlock and determine the movement of the actuating device of said series, a lever connected to each of said printing-wheels and adapted when released to move with the actuating device of the denomination corresponding to said wheel, department-keys for releasing the levers of any group, a recording-strip common to all the printing-wheels, and means as described for bringing said recording-strip in contact with the wheels whose levers have been released when the actuating devices are operated, substantially as specified.

4. The combination with a keyboard, and keys arranged in groups representing different denominations, intermediate actuating devices, one for each group or series of keys, each key of said group or series being adapted to unlock and determine the position of its actuating device, a series of printing-wheels, one for each denomination represented by said keys, means as described for operating each of said printing-wheels by the movement of the actuating devices of the same denomination, and a recording-strip adjacent to said printing-wheels, and a moving part, such as a cash-drawer, adapted, by its opening and closing, to operate said actuating devices, and a connection from said moving part to the recording-strip whereby said strip is moved into contact with the printing-wheels operated by the actuating devices and advanced after said contact, substantially as specified.

5. In a cash-register, a keyboard having keys arranged in groups, intermediate actuating devices, one for each group, each key of each group being adapted to release and determine the movement of its actuating device, a movable part, such as a cash-drawer, adapted to operate all of said actuating devices when released, a series of printing-wheels also arranged in groups, each group constituting a department, each of which has a wheel corresponding to each series of keys, connections from each of said wheels to the actuating devices of corresponding denomination, a recording-strip mounted on movable rollers common to all the printing-wheels, releasing-keys for each department, and means as described for causing the recording-strip to contact with the printing-wheels of that department which has been released after the same have been moved by the actuating devices, substantially as specified.

6. In a cash-register, a series of registering devices each comprising registering-wheels of different denominations, a series of printing-wheels, one for each registering-wheel, means for normally locking each registering device including the printing-wheels, intermediate actuating devices, one corresponding to each denomination represented in the respective registering devices, and a keyboard having keys arranged in series, one series for each actuating device, said actuating device being common to all the registering devices, each key of each series being adapted to release and determine the movement of the actuating device of that series, a recording-strip common to all the registering devices, means for unlocking either of the registering devices to cause its registering and printing wheels to be simultaneously actuated by the actuating devices, a recording-strip common to all the printing-wheels and adapted to contact with those printing-wheels which have been released, and a type-bar adapted to contact with said recording-strip when some of said registering devices are released, and means for

withdrawing said type-bar from contact with said recording-strip when any registering device is actuated, substantially as specified.

7. In a cash-register, a series of cash-keys, and a series of normally inactive registering devices, a series of printing devices, one for each registering device, and special keys for said registering devices and said printing devices, said special keys being adapted when operated to put said registering and printing devices both into operative condition to register and record the amount indicated on said cash-keys, substantially as specified.

8. A series of cash-keys and a series of department-registering devices, a printing device for each registering device, intermediate actuating devices common to all the registering devices and printing devices, and special keys for simultaneously throwing into operative condition the registering and printing devices of each department, substantially as specified.

9. A series of department-registering devices and means for operating the same, a series of printing devices, one for each department and adapted to be operated simultaneously with the registering devices of said departments, and means for holding said registering and printing devices normally in an inoperative position, and special keys adapted to simultaneously release said printing and registering devices to cause them to act in unison from their common actuating devices, substantially as specified.

10. A series of department registering devices, and a series of printing devices, one for each depariment and adapted to print on a common recording-strip the amounts added on the respective registering devices, and means common to both series for operating the same.

11. A series of registering devices arranged in groups, and actuating-bars extending across all of said registering devices, movable keys for determining the movement of said actuating-bars, each of said bars representing a different denomination and having in each registering device a wheel corresponding thereto, engaging devices for said wheels actuated by said bars, printing-wheels, and connections from each of said engaging devices to a printing-wheel, a lock common to all the engaging devices of one group, and a special key for releasing said lock, and a connection from said key to its corresponding printing-wheels to cause the printing-wheels to be brought into operative position when the engaging devices are released, substantially as specified.

12. A series of cash-keys, and a series of printing-wheels, said printing-wheels being arranged in groups corresponding to departments, and intermediate actuating devices controlled by said cash-keys and adapted to operate said printing-wheels, said printing-wheels being adapted to print on a common record-strip, and special keys to throw said printing-wheels in an operative position to cause them to act on said common printing-strip, substantially as specified.

13. A series of cash-keys, and a series of printing-wheels arranged in groups, intermediate actuating devices to operate said printing-wheels, said actuating devices being controlled by the cash-keys, means for holding said printing-wheels in a normally inactive position, and special keys, one for each group, to bring said printing-wheels into an operative position, and interlocking devices connected with said special keys to lock all the other printing devices when one of said special keys is operated, substantially as specified.

14. A series of printing-wheels, cash-keys adapted through intermediate actuating devices to determine the movement of said printing-wheels, and special keys for bringing said printing devices into operative position, a cash-drawer adapted by its movement to operate said printing-wheels and a change-key adapted to unlock said drawer and at the same time lock all of said printing-wheels, a printing device connected to said change-key adapted to be brought into contact with a record-strip common to all of said printing devices when the drawer is opened by said change-key, substantially as specified.

15. A cash-register having registering devices, and printing-wheels arranged in groups, and adapted to print on a common record-strip, a series of cash-keys to control the actuating devices for said printing-wheels, means common to said registering devices and the printing-wheels to actuate the same simultaneously, means for feeding said printing-strip after the printing-wheels are operated against the same, said printing-strip being wider than the total width of said printing-wheels to form a blank space opposite the impression from either of said printing-wheels, substantially as specified.

16. The combination with a series of cash-keys and a series of printing-wheels arranged in groups, actuating devices controlled by said cash-keys and adapted to operate said printing-wheels, of a roller-frame containing a series of rollers extending across the printing-wheels of all the groups, and supporting a record-strip extending across said printing-wheels, and an inking-roller common to all of said printing-wheels and adjacent said frame, substantially as specified.

17. The combination with a series of cash-keys, of a series of printing-wheels arranged in groups, actuating devices controlled by said cash-keys and adapted to operate said printing-wheels, a pivoted frame having rollers carrying a printing-strip, an inclosing casing having an opening, one of said rollers being an impression-roller and arranged normally opposite said opening in the inclosing casing, special keys for bringing all the printing-wheels of one set or group into operative position, and means as described for oscillating said pivoted frame to carry the impression-roller opposite said printing-wheel and causing a contact between said impression-roller and printing-wheel, substantially as specified.

18. The combination with the printing-wheels and means for revolving the same, a pivoted frame having rollers supporting a record-strip, swinging arms for supporting said pivoted frame, means as described for revolving said frame to bring one of said rollers opposite said printing-wheels and for causing a movement of said frame toward said wheels by oscillating the swinging arms, substantially as specified.

19. The combination with the printing-wheels of a pivoted frame supported in swinging arms, supporting-rollers in said frame, and an impression-roller between said supporting-rollers, a printing-strip connected at each end to said supporting-rollers and passing over said impression-roller, means as described for turning said frame to bring said impression-roller opposite said printing-wheels and for moving said swinging arms to cause the strip to contact with said printing-wheels, substantially as specified.

20. The combination with the printing-wheels, rollers supporting a record-strip and an impression-roller over which said strip passes, a pivoted frame in which said rollers are journaled, swinging arms supporting said frame, means for turning said frame and oscillating said arms, and a ratchet device operated by the movement of said frame to partially revolve said rollers as said frame is moved, substantially as specified.

21. In a machine for registering and indicating the amounts of certain classes of transactions, such as cash sales, and for printing and indicating the amount of transactions of other classes, the combination of the registering mechanism, the indicating mechanism, and means for throwing or maintaining the registering mechanism out of operation when it is desired to print and indicate the amount of a transaction which is not to be registered upon the registering mechanism.

22. In a machine for registering the amounts of transactions of a given class, such as cash sales, and for recording and indicating the amounts of such transactions and also the amounts of other special classes of transactions, the combination with the operating mechanism or actuating devices of the machine, of a register positively actuated thereby to register the amounts of all cash transactions, printing and indicating devices also actuated thereby to print and indicate the amounts of all transactions of all classes, and means for rendering the registering mechanism inoperative at will whenever a transaction is to be recorded and indicated but not added upon the registering mechanism.

23. In a machine for registering the amounts of transactions of a given class, such as cash sales, and for recording and indicating the amounts of such transactions and also the amounts of other special classes of transactions, the combination, with the operating mechanism or actuating devices of the machine, of a register actuated thereby to register the amounts of all cash transactions, printing and indicating devices also actuated thereby to print and indicate the amount of all transactions of all classes, special indicating devices for indicating the character of the various transactions, and means for maintaining the registering mechanism out of operation at will when a transaction is to be recorded and indicated but not added upon the registering mechanism.

24. In a machine for registering the amounts of certain classes of transactions, such as cash sales, and for recording the amounts of transactions of other classes, the combination, with the operating mechanism, of a register adapted to be operated thereby for registering the amounts of cash transactions, printing means for printing the amounts of special transactions, value-keys for controlling the operation of the registering and printing mechanisms, a special key, means for preventing the operation of the operating mechanism until the special key is depressed, and means for maintaining the register out of operation when the special key is depressed.

25. In a machine for registering the amounts of certain classes of transactions, such as cash sales, and for recording the amounts of transactions of other classes, the combination with the operating mechanism, of a register adapted to be operated thereby for registering the amounts of cash transactions, printing means adapted to record the amounts of transactions not to be added on said register, value-keys for controlling the operation of the register and the printing means, a plurality of special keys representing different characters of transactions, means for preventing the operation of the operating devices until one of said special keys is depressed, and means for maintaining the register out of operation when any one of the said keys that does not represent cash transactions is depressed and the machine is then operated.

26. In a machine for registering and indicating the amounts of certain classes of transactions, such as cash sales, and for recording and indicating the amounts of transactions of other classes, the combination with the operating mechanism, of a register adapted to be operated thereby for registering the amounts of cash transactions, indicating devices for indicating the amounts of all transactions, printing means adapted to record the amounts of transactions not to be added upon the register, value-keys for controlling the operation of the register, the indicating devices and the printing means, a plurality of special keys representing different characters of transactions, means for preventing the operation of the operating devices until one of the special keys is depressed, and means for maintaining the register out of operation when any one of the said keys that does not represent cash transactions is depressed and the machine is then operated.

27. In a machine for registering and indicating the amounts of certain classes of transactions, such as cash sales and for recording and indicating the amounts of transactions of other classes, the combination, with the operating mechanism, of a register adapted to be operated thereby for registering the amounts of cash transactions, indicating devices adapted to be operated thereby for indicating all transactions, printing means adapted to record the amounts of transactions not to be added on the register, value-keys for controlling the operation of the register, the indicating devices and the printing means, a plurality of special keys representing different characters of transactions, means for indicating the character of the transaction made, means for preventing the operation of the operating devices until one of the said special keys is depressed, and means for maintaining the register out of operation when any one of the said keys that does not represent cash transactions is depressed and the machine is then operated.

28. In a registering-machine having operating mechanism, a register that is adapted to be operated by said mechanism, an indicating and a printing device, said devices being operated by said mechanism to indicate and record both the value and the character of every transaction, and means for rendering the register inoperative when a transaction is to be indicated and recorded that is not to be added on the register.

29. In a machine for indicating and recording the values and the character of transactions of various kinds, an operating mechanism that is normally held against movement, a special key representing "cash" transactions, a register that is adapted to be operated when the said special key is depressed and the operating mechanism released, a second special key representing transactions other than "cash" sales, means whereby the said register is thrown or maintained out of operative condition when the said second special key is depressed, means controlled by the latter key for releasing the operating mechanism, and a recording device for taking a permanent record of all transactions of all kinds.

30. In a cash-register, a plurality of registers, an operating mechanism therefor, means whereby any one of said registers may be caused to be operated by said mechanism, a bank of keys adapted to control any register and a recording device adapted to produce a record showing which of the said registers has been operated.

31. In a cash-register, a plurality of registers, an operating mechanism therefor, means whereby any one of said registers may be caused to be operated to the exclusion of all the other registers, a bank of keys adapted to control any register and a recording device adapted to produce a record showing which of the said registers has been operated.

32. In a cash-register, a printing device, a value-key and a department-key, and means requiring the operation of both of said keys before said printing device can be operated.

33. In a cash-register, a registering device, a printer, operating mechanism therefor, a series of keys for determining the movements of said registering and printing mechanism, means for rendering the said registering device inoperative with relation to the said mechanism, a special key for controlling said means, and interlocking mechanism to prevent the simultaneous depression of the cash and special keys.

34. In a cash-register, a registering device, operating mechanism therefor, a series of value-keys for determining the movements of said mechanism, means for throwing or maintaining the said registering device out of operative relation with the said mechanism a special key for controlling said means, interlocking mechanism to prevent the simultaneous depression of the value and the special keys, and a recording device operated by said mechanism and adapted to show that the special key has been depressed.

35. In a cash-register, a transverse shaft, register-operating mechanisms mounted on said shaft, keys for determining the extent of movement of said operating mechanisms, means for normally locking said mechanisms against operation, a plurality of special keys, means operated by either of said special keys for unlocking said mechanisms, a recording device and means controlled by said special keys for causing said recording device to show the character of the transaction.

36. In a cash-register, a series of special keys, an operating mechanism, means actuated by said keys for releasing said mechanism, a recording device adapted to show which of said keys has been used to release the mechanism, and means to prevent the simultaneous operation of two or more of said keys.

37. In a cash-register, a registering device, an operating mechanism therefor, a depressible key, means whereby the register is actuated after said key is depressed and when the said mechanism is operated, a second depressible key, means for throwing or maintaining said registering device out of operation when said second key is depressed, and a recording device adapted to show which of the said keys has been depressed.

38. In a cash-register, a plurality of registering devices, an operating mechanism therefor, means whereby any one of said registering devices may be placed in operative relation with said mechanism, an indicating device for showing at each operation of the machine which register is operating, and a recording device for keeping a continuous record of the various indications.

39. In a cash-register, a series of registering devices, an operating mechanism for said devices, means for placing any one of the said devices into operative relation with the operating mechanism at will, means to prevent the simultaneous operation of a second registering device, and a recording mechanism for showing which register has been operated.

40. In a cash-register, a transverse shaft, register-operating mechanisms mounted on said shaft, keys for determining the extent of movement of said operating mechanisms, means for normally locking said mechanisms against operation, a plurality of special keys, means operated by said keys for unlocking said mechanisms, and a recording device adapted to show which of said special keys has been operated.

41. In a cash-register, a registering device, means for maintaining the same out of operation, and a printing device adapted to produce a record showing that the register has not been operated.

42. In a cash-register, adapted to the use of a plurality of clerks or departments, a plurality of devices for separating the transactions of each clerk or department, and an additional means for recording and identifying the transactions in each of said departments.

43. In a cash register and indicator adapted to the use of a plurality of clerks or different characters of transactions, a plurality of devices for showing the variable amount or values of the total transactions of each clerk or each character of transactions, an additional means from which the same information can be obtained, said additional means affording a basis of comparison of the information furnished by the first means.

44. In a cash-register adapted to the use of a plurality of clerks or departments, a plurality of devices from which the total amount of the transactions by each clerk or department can be obtained, and a printing device for recording and identifying the transactions of each clerk or department, said printing device furnishing means for comparison with the total transactions in each of the first-mentioned devices.

45. In a cash-register adapted to the use of a plurality of clerks or departments, a plurality of devices for separating the transactions of each clerk or department, and showing the total thereof, a printing device for recording and identifying each transaction of each of the clerks or departments, whereby the same information as to the transactions in different departments may be obtained from different sources.

46. In a cash-register, a series of pairs of normally inoperative registers and recorders, means for operating the same, and means for rendering each of said pairs operative or inoperative as desired.

47. In a cash-register, a series of registers, separate means for

operating cash register, means for normally locking each of said operating means, a series of keys, one key for each register, by the depression of which the corresponding operating means is unlocked, and a printing device adapted to produce a record showing which of the operating means has been unlocked.

48. In a registering-machine, a series of registers, separate devices for operating the registers, a series of sets of recorders set from said operating devices, means for normally locking each of said devices, and means for unlocking any register and recorder desired.

49. In a cash-register, a bank of cash or value keys, a series of normally inoperative registers, a swinging frame controlled by said bank of keys, means for operating said registers from said frame, means for rendering operative any desired register, and means controlled by said frame for recording the amount added upon the register.

50. In a cash-register, a series of printing devices normally held out of printing position, means for setting any desired printer for printing the transaction and for throwing said printer into printing position, a platen carrying a strip of paper, and means for moving said platen and paper into contact with said printer.

51. In a cash-register, a plurality of department registering devices, means for operating the same, a plurality of printing devices, one for each department, and mechanism common to both series for setting the register-operating means and the printing devices simultaneously.

52. In a cash-register, a printing device, a value-key, and means for locking said printing device out of operative position upon the depression of said key.

53. In a cash-register, a recording device which is normally out of operative position, a value-key, a department-key, and means requiring the operation of both of said keys for placing said recording device in its operative position.

54. In a cash-register, a recording device that is normally out of inoperative position, a rock-shaft, and means on said shaft for throwing the recording device into operative position and for locking it into such position.

55. In a registering-machine, a plurality of sets of registering-wheels, a series of printing devices, and connections between said sets of registering-wheels and their corresponding printing devices such that each amount added on a register-wheel will be printed by the corresponding printing device.

56. In a cash-register, a series of sets of recorders, separate means for operating each of said sets of recorders, mechanism for normally locking each of said sets of recorders, and means for unlocking and rendering operative any recorder desired.

57. In a cash-register, the combination with a registering device, of a main yoke, a series of auxiliary yokes operated by the same, graduated step-segments connected to said yokes, keys for limiting the movements of said segments, a printer including type-carriers, and means connecting the type-carriers to the respective segments.

58. In a cash-register, the combination with a registering device, of a main yoke, a series of auxiliary yokes operated by the same, graduated step-segments connected with said auxiliary yokes, keys for controlling the movements of said segments, and type-carriers connected with the auxiliary yokes.

59. In a cash-register, the combination with a registering device, of a main yoke, a series of auxiliary yokes operated by the same, graduated step-segments connected with said auxiliary yokes, means for limiting the movements of the segments, and a printer including type-carriers, said type-carriers being moved proportionately with the segments.

60. In a cash-register, a main yoke, a series of auxiliary yokes operated thereby, graduated step-segments connected with the auxiliary yokes, means for limiting the movements of the segments, and a registering device, said device being operated proportionately with the segments.

61. In a cash-register, the combination with registering devices, of a main operating-yoke, a series of auxiliary yokes, devices for controlling the movements of these latter yokes, a printing device including type-carriers and means connecting the type-carriers to the respective auxiliary yokes.

62. In a cash-register, a registering device, a special key, means for maintaining the register out of operation when the key is actuated, a special indicator under the control of the special key, a bar for turning the indicator, said bar having a shoulder, a plate for engaging said shoulder and holding the indicator in set position between operations of the machine, and a recording device adapted to produce a record showing that the register has not been operated.

63. In a cash-register, a registering device, a special key, means for maintaining the register out of operation when the key is actuated, a special indicator under control of the special key, means for holding the indicator in its set position between successive operations of the machine and a recording device adapted to produce a record showing that the register has not been operated.

64. In a paper-feeding device for cash-registers, a supply-roller, a take-up roller, and a feed-roller, movable bearings for said take-up roller, and a spring for the latter roller which presses the same between the supply and the feed rollers.

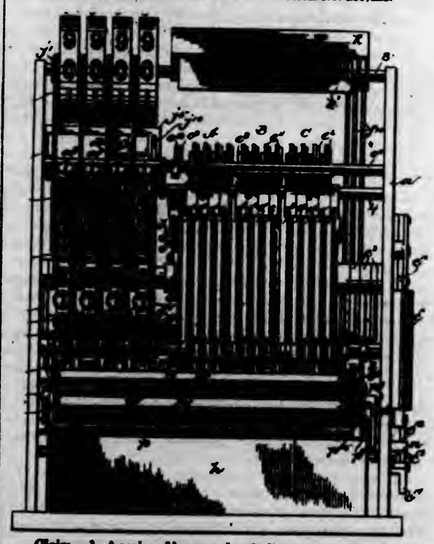
65. In a cash-register, two separate recorders, a value-key, and means for placing one recorder in operative condition and locking the other recorder out of operative condition upon the depression of said key.

66. In a cash-register, the combination with a main yoke, of a series of auxiliary yokes operated thereby, means for limiting the movements of the auxiliary yokes, a series of type-carriers, means for maintaining an unbroken connection between the auxiliary yokes and type-carriers, a series of indicators, and means for connecting the indicators to the auxiliary yokes while the latter are moving in one direction only.

67. In a cash-register, the combination with a main yoke, of a series of auxiliary yokes operated thereby, means for limiting the movements of the auxiliary yokes, a series of type-carriers, means for maintaining an unbroken connection between the type-carriers and the auxiliary yokes, a platen, and means for returning the auxiliary yokes arranged to first operate the platen.

810,877. CASH REGISTER AND INDICATOR. JOHN H. McCONNICK, Columbus, Ohio, and JAMES D. MORRISON, Washington, D.C.

Original application filed Apr. 5, 1895, Serial No. 544,863. Divided and this application filed Nov. 20, 1905. Serial No. 288,686.



Claim.—1. A series of keys, and an indicator having numbers corresponding to each key, a rack-bar adapted to operate said indicator, and a pivoted lever attached to said rack-bar, an intermediate pivoted actuating device having on opposite sides of its pivotal center projections to engage said pivoted lever, one of said projections being stationary and the other movable, a movable part, such as a cash-drawer, for returning said actuating device to its normal position, and a connection from said movable part to the movable projection on said actuating device whereby said movable projection may be disengaged from said pivoted lever to permit the actuating device to return to its normal position while the indicator remains, substantially as specified.

2. The combination with a series of keys, and an intermediate actuating device, an indicating-wheel, a pivoted lever connected to said wheel so as to move therewith, said pivoted lever being normally connected to said actuating device on opposite sides of the pivotal center, and means as described for disengaging said pivoted lever on one side of its pivotal center when the actuating device is returned to its normal position, and a catch for retaining said indicator in the position to which it is moved by said actuating device, substantially as specified.

3. A series of keys, an intermediate actuating device, and a movable part, such as a cash-drawer, adapted by its movement to operate said actuating device, means for unlocking and determining the movement of said actuating device when a key is depressed, an indicating-wheel having a series of numbers corresponding to the number of keys, and a pivoted lever connected to said wheel, a connection from said actuating device to said pivoted lever on opposite sides of its pivotal center, a catch for retaining said indicating-wheel in the position to which it is moved by said actuating device, and means as described for disengaging the pivoted lever from said actuating devices on one side of the pivotal center when said actuating device is returned to its normal position, substantially as specified.

4. A series of keys arranged in groups, an intermediate actuating device for each group, and a registering-wheel for each actuating device, a pawl-lever having a pawl to engage with each of said registering-wheels and adapted to move with said actuating device, means connected with each of said keys for unlocking and determining the movement of the actuating device belonging to its series or group, and a movable part, such as a cash-drawer, to cause said actuating device to move to a predetermined distance and return to its normal position, transferring-pawls adjacent to each of said registering-wheels except the lowest in denomination, and means for engaging said transferring-pawls with said registering-wheel by a predetermined movement of the registering-wheel of the next lowest denomination and a spring-actuated lever adapted to be released when said actuating mechanism is returned to its normal position and to successively actuate said pawl-levers so as to move their respective registering-wheels a limited distance, substantially as specified.

5. In a cash-register, a series of registering-wheels, each representing a different denomination, means for independently actuating each of said registering-wheels to register units corresponding to the denomination of said wheel, pawl-levers for each of said registering-wheels except the lowest in denomination, said pawl-levers being adapted to be operated by a predetermined movement of the wheel of the next lower denomination to cause the pawl to engage with its registering-wheel, a series of rock-shafts each having a projecting finger and each connected to one of said pawl-levers, a spring-actuated lever adapted when released to contact with all of the fingers on said rock-shafts, and means for releasing said spring-actuated lever when the registering-wheel of any denomination has completed its movement, substantially as specified.

6. In a cash-register, registering devices and cash-keys, for determining the movement thereof, a cash-drawer connected to said registering devices so as to actuate the same by the movement of said cash-drawer, and a governor connected to said drawer and to said registering devices, said governor being adapted to insure a uniform speed of the same during its entire return movement and further adapted to regulate the speed of the registering devices, substantially as specified.

7. A cash-register having a normally closed cash-drawer and a connection from said drawer to the registering devices, a pivoted bar connected to said registering devices, and a speed-regulator connected to said bar, for causing the speed of said drawer to be uniform during its entire movement, and means on said bar to prevent the closing of said drawer after the operation of opening the same is begun, substantially as specified.

8. In a registering-machine, a plurality of indicators, a movable frame for each indicator, connections between each indicator and its frame for moving the indicator by the frame, and means for locking and unlocking said connections and frame.

9. In a registering-machine, a plurality of indicators, a movable member for each indicator, connections between each indicator and its member, means for locking each of said connections to its respective member when said members are moving in one direction, and means for unlocking said connections and members when the latter are moving in the opposite direction.

10. In a registering-machine, an indicator, a pivoted frame, connections between said indicator and frame, a pivoted latch on said frame for engaging and locking said connections to the frame while it is moving in one direction, and means for shifting said latch to unlock said connections from the frame so that the latch may move independently in the opposite direction.

11. In a registering-machine, a drawer, an indicator, a pivoted frame, a connection between said indicator and frame, a pivoted latch on said frame for engaging and locking said connection to the frame while it is moving in one direction, and means operated from the drawer for shifting said latch to unlock said connection from the frame so that the latter may move independently in the opposite direction.

12. In a cash-register, the combination with a register, of operating-levers for the same, an indicating device, an operating-lever for said indicating device, a movable locking device mounted on said former lever to lock into the last-mentioned lever, and a tripping means for actuating said locking device.

13. In a cash-register of the class described the combination with a registering mechanism, of pivoted operating devices for the same, an indicating device, operating-levers for said indicating device, and means for positively connecting the operating-levers and the pivoted operating devices whereby they are locked together upon the downward movement but released upon the upward movement.

14. In a cash-register, a registering device, a special key, means for maintaining the register out of operation when the key is actuated, a special indicator under the control of the special key, a bar for turning the indicator, said bar having a shoulder, and a plate for engaging said shoulder and holding the indicator in set position between operations of the machine.

15. In a cash-register, a drawer, an indicator, a pivoted frame, connections between said indicator and frame, a pivoted latch on said frame for engaging and locking said connections to the frame while it is moving in one direction and means operated from the drawer for shifting said latch to unlock said connections from the frame so that the latter may move independently in the opposite direction.

16. In a cash-register, an indicator, a pivoted frame, connections between said indicator and frame, a pivoted latch on said frame for engaging and locking said connections to the frame while it is moving in one direction, and means for shifting said latch to unlock said connections from the frame, so that the latter may move independently in the opposite direction.

17. In a cash-register, a series of registering-wheels, operating mechanism therefor, a transfer-pawl for each of said wheels except the one of lowest denomination, a rock-shaft for each of said pawls, said shafts being arranged successively one in advance of the other, and means for rocking said shafts to effect the transfer immediately after the movement of the operating mechanism has been substantially completed.

18. In a registering mechanism, a series of registering-wheels, operating mechanism therefor, transfer-lugs on said wheels, pawl-carriers mounted coaxially with the wheels, pawls on said carriers, means for normally holding said pawls out of engagement with their corresponding wheels, means controlled by said lugs for causing the pawls to drop into engagement with their wheels, and means for successively moving said pawl-carriers so that those pawls which have been dropped will move their wheels to effect a transfer, said movement of the wheels taking place immediately after the movement of the operating mechanism has been substantially completed.

19. In a cash-register, a series of registering-wheels, operating mechanism therefor, a pawl for each of said wheels except the one of lowest denomination, means for normally holding said pawls out of operative position, lugs on said wheels for causing said pawls to drop into operative position, means for moving said pawls, and a rock-shaft provided with means for lifting said pawls back out of operative position, said movement and lifting of the pawls taking place immediately after the movement of the operating mechanism has been substantially completed.

20. In a cash-register, a series of registering-wheels, operating mechanism therefor, lugs on said wheels, pawl-carriers pivoted coaxially with said wheels, pawls on said carriers, means for holding said pawls out of operative position, means controlled by said lugs for dropping the pawls into operative position, rock-shafts connected with said pawl-carriers, means for successively rocking said rock-shafts to move said pawl-carriers, and another rock-shaft provided with means for restoring said pawls to their original positions, said rock-shafts being moved after the movement of the operating mechanism has been substantially completed.

21. In a cash-register, a series of registering-wheels, operating mechanism therefor, transfer-lugs on said wheels, transfer-pawls, means for normally holding said pawls out of engagement with their respective wheels, means operated by said lugs for causing said pawls to drop into engagement with their wheels, a rock-shaft for each pawl, and means for rocking said shafts to move the pawls and to cause those pawls that are dropped to move their respective wheels, said movement of the wheels taking place immediately after the movement of the operating mechanism has been substantially completed.

22. In a cash-register, a series of registering-wheels, an operating mechanism therefor, a series of transfer-pawls for said wheels, a series of rock-shafts for moving said pawls, another rock-shaft for disconnecting said pawls from said wheels, and a common means for successively rocking all of said shafts, said movement of the shafts taking place after the movement of the operating mechanism has been substantially completed.

23. In a cash-register, an indicator, a rack-bar for rotating said indicator, means for moving said rack-bar, a latch for holding said rack-bar and indicator from overthrowing a cash-drawer, means controlled by said drawer for disengaging the latch, and a rock-shaft for tripping said means and permitting the same to again engage and hold the rack.

24. In a cash-register, an indicator, means for operating said indicator, a latch engaging said means and holding the indicator from overthrowing, means for withdrawing the latch and releasing the indicator, and means for tripping the latch so that it may again engage the operating means.

25. In a cash-register, the combination with an operating mechanism, of a series of amount-keys, a series of special keys normally inoperative in connection with the operating mechanism, a change or "No-sale" key normally operative and means operated by the amount-keys for rendering the special keys operative and the "No-sale" key inoperative.

26. In a cash-register, the combination with an operating mechanism, of a series of amount-keys, a cash-drawer, a drawer-latch, a series of special keys normally inoperative in connection with said latch, a change or "No-sale" key normally operative in connection with said latch, and means operated by the amount-keys for rendering the special keys operative and the "No-sale" key inoperative in connection with the latch.

27. In a cash-register, the combination with an operating mechanism, of a series of amount-keys, a cash-drawer, a special key controlling said drawer, and means operated by the amount-keys for rendering the special key inoperative, in relation to the drawer.

28. In a cash-register, the combination with an operating mechanism, of a series of amount-keys, a cash-drawer, a change or "No-sale" key for opening said drawer, a special indicator for said key, and means operated by the amount-keys for rendering the change or "No-sale" key inoperative in connection with the cash-drawer and indicator.

29. In a cash-register, the combination with an operating mechanism, means for normally holding said mechanism against operation, a key for releasing said mechanism, and a printing device set by the operation of the release-key.

30. In a cash-register, the combination with an operating mechanism, a cash-drawer by means of which said mechanism is operated, a "No-sale" key for opening said drawer and a printing device controlled by said "No-sale" key.

31. In a cash-register, in combination with an operating mechanism, of a series of amount-keys, a series of special keys, normally inoperative in connection with the operating mechanism, a change or "No-sale" key normally operative, means operated by the amount-keys for rendering the special keys operative and the "No-sale" key inoperative, and a printing device controlled by the "No-sale" key.

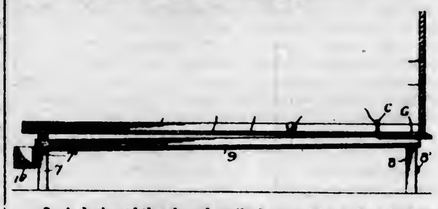
32. In a cash-register, the combination with an operating mechanism, of a series of amount-keys, a cash-drawer, a drawer-latch, a series of special keys normally inoperative in connection with said latch, a change or "No-sale" key normally operative in connection with said latch, means operated by the amount-key for rendering the special keys operative and the "No-sale" key inoperative in connection with the latch, and a printing device under control of the "No-sale" key.

33. In a cash-register, the combination with an operating mechanism, of a series of amount-keys, a cash-drawer, a special key controlling said drawer, means operated by the amount-keys for rendering the special key inoperative in relation to the drawer, and a printing device controlled by said special key.

34. In a cash-register, the combination with an operating mechanism, of a series of amount-keys, a cash-drawer, a change or "No-sale" key for opening said drawer, a special indicator for said key, means operated by the amount-keys for rendering the change or "No-sale" key inoperative in connection with the cash-drawer and indicator, and a printing device under control of the "No-sale" key.

810,378. [illegible] Queen S. Ferris, Rockford, Ill. Original application filed [illegible]. Divided and this application filed Oct. 19, 1903. Serial No. 177,855.

Claim.—4. A device of the class described, comprising a board adapted for the passage of projectiles thereover and having an opening at one end for the passage of said projectiles therethrough, legs hinged to the board and foldable to lie against the under surface thereof, a runway pivotally connected with certain of said legs and a supporting-brace connected with others of said legs and arranged to receive and support the runway, said runway being disposed to receive the projectile from the opening and being arranged to lie between the legs when the latter are in their folded positions.

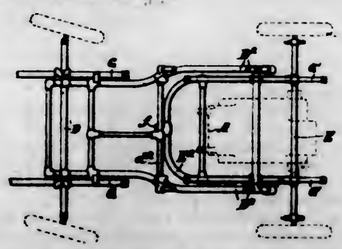


2. A device of the class described comprising a board adapted for the passage of projectiles thereover, pairs of legs hinged to the board adjacent to the opposite ends thereof, said legs being foldable to lie against the under surface of the board, a runway pivoted adjacent to one of its ends between one pair of the legs, and being disposed to receive projectiles from the board, said runway extending normally between the legs of the other pair, a brace carried by the last-named pairs of legs and arranged to receive the runway thereupon when the latter is in its normal position, said brace being located in a plane below the pivot-point of the runway, said runway being arranged to lie between the legs of both pairs and against the under surface of the board, when the legs are in their folded positions, and means co-operating with the runway and with one of the pairs of legs for holding the runway and the legs in their operative positions.

3. In a table of the class described, the combination with a board, of legs hinged to the board and foldable to lie against the under surface thereof, a runway pivoted to certain of said legs at one end and lying when in its normal position with its other end between others of said legs, said runway being arranged to receive projectiles from the board and being arranged to lie against the under surface of the board when the legs are in their folded positions, a support for the free end of the runway and means for holding the runway against movement with respect to the legs to hold the legs and the runway in their operative positions.

4. In a table of the class described, the combination with a board, of pairs of spaced legs hinged to the board at opposite ends thereof, said legs being foldable to lie against the under surface of the board, a runway pivoted at one end between one pair of said legs, and lying normally with its free end between the other pair, a brace carried by the last-named pair of legs and disposed to receive and support the free end of the runway, said runway being arranged to lie between the legs of both pairs and against the under surface of the board when the legs are in their folded positions, said brace being arranged to lie against the under face of the runway, when the latter and the legs are in their folded positions, means for holding the runway and the legs in operative position, and means for holding them in their folded positions.

810,379. MOTOR-VEHICLE. HARRY M. PEVE, Chicopee Falls, Mass., assignor, by mesne assignments, to Morton Trust Company, trustee, a Corporation of New York. Original application filed Oct. 23, 1899. Serial No. 734,689. Divided and this application filed Sept. 10, 1903. Serial No. 172,863.



Claim.—1. In a motor-vehicle, the combination with a motor, driving-connections, driving-wheels and independent steering-wheels, of a two-part running-gear frame, one part of said frame supporting an axle which is held from movement in a horizontal plane and which is provided with independent steering-wheels, the second part supporting the motor, driving connections and the driven wheels in fixed relation therewith, said second part being suspended at one point from the first-named part whereby the wheels may accommodate themselves to an uneven surface without distortion of the motor and driving connections, and a spring connection between the two reach members.

2. In a motor-vehicle, the combination with a motor, driving connections, driving-wheels and independent steering-wheels, of a two-part running-gear frame, each part of which frame includes an axle member, said parts being connected to each other at a single point whereby the wheels may accommodate themselves to an uneven surface, and spring connections between the two reach members and between one of said reach members and the axle to which it is secured.

3. In a motor-vehicle, the combination with a motor, driving connections, driving-wheels and independent steering-wheels, of a two-part running-gear frame, each part of which frame includes an axle member and a frame-like reach member extending therefrom and toward the opposite axle, and a universal connection between the sections of the running-gear frame and intermediate the axles.

4. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and independent steering-wheels, a running-gear frame comprising a pair of axles and two frame-like reach members extending therefrom, a universal connection between the two reach-members intermediate the axles, and a spring connection between the two reach members.

5. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and independent steering-wheels, a running-gear frame comprising a pair of axles and two reach members extending from said axles toward each other, one of said reach members being spring-supported upon one axle, and a universal connection between the two reach members intermediate the axles.

6. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and independent steering-wheels, a running-gear frame comprising a pair of axles, two reach members, a universal connection between the axles, and spring connections between said reach members adjacent to one of the axles.

7. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and independent steering-wheels, a running-gear frame comprising a pair of axles, two reach members, a universal connection between said members and intermediate the axles, spring connections between said reach members intermediate the universal joint and one of the axle members.

8. In combination in a motor-vehicle including a motor, driving-wheels, driving connections, a non-pivotal axle, and independent steering-wheels pivoted upon said axle, a running-gear frame comprising two members supported upon said wheels respectively, one of said members carrying the motor and being pivotally mounted on the other member, said other member having intermediate spring connections with the non-pivotal axle.

9. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising a main member supporting a body or seats, springs at the rear end of said frame and a second member carrying the motor and driving mechanism having pivotal connections at its front end with the main member and directly connected to the rear axle without the interposition of springs.

10. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and individually-pivoted steering-wheels, a running-gear frame comprising a motor-carrying frame and a second frame having a cross-bar on which the motor-carrying frame is pivoted, and spring connections intermediate the second frame and the axles, whereby the axles are held substantially in parallelism.

11. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising a motor-carrying frame and a second frame having longitudinal side bars between and on which the motor-carrying frame is hung.

12. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising a motor-carrying frame and a second frame having longitudinal side bars and a cross-bar on which the motor-carrying frame is pivoted.

13. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising a motor-carrying frame supported at one end at two points, and a second frame also supported at one end at two points and at the other end upon the first-named frame, said first-named frame being pivotally hung at its other end on the second frame.

14. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising a frame supported at two points and a second frame also supported at two points having a cross-bar on which the first-named frame is pivoted.

15. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising a frame supported at two points and a second frame having longitudinal side bars between and on which the first-named frame is hung.

16. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising a frame supported at two points and a second frame having longitudinal side bars and a cross-bar on which the first-named frame is pivoted.

17. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a main frame adapted to support the body or seats, springs supporting said main frame, a second frame carrying the motor and transmission mechanism being at its forward end pivotally connected with the main frame, and having connections with the rear axle for holding it substantially at right angles therewith.

18. In combination with a motor-vehicle including a motor, a rear axle, driving connections from the motor to the rear axle, a front axle, and individually-pivoted wheels thereon, a running-gear frame comprising a member supported at two points from the rear axle and carrying the motor, and a second member supported at its forward end from the front axle and extending rearwardly with reach portions projecting beside the motor-carrying member, said second member having spring connections in the rear and being adapted to carry the body of the vehicle, and said motor-carrying member extending forwardly from the rear axle between the reach portions of the second member and being supported at its forward end pivotally upon the second member.

19. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising two members, one member carrying the motor and pivotally connected at its front end to the other member, and springs on the forward axle supporting the combined load of the forward ends of the two members, said other member having spring connections intermediate therewith and the rear axle.

810,380. BUNDLE-LOADER. JOHN S. RICHARDSON, Nowata, N. D., assignor to Walter Gregory, trustee, Minneapolis, Minn. Filed Dec. 8, 1903. Renewed Sept. 19, 1904. Serial No. 224,901.

Claim.—1. In a bundle-loader, the combination of an elevator, means for picking bundles up from the ground, and an endless apron arranged to receive from said means and discharge to the elevator, and comprising slats having forward sides disposed at right angles to its stretches, and also having rear sides the outer portions of which are beveled.

2. In a bundle-loader, the combination of an elevator, means for picking bundles up from the ground, an endless apron arranged to receive from said means and discharge to the elevator, a roller intermediate of the apron and the elevator for preventing the return of bundles from the latter to the former, and means for driving the apron and said roller.

3. A bundle-loader having a horizontal, rotary pick-up provided with blades disposed tangentially to its axis.

4. In a bundle-loader, a pick-up comprising a rotary shaft, brackets on said shaft, having arms disposed tangentially with respect to the shaft, and blades carried by said arms of the brackets and arranged parallel to the shaft.

5. In a bundle-loader, the combination of an elevator, a rotary pick-up comprising a shaft, and blades disposed tangentially with respect to the shaft, and an endless apron arranged to receive from the pick-up and discharge to the elevator, and comprising slats having forward sides disposed at right angles to its stretches, and also having rear sides the outer portions of which are beveled.

6. In a bundle-loader, the combination of a main frame, a traveling drive-wheel, an endless elevator, a rotary pick-up disposed at right angles to the elevator, an endless apron arranged to receive from the pick-up and discharge to the elevator, driving connections intermediate of the drive-wheel and the elevator, pick-up and apron,

22. In a cash-register, a series of registering-wheels, an operating mechanism therefor, a series of transfer-pawls for said wheels, a series of rock-shafts for moving said pawls, another rock-shaft for disconnecting said pawls from said wheels, and a common means for successively rocking all of said shafts, said movement of the shafts taking place after the movement of the operating mechanism has been substantially completed.

23. In a cash-register, an indicator, a rack-bar for rotating said indicator, means for moving said rack-bar, a latch for holding said rack-bar and indicator from overthrowing a cash-drawer, means controlled by said drawer for disengaging the latch, and a rock-shaft for tripping said means and permitting the same to again engage and hold the rack.

24. In a cash-register, an indicator, means for operating said indicator, a latch engaging said means and holding the indicator from overthrowing, means for withdrawing the latch and releasing the indicator, and means for tripping the latch so that it may again engage the operating means.

25. In a cash-register, the combination with an operating mechanism, of a series of amount-keys, a series of special keys normally inoperative in connection with the operating mechanism, a change or "No-sale" key normally operative and means operated by the amount-keys for rendering the special keys operative and the "No-sale" key inoperative.

26. In a cash-register, the combination with an operating mechanism, of a series of amount-keys, a cash-drawer, a drawer-latch, a series of special keys normally inoperative in connection with said latch, a change or "No-sale" key normally operative in connection with said latch, and means operated by the amount-keys for rendering the special keys operative and the "No-sale" key inoperative in connection with the latch.

27. In a cash-register, the combination with an operating mechanism, of a series of amount-keys, a cash-drawer, a special key controlling said drawer, and means operated by the amount-keys for rendering the special key inoperative, in relation to the drawer.

28. In a cash-register, the combination with an operating mechanism, of a series of amount-keys, a cash-drawer, a change or "No-sale" key for opening said drawer, a special indicator for said key, and means operated by the amount-keys for rendering the change or "No-sale" key inoperative in connection with the cash-drawer and indicator.

29. In a cash-register, the combination with an operating mechanism, means for normally holding said mechanism against operation, a key for releasing said mechanism, and a printing device set by the operation of the release-key.

30. In a cash-register, the combination with an operating mechanism, a cash-drawer by means of which said mechanism is operated, a "No-sale" key for opening said drawer and a printing device controlled by said "No-sale" key.

31. In a cash-register, in combination with an operating mechanism, of a series of amount-keys, a series of special keys, normally inoperative in connection with the operating mechanism, a change or "No-sale" key normally operative, means operated by the amount-keys for rendering the special keys operative and the "No-sale" key inoperative, and a priating device controlled by the "No-sale" key.

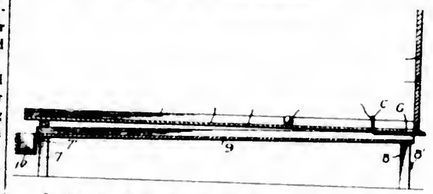
32. In a cash-register, the combination with an operating mechanism, of a series of amount-keys, a cash-drawer, a drawer-latch, a series of special keys normally inoperative in connection with said latch, a change or "No-sale" key normally operative in connection with said latch, means operated by the amount-key for rendering the special keys operative and the "No-sale" key inoperative in connection with the latch, and a printing device under control of the "No-sale" key.

33. In a cash-register, the combination with an operating mechanism, of a series of amount-keys, a cash-drawer, a special key controlling said drawer, means operated by the amount-keys for rendering the special key inoperative in relation to the drawer, and a printing device controlled by said special key.

34. In a cash-register, the combination with an operating mechanism, of a series of amount-keys, a cash-drawer, a change or "No-sale" key for opening said drawer, a special indicator for said key, means operated by the amount-keys for rendering the change or "No-sale" key inoperative in connection with the cash-drawer and indicator, and a printing device under control of the "No-sale" key.

810,378. TABLE. OLIVER B. PEYTON, Rockford, Ills. Original application filed Dec. 9, 1904, Serial No. 236,121. Divided and this application filed Feb. 16, 1905. Serial No. 245,892.

Claim.—1. A device of the class described, comprising a board adapted for the passage of a projectile thereover and having an opening at one end for the passage of said projectiles therethrough, legs hinged to the board and foldable to lie against the under surface thereof, a runway pivotally connected with certain of said legs and a supporting-brace connected with others of said legs and arranged to receive and support the runway, said runway being disposed to receive the projectile from the opening and being arranged to lie between the legs when the latter are in their folded positions.

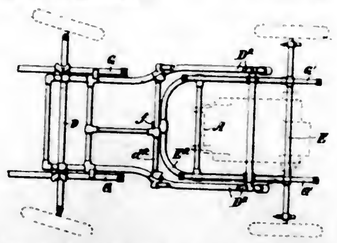


2. A device of the class described comprising a board adapted for the passage of projectiles thereover, pairs of legs hinged to the board adjacent to the opposite ends thereof, said legs being foldable to lie against the under surface of the broad, a runway pivoted adjacent to one of its ends between one pair of the legs, and being disposed to receive projectiles from the board, said runway extending normally between the legs of the other pair, a brace carried by the last-named pairs of legs and arranged to receive the runway thereupon when the latter is in its normal position, said brace being located in a plane below the pivot-point of the runway, said runway being arranged to lie between the legs of both pairs and against the under surface of the board, when the legs are in their folded positions, and means co-operating with the runway and with one of the pairs of legs for holding the runway and the legs in their operative positions.

3. In a table of the class described, the combination with a board, of legs hinged to the board and foldable to lie against the under surface thereof, a runway pivoted to certain of said legs at one end and lying when in its normal position with its other end between others of said legs, said runway being arranged to receive projectiles from the board and being arranged to lie against the under surface of the board when the legs are in their folded positions, a support for the free end of the runway and means for holding the runway against movement with respect to the legs to hold the legs and the runway in their operative positions.

4. In a table of the class described, the combination with a board, of pairs of spaced legs hinged to the board at opposite ends thereof, said legs being foldable to lie against the under surface of the board, a runway pivoted at one end between one pair of said legs, and lying normally with its free end between the other pair, a brace carried by the last-named pair of legs and disposed to receive and support the free end of the runway, said runway being arranged to lie between the legs of both pairs and against the under surface of the board when the legs are in their folded positions, said brace being arranged to lie against the under face of the runway, when the latter and the legs are in their folded positions, means for holding the runway and the legs in operative position, and means for holding them in their folded positions.

810,379. MOTOR-VEHICLE. HARRY M. POPE, Chicopee Falls, Mass., assignor, by mesne assignments, to Morton Trust Company, trustee, a Corporation of New York. Original application filed Oct. 23, 1899. Serial No. 734,490. Divided and this application filed Sept. 10, 1903. Serial No. 172,563.



Claim.—1. In a motor-vehicle, the combination with a motor, driving connections, driving-wheels and independent steering-wheels, of a two-part running-gear frame, one part of said frame supporting an axle which is held from movement in a horizontal plane and which is provided with independent steering-wheels, the second part supporting the motor, driving connections and the driven wheels in fixed relation therewith, said second part being suspended at one point from the first-named part whereby the wheels may accommodate themselves to an uneven surface without distortion of the motor and driving connections, and a spring connection between the two reach members.

2. In a motor-vehicle, the combination with a motor, driving connections, driving-wheels and independent steering-wheels, of a two-part running-gear frame, each part of which frame includes an axle member, said parts being connected to each other at a single point whereby the wheels may accommodate themselves to an uneven surface, and spring connections between the two reach members and between one of said reach members and the axle to which it is secured.

3. In a motor-vehicle, the combination with a motor, driving connections, driving-wheels and independent steering-wheels, of a two-part running-gear frame, each part of which frame includes an axle member and a frame-like reach member extending therefrom and toward the opposite axle, and a universal connection between the sections of the running-gear frame and intermediate the axles.

4. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and independent steering-wheels, a running-gear frame comprising a pair of axles and two frame-like reach members extending therefrom, a universal connection between the two reach-members intermediate the axles, and a spring connection between the two reach members.

5. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and independent steering-wheels, a running-gear frame comprising a pair of axles and two reach members extending from said axles toward each other, one of said reach members being spring-supported upon one axle, and a universal connection between the two reach members intermediate the axles.

6. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and independent steering-wheels, a running-gear frame comprising a pair of axles, two reach members, a universal connection between the axles, and spring connections between said reach members adjacent to one of the axles.

7. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and independent steering-wheels, a running-gear frame comprising a pair of axles, two reach members, a universal connection between said members and intermediate the axles, spring connections between said reach members intermediate the universal joint and one of the axle members.

8. In combination in a motor-vehicle including a motor, driving-wheels, driving connections, a non-pivotal axle, and independent steering-wheels pivoted upon said axle, a running-gear frame comprising two members supported upon said wheels respectively, one of said members carrying the motor and being pivotally mounted on the other member, said other member having intermediate spring connections with the non-pivotal axle.

9. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising a main member supporting a body or seats, springs at the rear end of said frame and a second member carrying the motor and driving mechanism having pivotal connections at its front end with the main member and directly connected to the rear axle without the interposition of springs.

10. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and individually-pivoted steering-wheels, a running-gear frame comprising a motor-carrying frame and a second frame having a cross-bar on which the motor-carrying frame is pivoted, and spring connections intermediate the second frame and the axles, whereby the axles are held substantially in parallelism.

11. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising a motor-carrying frame and a second frame having longitudinal side bars between and on which the motor-carrying frame is hung.

12. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising a motor-carrying frame and a second frame having longitudinal side bars and a cross-bar on which the motor-carrying frame is pivoted.

13. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising a motor-carrying frame supported at one end at two points, and a second frame also supported at one end at two points and at the other end upon the first-named frame, said first-named frame being pivotally hung at its other end on the second frame.

14. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising a frame supported at two points and a second frame also supported at two points having a cross-bar on which the first-named frame is pivoted.

15. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising a frame supported at two points and a second frame having longitudinal side bars between and on which the first-named frame is hung.

16. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising a frame supported at two points and a second frame having longitudinal side bars and a cross-bar on which the first-named frame is pivoted.

17. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a main frame adapted to support the body or seats, springs supporting said main frame, a second frame carrying the motor and transmission mechanism being at its forward end pivotally connected with the main frame, and having connections with the rear axle for holding it substantially at right angles therewith.

18. In combination with a motor-vehicle including a motor, a rear axle, driving connections from the motor to the rear axle, a front axle, and individually-pivoted wheels thereon, a running-gear frame comprising a member supported at two points from the rear axle and carrying the motor, and a second member supported at its forward end from the front axle and extending rearwardly with reach portions projecting beside the motor-carrying member, said second member having spring connections in the rear and being adapted to carry the body of the vehicle, and said motor-carrying member extending forwardly from the rear axle between the reach portions of the second member and being supported at its forward end pivotally upon the second member.

19. In combination in a motor-vehicle including a motor, driving-wheels, driving connections and steering-wheels, a running-gear frame comprising two members, one member carrying the motor and pivotally connected at its front end to the other member, and springs on the forward axle supporting the combined load of the forward ends of the two members, said other member having spring connections intermediate therewith and the rear axle.

810,380. BUNDLE-LOADER. JOHN S. RICHARDSON, Nowesta, N. D., assignor to Walter Gregory, trustee, Minneapolis, Minn. Filed Dec. 8, 1903. Renewed Sept. 19, 1904. Serial No. 224,961.

Claim.—1. In a bundle-loader, the combination of an elevator, means for picking bundles up from the ground, and an endless apron arranged to receive from said means and discharge to the elevator, and comprising slats having forward sides disposed at right angles to its stretches, and also having rear sides the outer portions of which are beveled.

2. In a bundle-loader, the combination of an elevator, means for picking bundles up from the ground, an endless apron arranged to receive from said means and discharge to the elevator, a roller intermediate of the apron and the elevator for preventing the return of bundles from the latter to the former, and means for driving the apron and said roller.

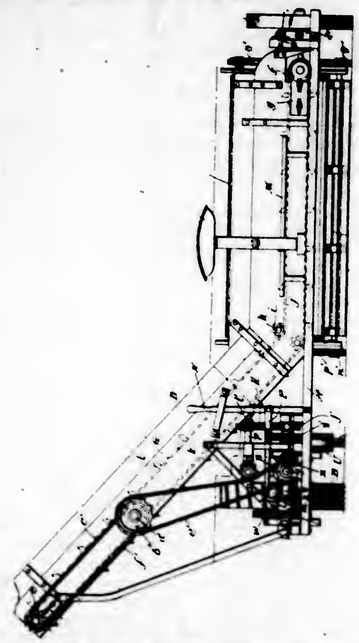
3. A bundle-loader having a horizontal, rotary pick-up provided with blades disposed tangentially to its axis.

4. In a bundle-loader, a pick-up comprising a rotary shaft, brackets on said shaft, having arms disposed tangentially with respect to the shaft, and blades carried by said arms of the brackets and arranged parallel to the shaft.

5. In a bundle-loader, the combination of an elevator, a rotary pick-up comprising a shaft, and blades disposed tangentially with respect to the shaft, and an endless apron arranged to receive from the pick-up and discharge to the elevator, and comprising slats having forward sides disposed at right angles to its stretches, and also having rear sides the outer portions of which are beveled.

6. In a bundle-loader, the combination of a main frame, a traveling drive-wheel, an endless elevator, a rotary pick-up disposed at right angles to the elevator, an endless apron arranged to receive from the pick-up and discharge to the elevator, driving connections intermediate of the drive-wheel and the elevator, pick-up and apron,

and means comprised in said connections for throwing the elevator, pick-up and apron into and out of operation.



7. In a bundle-loader, the combination of a main frame, a traveling drive-wheel carried thereby, an endless elevator, a rotary pick-up disposed at right angles to the elevator, an endless apron arranged to receive from the pick-up and discharge to the elevator, a roller arranged intermediate of the apron and the elevator for preventing the return of bundles from the latter to the former, and driving connections intermediate of the drive-wheel and the elevator, pick-up, apron and roller.

8. In a bundle-loader, the combination of an elevator, a rotary pick-up disposed at an angle to the elevator and comprising a shaft and blades connected with and disposed tangentially to the shaft, an endless apron arranged to receive from the pick-up and discharge to the elevator, and comprising slats having forward sides disposed at right angles to its stretches, and also having rear sides, the outer portions of which are beveled, a roller intermediate of the discharge end of the apron and the elevator for preventing the return of bundles from the latter to the former, and means for driving the elevator, the pick-up, the apron and the roller.

9. The combination in a bundle-loader, of a main frame; a bar pivotally connected to the main frame, and carrying a doubletree or other suitable draft apparatus, a traveling wheel supporting said bar, and carried by a hanger pivotally connected to the bar so as to turn on its axis, a pole connected to said bar, and an adjustable connection between the main frame and the bar.

10. The combination in a bundle-loader, of a main frame, a bar pivotally connected to the main frame, and having an upright provided with a plurality of apertures, a doubletree or similar draft apparatus carried by the bar, a traveling wheel supporting the bar, and carried by a hanger pivoted to the bar so as to turn on its axis, a rod pivoted to the frame, and having an angular portion adapted to engage the apertures of the upright, and a pole pivoted to the bar.

11. In a bundle-loader, the combination with a horisontally-disposed, rotary pick-up adapted to be moved at a slight distance above the ground, and comprising blades disposed tangentially to its axis, and means for rotating said pick-up; of a conveyor arranged to receive bundles from the pick-up.

12. In a bundle-loader, the combination with a main frame suitably supported on carrying-wheels, of an endless elevator and means armed with long blades adapted to be entered under the bundles and to deliver them from the ground to said elevator.

13. In a bundle-loader, the combination with an endless elevator suitably sustained and carried upon a supporting-frame and wheels, of a rotary pick-up device armed with long blades adapted to be entered under the bundles and to deliver the bundles to said elevator.

14. In a bundle-loader, the combination, with a main frame and a traveling drive-wheel, of an endless conveyer carried and operated thereby and arranged to receive the bundles and deliver them upon the wagon, and means armed with long blades for picking up the bundles and depositing them upon the said elevator.

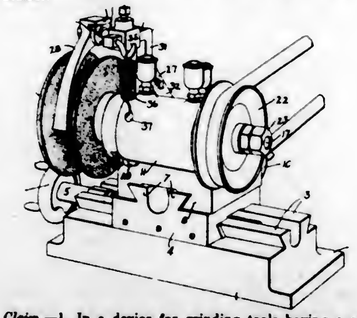
15. In a bundle-loader, the combination with an endless elevator suitably sustained and carried upon a supporting-frame and wheels, of a pick-up mechanism armed with long blades adapted to pick up the bundles and deliver them to the said elevator.

16. A bundle-loader having in combination an elevator for conveying the bundles to the wagon, and a horizontally-arranged pick-up mechanism for transferring the bundles to the elevator, such pick-up mechanism comprising a series of blades moving a slight distance above the ground and projecting forwardly in the direction of their movement so as to adapt them to lift the bundles from the ground.

17. The bundle-loader having in combination an elevator arranged transversely of the line of draft so as to adapt it to deliver bundles into a wagon located at the side of the loader, and a horizontal pick-up mechanism consisting of a series of blades moving in the direction of the draft and a slight distance above the ground and adapted to deliver the bundles to said elevator, a framework supporting said elevator and pick-up mechanism, and carrying and driving wheels.

18. A bundle-loader having in combination an elevator arranged across the line of draft and having one end lifted so as to adapt it to deliver the bundles into a wagon located at the side of the loader, a frame for supporting said elevator, driving and carrying wheels upon which the frame is mounted and from which the elevator is driven, a pick-up mechanism extending across the line of draft and having blades moving in line with the draft and acting to lift the bundles from the ground and deliver them to said elevator, and draft devices attached to said elevator-frame at one side of the pick-up mechanism.

810,381. TOOL-GRINDING DEVICE. JOHN RIDDELL and CASPER C. M. MORTENSEN, Schenectady, N. Y. Filed Aug. 3, 1905. Serial No. 272,347.



Claim.—1. In a device for grinding tools having a series of teeth movable in a definite path, the combination with the grinding-wheel and its driving means, of means controlled by the movement of the tool operated upon for causing the grinding-wheel to move toward each tooth as it passes said wheel.

2. In a device for grinding tools having a series of teeth movable in a definite path, the combination of a movable bearing-block in which the shaft of the grinding-wheel is journaled, and means controlled by the movement of the tool operated upon for moving said bearing-block whereby the grinding-wheel is caused to traverse each tooth of the tool at an angle to its path of motion.

3. In a device for grinding tools having a series of teeth movable in a definite path, the combination of a movable block in which the shaft of the grinding-wheel is journaled, and a controller-lever operatively connected to said block and extending into the path of the teeth to be actuated thereby, whereby the grinding-wheel is caused to traverse each teeth of the tool at an angle to its path of motion.

4. In a device for grinding tools having a series of teeth movable in a definite path, the combination of an oscillating bearing-block in which the shaft of the grinding-wheel is journaled eccentrically to the axis of oscillation, and means controlled by the movement of the tool operated upon for oscillating said bearing-block whereby the grinding-wheel is caused to traverse each tooth at an angle to its path of motion.

5. In a device for grinding tools having a series of teeth movable in a definite path, the combination of a bearing-support, an oscillating bearing-block carried thereby and in which the shaft of the grinding-wheel is journaled eccentric to the axis of oscillation, and an actuating-lever operatively connected to said block and extending into the path of said teeth whereby the grinding-wheel is caused to traverse each tooth at an angle to its path of motion.

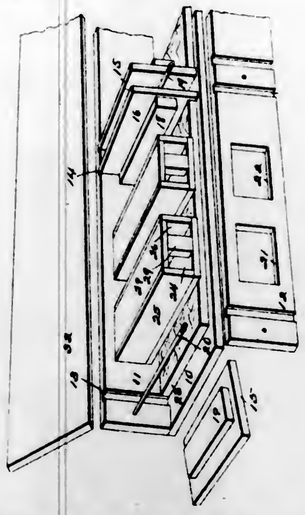
6. In a device for grinding tools having a series of teeth movable in a definite path, the combination of a bearing-support, an oscillating bearing-block carried thereby in which the shaft of the grinding-wheel is journaled eccentrically to the axis of oscillation, and an actuating-lever fulcrumed upon said bearing-support, operatively connected to said bearing-block and extending into the path of said teeth whereby the grinding-wheel is caused to traverse each tooth at an angle to its path of motion.

7. In a device for grinding tools having a series of teeth movable in a definite path, the combination of a bearing-support, an oscillating bearing-block carried thereby in which the shaft of the grinding-wheel is journaled eccentrically to the axis of oscillation, and an actuating-lever fulcrumed upon said support adjustably connected to said bearing-block and extending at one end into the path of said teeth.

8. In a device for grinding tools having a series of teeth movable in a definite path, the combination of a bearing-support, an oscillating bearing-block in which the shaft of the grinding-wheel is journaled eccentrically to the axis of oscillation, an actuating-lever fulcrumed upon said support, operatively connected to said block and extending at one end into the path of said teeth to be actuated in one direction thereby, and a spring for returning the parts of the device to normal position after each escapement of the actuating-lever from a tooth.

9. In a device for grinding tools having a series of teeth movable in a definite path, the combination of an oscillating bearing-block in which the shaft of the grinding-wheel is journaled eccentrically to the axis of oscillation, and an actuating-lever operatively connected to said block and comprising a rear section fulcrumed to some stationary part and a forward section connected thereto by a spring-pressed knuckle-joint.

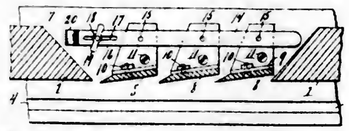
810,382. MOLD FOR CEMENT CONSTRUCTION-BLOCKS. MALVA M. ROBERTSON, Des Moines, Iowa. Filed Aug. 10, 1905. Serial No. 273,567.



Claim.—In molds for forming construction-blocks containing air-channels, cores comprising a base having on its upper surface two transverse cleats having their ends beveled said base engaging the companion openings in the longitudinal side of the mold; side pieces mounted upon the upper surface of the base of the core and engaging the sides of the openings in the longitudinal sides; a top extending between the side pieces of the core and engaging the upper surfaces of the opening in the longitudinal sides; two blocks mounted between the base and top of the core designed as a support for the top substantially as shown and described.

REISSUES.

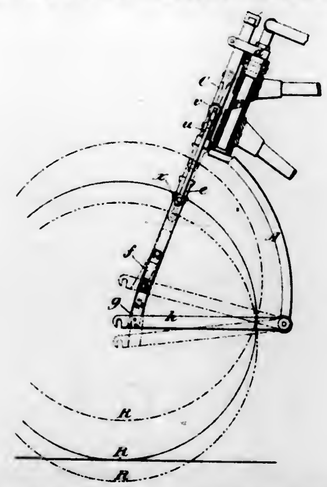
12,436. KRAUT-CUTTER. OLIVER E. THOMPSON, Ypsilanti, Mich. Filed June 29, 1905. Serial No. 267,669. Original No. 773,769, dated Nov. 1, 1904.



Claim.—1. In a kraut-cutting machine, the combination of a bed having a diagonal opening therein, knives set diagonally in said opening, brackets bolted to the face of said knives at their ends, said brackets having extending portions, pivot-pins passing through the extending portions of said brackets, said pivot-pins being of such length as to allow of a longitudinal movement of said knives as they tilt, a connecting-bar to which all of the brackets are independently pivoted, said bar being adjustable longitudinally to tilt the knives in unison and having a slot therein and a locking-bolt passing through said slot and engaging said frame.

2. The combination of a bed having a diagonal opening therein, knives set diagonally in said opening, brackets secured to said knives at their ends, pivot-pins passing through said brackets, said pins being of such length as to allow the knives to tilt and to have a slight longitudinally-reciprocatory movement, a connecting-bar to which all of the knives are independently pivoted, said bar being movable longitudinally to tilt the knives in unison, and means for locking said bar.

12,437. FRICTIONAL RETARDING MEANS FOR SPRING-VEHICLES. JULES M. M. TRUFFAULT, Paris, France, assignor of fifty-one one-hundredths to Edward Vassallo Hartford and forty-nine one-hundredths to George H. Hartford, both of Orange, N. J. Filed June 9, 1905. Serial No. 264,523. Original No. 695,508, dated Mar. 18, 1902.



Claim.—1. In a vehicle, the combination with a supporting-spring between the parts of the vehicle movable relatively to each

other, of rotating frictional means between the parts which provides a yielding resistance to movement, said means producing a retarding effect on the reaction of the spring, substantially as described.

2. In a vehicle, the combination with the wheel thereof, the frame carried by said wheel and a spring interposed between said wheel and frame, of rotating frictional mechanism which provides a yielding resistance to the movements of the part, said means serving to materially and uniformly exert a retarding effect on the said movements of the parts in both directions, substantially as described.

3. A retarding device for vehicle-springs comprising rotating friction members, adjustable clamping means, and means for connecting the rotating members to the parts of a vehicle movable relatively to each other, substantially as described.

4. A retarding device for vehicle-springs, comprising a plurality of friction members, means for regulating the pressure between said members, and arms for connecting the said members to the parts of a vehicle movable relatively to each other, so that the movement of the friction members is less than the relative movement of the spring-separated parts, substantially as described.

5. A retarding device for vehicle-springs comprising a plurality of friction members, adjustable means for regulating the pressure between said members, and operating means for connecting said members to the parts of a vehicle between which the springs are interposed, the contacting area of the friction-surfaces of said members being substantially unvarying and uniform in extent irrespective of the relative position of said members, substantially as described.

6. A retarding device for vehicle-springs comprising a pair of rotating friction members, friction material between said members, a clamping-bolt for holding the parts together, and arms for connecting said friction members to the parts of the vehicle between which the springs are interposed, substantially as described.

7. A retarding device for vehicle-springs, comprising a plurality of friction members, means for regulating the pressure between said members, and arms for connecting the said members to the parts of a vehicle movable relatively to each other, the parts being so arranged that the movement of the friction members is less than the relative movement of the spring-separated parts, and a hinged connection at the outer end of one of said arms, substantially as described.

8. A retarding device for vehicle-springs comprising a pair of rotating friction members, friction material between said members, a clamping-bolt for holding the parts together and arms for connecting said friction members with the parts of the vehicle between which the springs are interposed, and a hinged connection on the outer end of one of said arms, substantially as described.

9. In a vehicle, the combination with a supporting-spring between the parts of the vehicle movable relatively to each other, of a plurality of friction members, means for regulating the pressure between said members, and means for connecting the friction members to the vehicle, the said members being so arranged as to produce a retarding effect upon the action of the spring and the contacting area of the friction-surfaces of the said members being substantially uniform and unvarying in extent, irrespective of the relative positions of the parts, substantially as described.

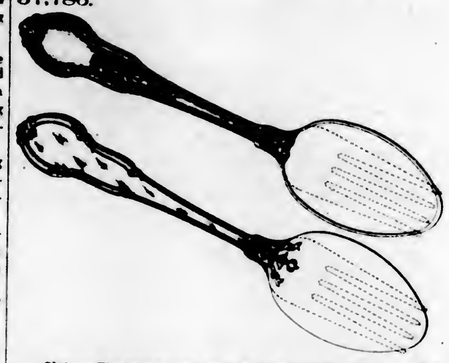
10. In a vehicle, the combination with a supporting-spring between the parts of the vehicle movable relatively to each other, of a plurality of friction members, means for regulating the pressure between said members, and means for connecting the friction members to the vehicle, the said members being so arranged as to produce a retarding effect upon the action of the spring, and the connecting means being arranged so that the movement of the friction members is less than the relative movement of the spring-separated parts, substantially as described.

11. In a vehicle, the combination with the wheel, the frame, the arms pivoted to the frame at one end, and the spring between said arms and frame, of the frictional pivot-bearings between the arms and the frame, each of these bearings comprising a bolt *o*, fixed in one of the parts and bearing cones *p* and *s*, and a nut *t*, the said cones and nut, and the coned leather washers *q* and *q'* in the eye of the other part, substantially as described.

DESIGNS.

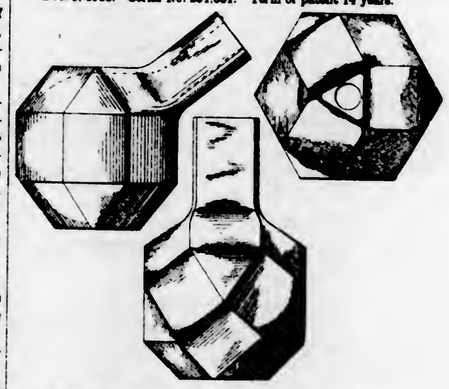
37,786. HANDLE OF SPOONS, FORKS, OR SIMILAR ARTICLES. WILLIAM C. GORHAM, Providence, R. I., assignor to Gorham Manufacturing Company, Providence, R. I. Filed Dec. 6, 1905. Serial No. 290,662. Term of patent 14 years.

37,786.



Claim.—The ornamental design for the handle of a spoon, fork or similar article, as shown.

37,787. BOTTLE. SAMUEL O. CARRUTHERS, Portland, Me. Filed Dec. 2, 1905. Serial No. 291,001. Term of patent 14 years.



Claim.—The ornamental design for a bottle, as shown.

37,788. CARD-CASE OR SIMILAR ARTICLE. ALFRED SCHICKERLING, New York, N. Y., assignor to Schickerling Brothers & Company, New York, N. Y., a Corporation of New York. Filed Dec. 9, 1905. Serial No. 291,155. Term of patent 7 years.

Claim.—The ornamental design for a card-case or similar article, as shown.

37,789. BACK FOR PLAYING-CARDS. SAMUEL N. BARKER, Kalamazoo, Mich. Filed Nov. 9, 1905. Serial No. 286,615. Term of patent 14 years.

Claim.—The ornamental design for a back for playing-cards, as shown.

TRADE-MARKS

PUBLISHED JANUARY 16, 1906.

The following trade-marks have been adjudged entitled to registration under the act of February 20, 1905, and are published in compliance with section 6 of said act. Said section provides:

"Any person who believes he would be damaged by the registration of a mark may oppose the same by filing notice of opposition, stating the grounds therefor, in the Patent Office within thirty days after the publication of the mark sought to be registered, which said notice of opposition shall be verified by the person filing the same before one of the officers mentioned in section two of this act. If no notice of opposition is filed within said time the Commissioner shall issue a certificate of registration therefor, as hereinafter provided for."

Marks which are stated to have been "Used ten years" are registrable under the last proviso of section 5 of said act, which is as follows:

"And provided further, That nothing herein shall prevent the registration of any mark used by the applicant or his predecessors, or by those from whom title to the mark is derived, in commerce with foreign nations or among the several States, or with Indian tribes, which was in actual and exclusive use as a trade-mark of the applicant or his predecessors from whom he derived title for ten years next preceding the passage of this act."

Section 14 of said act provides for the following fee:

"On filing notice of opposition to the registration of a trade-mark, ten dollars."

SER. No. 1,122. HORSESHOES AND HORSESHOE-CALKS. ROWE PATENT SQUARE SHOULDER SHOE CALK CO., Hartford, Conn. Filed Apr. 11, 1905. Used ten years.

The representation of a horseshoe having four square-shouldered horseshoe-calks and three square-shouldefed horseshoe-calks arranged within the horseshoe.

SER. No. 1,600. PLAYING-CARDS. THE UNITED STATES PLAYING CARD CO., Cincinnati, Ohio. Filed Apr. 15, 1905.

CIRCUS

The word "CIRCUS."

SER. No. 1,602. PLAYING-CARDS. THE UNITED STATES PLAYING CARD CO., Cincinnati, Ohio. Filed Apr. 15, 1905.

HUSTLING JOE

The words "HUSTLING JOE."

SER. No. 1,610. PLAYING-CARDS. THE UNITED STATES PLAYING CARD CO., Cincinnati, Ohio. Filed Apr. 15, 1905.

LITTLE-DUKE

The word "LITTLE-DUKE."

SER. No. 1,849. SOLID AND LIQUID SOAPS. EDWARD A. OLDS, New York, N. Y. Filed Apr. 17, 1905. Used ten years.

Packer's

The word-symbol "PACKER'S."

SER. No. 1,928. CONDENSED MILK. THE KENNEWEG COMPANY, Cumberland, Md. Filed Apr. 17, 1905.

SER. No. 1,928.

The representation of a star of solid color and the words "STAR BRAND CONDENSED MILK."

SER. No. 3,318. LARYNGOSCOPES. WILLIAM BORKEL AND COMPANY, Philadelphia, Pa. Filed Apr. 27, 1905.

The letter "B" inclosed in a circle.

SER. No. 3,465. INTERNAL REMEDIES AND A REMEDY IN THE FORM OF SUPPOSITORIES FOR ANEMIA, NEURASTHENIA, BRONCHITIS, INFLUENZA, PULMONARY TUBERCULOSIS, CONVALESCENCE, VAGINITIS, LEUCORRHEA, ENDOMETRITIS, METRITIS, URETHITIS, HYPERTROPHY, SUBINVOLUTION, ULCERATION, AND GONORRHEA. THE KAHAMA CHEMICAL CO., St. Louis, Mo. Filed Apr. 28, 1905.

Kahama

The word "KAHAMA."

SER. No. 4,382. STOVES, RANGES, FURNACES, AND PARTS THEREOF, INCLUDING GRATES AND GRATE-BARS. SCRANTON STOVE WORKS, Scranton, Pa. Filed May 5, 1905.

The rim of a cog-wheel surrounding the representation of the Western Hemisphere. Extending across the center of the cog-wheel and hemisphere is a sectional representation of a grate-bar, upon which is the word "DOCKASH."

SER. No. 4,389. DEVICES FOR USE IN APPLYING ELECTRICITY TO THE HUMAN BODY FOR CURATIVE PURPOSES. JOHN WILSON GIBBS, New York, N. Y. Filed May 5, 1905.

ELECTRICURA

The word "ELECTRICURA."

SER. No. 4,578. TOILET-PINS. DINKELSPIEL, RAFFLOER & Co., New York, N. Y. Filed May 6, 1905.

QUEEN'S OWN

The words "QUEEN'S OWN."

SER. No. 4,804. GELATINOUS ELASTIC CAPSULES CONTAINING LIQUID OR SOLID MEDICINAL INGREDIENTS. HANCE BROS. & WHITE, Philadelphia, Pa. Filed May 9, 1905.

SOLULES

The word "SOLULES."

SER. No. 4,880. LIQUID EXTRACT OF SMOKE FOR PRESERVING MEATS. B. KRAUSER & BROTHER, Milton, Pa. Filed May 9, 1905.

The representation of a suspended string of hams with a man in the act of applying a liquid to the hams with a brush with one hand and having a bucket in his other hand.

SER. No. 4,968. COTTON PIECE GOODS. TREMONT & SUFFOLK MILLS, Lowell, Mass. Filed May 10, 1905. Used ten years.

TREMONT

The arbitrarily-selected word "TREMONT."

SER. No. 5,293. WATCH-CHAINS, FOB-CHAINS, NECK-CHAINS, LORGNETTE-CHAINS, BOA-CHAINS, BRACELET-CHAINS, CHAIN-LINKED BRACELETS, KEY-CHAINS, CHATELAINES, AND CHAIN-TRIMMINGS. PARKS BROS. & ROGERS, Providence, R. I. Filed May 12, 1905.

The representation of a four-leaf clover having upon the petals respectively the letters and character "P B & R."

SER. No. 5,374. WINE. PLEASANT VALLEY WINE CO., Rheims, N. Y. Filed May 12, 1905.

Great Western

The words "GREAT WESTERN."

SER. No. 5,546. WHISKY. WEIL RICHOLD LIQUOR CO., Mobile, Ala. Filed May 13, 1905. Used ten years.

SER. No. 5,546.

A BIG HIT

The words "A BIG HIT."

SER. No. 5,706. AUTOGRAPHIC REGISTERS. THE CARTER-CRUME CO., LIMITED, Niagara Falls, N. Y. Filed May 15, 1905. Used ten years.

INVINCIBLE

The word "INVINCIBLE."

SER. No. 6,007. LAMP GLASSES AND GLOBES. MACBETH-EVANS GLASS COMPANY, Pittsburg, Pa. Filed May 18, 1905. Used ten years.

SANDOW

The word "SANDOW" inclosed in a diamond-shaped figure.

SER. No. 6,086. GUNS, RIFLES, PISTOLS, REVOLVERS, AND PARTS THEREOF. THE WEBLEY & SCOTT REVOLVER & ARMS CO., LD., Birmingham, England. Filed May 19, 1905.

The representation of a bullet in longitudinal section surmounted by a pair of wings.

SER. No. 6,288. WHISKY. WRIGHT & TAYLOR, Louisville, Ky. Filed May 23, 1905. Used ten years.

DUNMORE

The word "DUNMORE."

SER. No. 6,481. WHISKY. THE I. TRAGER CO., Cincinnati, Ohio. Filed May 24, 1905. Used ten years.

DEERFIELD

The word "DEERFIELD."

SER. No. 6,515. WHISKY. CRIGLER & CRIGLER, Covington, Ky. Filed May 24, 1905. Used ten years.

Woodland

The word "WOODLAND" and a monogram composed of the letters and character "C & C" inclosed within a shield design with stems and heads of grain below and at each side of the shield.

SER. No. 6,521. WHISKY. I. MICHELSON & BROS., Cincinnati, Ohio. Filed May 24, 1905.

BONANZA KING

The words "BONANZA KING" and the fanciful bust picture of a man inclosed in an oval.

SER. No. 6,585. WHISKY. FREIBERG, MEYER & CO., Cincinnati, Ohio. Filed May 25, 1905. Used ten years.

KENTUCKY PLUME

The words "KENTUCKY PLUME" and the monogram "F M & Co" on a dark circular background.

SER. No. 6,631. WHISKY. MAX E. POLLASKY, Buffalo, N. Y. Filed May 25, 1905. Used ten years.

Old Diamond Wedding

The words "OLD DIAMOND WEDDING" and a monogram composed of the letter and abbreviation "S Co" within a diamond-shaped outline.

SER. No. 6,947. SHEET AND PICTURE GLASS. SIMON BACHE & COMPANY. New York, N. Y. Filed May 30, 1905.

The representation of a heart.

SER. No. 7,117. RIBBON, RIBBON BOWS, AND GALLOON BINDINGS FOR USE ON SLIPPERS. MARY B. MARTINE, New York, N. Y. Filed May 31, 1905.

A monogram composed of the letters "M B M" inclosed by two concentric oval lines between which appear the number and words "365 DAYS IN ADVANCE OF ALL COMPETITORS."

SER. No. 7,157. POTTERY, EARTHENWARE, AND CHINA. DOULTON & CO., LIMITED, Lambeth, London, England. Filed June 1, 1905. Used ten years.

DOULTON

The word "DOULTON."

SER. No. 7,158. POTTERY, EARTHENWARE, AND CHINA. DOULTON & CO., LIMITED, Lambeth, London, England. Filed June 1, 1905.

DECISIONS

OF THE

COMMISSIONER OF PATENTS

AND OF

UNITED STATES COURTS IN PATENT CASES.

COMMISSIONER'S DECISIONS.

EX PARTE HAYES.

Decided October 26, 1905.

1. INVENTION—WATERPROOF CASING UPON ELECTROMAGNET.

Held that the provision of a waterproof casing upon an electromagnet which is to be used under water does not involve invention.

2. SAME—NON-MAGNETIC CASING UPON ELECTROMAGNET.

Held that the use of non-magnetic material for the casing of an electromagnet by one who does not claim to be the discoverer of the fact that magnetic material would interfere with the proper operation of the device cannot be regarded as patentable.

3. ANTICIPATION—INCASED ELECTROMAGNET.

An electromagnet having a waterproof casing of non-magnetic metal *Held* to be without patentable novelty, in view of a patent disclosing an electromagnet with a moisture-proof casing of non-magnetic material.

APPEAL from Examiners-in-Chief.

WATERPROOF ELECTROMAGNET.

Mr. Lincoln Sonntag and *Messrs. H. C. Evert & Co.* for the appellant.

ALLEN, *Commissioner:*

This is an appeal from the decision of the Examiners-in-Chief affirming the rejection by the Primary Examiner of the following claim:

In a waterproof electromagnet covers of non-magnetic metal inclosing the coils or windings of such magnet, substantially as and for the purposes described.

The reference is patent to Wellman December 10, 1895, No. 551,020.

The device to which the claim is drawn is an electromagnet provided with a waterproof casing of non-magnetic metal. The casing is made of non-magnetic material to avoid interference with the proper operation of the magnet. It is made waterproof, so that the magnet may be used under water without injurious effect upon its coils. I am of the opinion, aside from the reference which has been cited in this case, that the provision of a waterproof casing upon an electromagnet which is to be used under water does not involve invention and that the use of a non-magnetic material for the casing by one who does not claim to be the discoverer that magnetic material used for such purpose would interfere with the proper operation of the device cannot be regarded as patentable.

Moreover, the patent to Wellman, to which reference has been made, discloses an electromagnet the main feature of which is stated to be that it is so constructed that "it can be used on outside work, it being thoroughly protected from the atmosphere." It is also stated in Wellman's specification that "surrounding the magnet is a shell D extending from the top plate A' to a non-magnetic bottom plate A," and that "the several parts of the magnet are fastened securely together preventing moisture from gaining access to the interior of the magnet." It is further stated in said specification that the shell D is preferably made of non-magnetic material. The use of non-magnetic metal as the non-magnetic material of the Wellman magnet is clearly a mere matter of selection from various materials which might obviously be used and does not involve invention. If the Wellman magnet as ordinarily constructed would leak upon use under water, the joints thereof could certainly be packed and tightened to make the casing entirely waterproof in such use without the exercise of more than mechanical skill. The claim appealed, as well as the claim proposed on the appeal as a substitute therefor, is not patentable over the Wellman device.

The decision of the Examiners-in-Chief affirming the rejection by the Primary Examiner of the claim appealed is affirmed.

CARNELL *v.* GLASGOW *v.* COOK.

Decided December 18, 1905.

INTERFERENCE—DISSOLUTION—RIGHT TO MAKE CLAIM AND INTERFERENCE IN FACT CONFUSED.

The contention by an interferant that the opposing parties do not have a construction responding to certain language in the issue is one relating to the right to make the claim and not to interference in fact.

APPEAL on motion.

CARBURETERS.

Mr. Alfred M. Allen and *Mr. Paul Finckel* for Carnell.

Messrs. Bakewell & Cornwall for Glasgow.

Mr. E. G. Siggers for Cook.

ALLEN, *Commissioner:*

This is an appeal by Carnell from a decision of the Primary Examiner holding that there is an interference in fact as to all parties on the single count forming the subject-matter of the interference, that the claim is patentable to Glasgow and Cook, and that they had a right to make the same.

That part of the appeal relating to the right to make the claim and to the patentability thereof is dismissed, because there is no appeal from a favorable decision on those questions.

The argument on the question of interference in fact relates to that part of the claim couched in the words "and means for adjusting the active length of the spring." After quoting the issue appellant's brief states:

It is claimed on behalf of Carnell that neither Glasgow or Cook show any means of adjusting the active length of the spring.

In other words, the contention made is not that the terms quoted cannot be read on the different constructions with the same meaning, but that these terms cannot be properly used at all by the opposing parties. It is evident that the question presented is one going to the right to make the claim and not to the question of interference in fact.

The appeal is dismissed.

EX PARTE CLUETT, PEABODY & COMPANY.

Decided December 14, 1905.

1. TRADE-MARKS—PUBLICATION—REJECTION THEREAFTER WITHOUT OPPOSITION.

The Examiner may refuse registration after the publication of a trade-mark under section 6 of the Tade-Mark Act even where no notice of opposition is filed.

2. SAME—SAME—SECTION 6 CONSTRUED—PERMISSIVE, NOT MANDATORY.

The provision in section 6 of the act that the Commissioner "shall issue a certificate of registration" in case no notice of opposition is filed is permissive and is not mandatory.

3. SAME—SAME—SAME—RIGHT TO REJECT—INTENT.

Section 6 was intended to provide an additional means for determining the right of the applicant to registration, and not for the purpose of cutting off the right of the Office to consider and act upon any and all legitimate questions as to the applicant's right.

4. SAME—SAME—SAME—CONSIDERATION OF EVIDENCE.

It was not the intent of section 6 that this Office should reject an applicant upon evidence presented by one opposing and disregard the same evidence if discovered by its own efforts.

ON PETITION.

TRADE-MARK FOR GARMENTS.

Messrs. Mosher & Curtis for the applicants.

ALLEN, *Commissioner:*

This is a petition from the action of the Examiner of Trade-Marks in reëxamining and rejecting this application after publication in the OFFICIAL GAZETTE for the purpose of permitting opposition by interested parties under the provisions of section 6 of the act of February 20, 1905.

It appears that this application was duly considered by the Examiner and was passed for publication on May 18, 1905, and was published on June 6, 1905. No opposition was filed against registration; but the Examiner concluded thereafter that there was a statutory bar to the registration of the mark claimed and for that reason wrote a letter rejecting the application. This petition does not raise the question whether the Examiner was right in concluding that there is a statutory bar, but raises the question whether he has authority under the statutes to reject an application after publication, even where a statutory bar exists.

Section 6 of the act of February 20, 1905, after providing for publication of the mark for purposes of opposition, provides that—

> If no notice of opposition is filed within said time the Commissioner shall issue a certificate of registration therefor, as hereinafter provided for.

The question for determination is whether the word "shall" appearing in this clause is mandatory and absolutely precludes the rejection of an application after publication unless notice of opposition is filed.

In *Railroad Company* v. *Heckt* (95 U. S., 168) the Supreme Court said:

> As against the Government, the word "shall," when used in a statute, is to be construed as "may," unless a contrary intention is manifest.

In volume 25 of the *American and English Encyclopedia of Law* (p. 634) it is said:

> In all cases the question whether "shall" will be interpreted in the sense of "may" or will be construed as mandatory depends upon the intention of the legislature.

The intention of the Legislature, as gathered from the entire Trade-Mark Act and from the particular consideration of section 6 thereof, is clearly that the word "shall" is to be understood as permissive and not as mandatory. The purpose of the publication referred to in section 6 is to permit others to present to this Office evidence which will enable it to determine whether or not the application is entitled to registration. In other words, it merely provides a method of securing evidence upon which this Office is to base its action. It provides this method, because this Office has not the machinery for obtaining otherwise and by its own efforts all information bearing upon the right of the applicant to registration. It is perfectly clear, however, that it was not the intention of Congress to provide that this Office should disregard evidence which it secured by its own efforts and should reject the application upon exactly the same evidence if it is presented by some one interested in opposing the registration. This, however, would be the result of sustaining the petitioners' contention as to the meaning of the word "shall" in section 6 of the act.

It must be held that section 6 was intended to provide additional means for determining the right of the applicant to registration and not for the purpose of cutting off the right of this Office to consider and act upon any and all legitimate questions as to the applicant's right.

The petition is denied.

W. A. GAINES & CO. *v.* CARLTON IMPORTATION CO.

Decided December 18, 1905.

1. TRADE-MARKS—LACK OF INTERFERENCE—"OLD JAY" AND "OLD CROW."

A mark consisting of "Old Jay" and the representation of a jay does not so nearly resemble the words "Old Crow" and the representation of a crow as to mislead the public or deceive purchasers.

2. SAME—CONSTITUTIONALITY OF LAW—QUESTION FOR COURTS.

The question as to the constitutionality of the trade-mark law will not be determined upon opposition to the registration of a trade-mark, but will be left to the courts for determination.

APPEAL from Examiner of Interferences.

TRADE-MARK FOR WHISKY.

Mr. Jas. L. Hopkins and *Mr. John S. Barker* for Gaines & Company.

Mr. Frederic B. Keefer for Carlton Importation Company.

ALLEN, *Commissioner:*

This is an appeal by W. A. Gaines & Company from the decision of the Examiner of Interferences dismissing their notice of opposition to the registration of a trade-mark by the Carlton Importation Company.

The applicant's trade-mark consists of the representation of a jay bird perched upon the branch of a tree having upon each side "Old J" and beneath the words "Old Jay Rye." W. A. Gaines & Company filed notice of opposition to the registration of this mark on the ground that they are the owners of a mark which so nearly resembles the applicant's mark that confusion is likely to result. They say that they are "the sole and exclusive owners of the trade-mark for whisky consisting of the words 'Old Crow,' accompanied by with the picture of a crow."

The Carlton Importation Company filed a "demurrer" to the notice of opposition, which "demurrer" was sustained by the Examiner of Interferences on the ground that it is apparent upon the face of the papers that there is no such similarity between the marks as to cause confusion.

Both marks include the word "old," and both include the representation of a bird; but there the similarity ends. The jay, as disclosed in the application and in the specimens accompanying it, is entirely different in appearance from a crow and could by no possibility be mistaken therefor. The name "jay" is entirely different in sound from "crow" and suggests a different idea. If there is to be any confusion between the marks, it must be because of the association of the word "old" with the name of a bird. I am satisfied, however, that this one point of similarity is not sufficient to confuse the public nor to mislead purchasers exercising ordinary care.

The appellants here have raised the question as to the constitutionality of the Trade-Mark Act of February 20, 1905; but it is deemed unnecessary to discuss that matter. The question of constitutionality should be raised and determined in the courts upon registrations made under that act.

The Examiner was right in dismissing the opposition, and his decision is affirmed.

EX PARTE BERG.

Decided December 21, 1905.

1. AFFIDAVITS UNDER RULE 75—NOT ADMITTED AFTER FINAL REJECTION.

After a claim has been finally rejected on several references an antedating affidavit under Rule 75 tending to overcome one of the references cannot be admitted.

2. REOPENING EX PARTE CASE—ALLEGED STATEMENT OF NEW REASONS FOR REJECTION BY EXAMINER.

Where antedating affidavits under Rule 75 to overcome one of several references are filed after final rejection and in refusing consideration to such affidavits the Examiner states that the rejection could be sustained on the references other than the one attempted to be overcome, *Held* that this statement of the Examiner is not a statement of new reasons for rejection and does not operate to reopen the case.

ON PETITION.

HAMMOCKS OR COTS.

Mr. Henry A. Seymour for the applicant.

ALLEN, *Commissioner:*

This is a petition from the action of the Primary Examiner refusing to admit affidavits filed under Rule 75 after the case was under final rejection.

In the prosecution of the case the claims were rejected on certain references. The applicant amended them, after which they were rejected on the same references, together with an additional reference, which was apparently cited to meet the amendment. Thereafter reconsideration of the case was requested, which was given, and the claims were finally rejected. Applicant then sought to overcome the final rejection by filing affidavits antedating the reference last cited. The Examiner refused to admit the affidavits, on the ground that the consideration of the case was closed. In the letter refusing admission to or consideration of these affidavits the Examiner also stated that the claims were met in the references cited outside of this additional reference which the affidavits sought to overcome. Applicant urges that this statement that the claims were met by the other references alone was, in effect, a citation of new reasons for rejection and operated to reopen the case. This petition therefore presents two questions for decision—the propriety of the refusal to admit the affidavits and whether or not the Examiner unintentionally reopened the case.

As to the first question, it is thought that the Examiner properly refused to admit the antedating affidavits after final rejection. If the affidavits were admitted, the Examiner would have the burden of considering their sufficiency at least once, and perhaps twice, and if they were found to overcome the reference the final action would have to be withdrawn and probably new references cited in lieu of the prior ones, thus fully reopening the case. It might be urged that the presumption that other references might be found to take the place of the old cannot be indulged, because the Examiner is bound to cite in the first action the best references at his command; but it would not be practicable always to cite every anticipating reference, particularly as in this case, where the reference was cited to meet only one of several features.

The practice on the question here presented should be the same as that in filing amendments after final rejection. Therefore antedating affidavits should not be admitted without a duly-verified showing why they were not earlier presented. As well stated by the Examiner:

> The practice of the Office * * * requires the applicant in prosecution of his case to present at each step the best and all the reasons why the claims should be allowed. If references can be overcome by affidavits they should be presented at once for consideration by the Office, so that the case may, upon each action, take a decisive step toward completion.

In an attempt to comply with the requirements of the Examiner applicant made a verified showing as to why the affidavits were not earlier presented. In this showing it is stated that after the first rejection the advisability of filing the antedating affidavits was considered, but that the applicant refused to execute the affidavits, because it was unnecessary, as the references were not believed to meet the claims. This showing appears to constitute more of a reason for refusing the admission of the affidavits than for admitting them. If the applicant after apparently seeing the necessity of filing the affidavits deliberately refuses to file them and chooses to stand on the ground that the references do not meet the claims, he should abide by his election. To permit an applicant to exhaust one line of prosecution and then select another is to permit piecemeal action, which is not and should not be favored.

The second question presented is: Did the statement of the Examiner in his refusal to admit the affidavits, to the effect that the claims were met in the references other than that which it was attempted to antedate, amount to a reopening of the case? It is believed that it did not. The references cited in the case were cited to show the prior state of the art, and if at any time, even after final rejection, the Examiner should choose to rely on a part of that prior art instead of the whole of it as an anticipation no valid objection could be taken to such a course. A different view of the effect or pertinency of certain devices in the prior art does not constitute a new reason for rejection. There was therefore no impropriety in this expression of opinion of the Examiner after final action on the application, and it did not act to reopen the case.

The petition is denied.

THULLEN v. YOUNG AND TOWNSEND.

Decided December 21, 1905.

LIMIT OF APPEAL—MOTION TO EXTEND AFTER LIMIT EXPIRES—VERIFIED SHOWING.

After the expiration of a limit of appeal a motion to extend the limit will not be entertained except upon a verified showing in excuse for the delay.

ON PETITION.

SIGNALING SYSTEM.

Mr. George E. Cruse for Thullen.

Mr. George H. Benjamin for Young and Townsend.

ALLEN, *Commissioner:*

This is a petition by Young and Townsend asking that the Examiners-in-Chief be advised "that they should take jurisdiction of an appeal" from the decision of a Primary Examiner dissolving an interference filed more than three months after the limit of appeal had expired.

The limit of appeal expired July 5, 1905, and appeal was not taken until October 17, 1905. Under such circumstances in order to get consideration of the appeal by the Examiners-in-Chief a motion should have been brought to extend the limit of appeal to include the appeal taken October 17. The present petition will therefore be treated as a motion to extend the limit of appeal.

It is the well-settled practice of this Office, as announced in *Kletsker and Goesel* v. *Dodson* (109 O. G., 1336; C. D., 1904, 100) and other decisions, that an appeal filed after the expiration of the limit of appeal will not be entertained except upon a verified showing why it was not presented in proper time. Some reason for the delay is stated in support of the motion now presented; but it is not verified, and therefore will not be considered.

The motion is dismissed.

LINDSTROM v. LIPSCHUTZ.

Decided December 22, 1905.

1. INTERFERENCE—OFFICE CANNOT COMPEL WITNESS TO ANSWER—SUPPRESSION OF TESTIMONY.

The testimony of a witness may be suppressed on account of his refusal to furnish material evidence; but the Office has no machinery for compelling him to furnish such evidence.

2. SAME—STRIKING OUT ALLEGED SUPPLEMENTAL BRIEF.

Where at the hearing of a motion to compel a witness to answer certain questions or to suppress his deposition the interference was suspended for ten days to permit the parties to come to some agreement and a paper was thereafter filed in the case, in accordance with the agreement of counsel, to show that no agreement could be reached, *Held* that such paper will not be stricken out upon the allegation that it is a supplemental brief filed in violation of the rules.

SAME—EVIDENCE—CANNOT BE ADMITTED MERELY FOR INSPECTION OF OFFICE.

A letter which a party refused to introduce into evidence on the ground that it related to a secret invention cannot be filed in the Office merely for the inspection of the various tribunals who may consider the case. If the letter did not tend to affect the final judgment, there would be no reason for considering it, and if it did the opposing party would have a right to inspect and meet it as he might see fit.

ON MOTION.

DUMPING-CARS.

Mr. William H. Finkel and *Messrs. Babcock & Byrnes* for Lindstrom.

Mr. Charles G. Hawley and *Mr. Wallace Greene* for Lipschutz.

ALLEN, *Commissioner:*

This case presents for consideration a motion by Lindstrom, the opposing party, to place in evidence a certain private letter alleged to be material and a motion to suppress a supplemental brief filed by Lindstrom on this question, combined with a motion to suppress the entire deposition of Lindstrom, together with the exhibits referred to in said deposition, because of his failure to produce said letter and to answer other material and relevant interrogatories.

Motions to suppress testimony should be brought before and determined by the Examiner of Interferences in the first instance, and therefore this part of the motion cannot be entertained.

As to the production in evidence of the letter in question, it is well settled that this Office has no machinery for compelling a witness to answer or to produce evidence of any kind. The Office may at final hearing strike out or refuse to consider the testimony of a witness who refuses to furnish material evidence; but if a party is not satisfied with this remedy he must apply to a Federal court for the proper order compelling the witness to furnish the desired evidence.

In regard to striking out the supplemental brief it is to be said that the paper in question is not, strictly considered, a supplemental brief, although it is so entitled. At the hearing granted on the motion to compel the production of the letter it was stated that the Commissioner was without power to grant such an order, and it was suggested that possibly some agreement might be reached by the parties without going into court, and proceedings were therefore suspended for ten days for this purpose. It is stated by counsel for Lindstrom in his brief that after the hearing it was agreed between associate counsel that if their principals could not agree upon some settlement of the questions at issue counsel for Lindstrom should file in the case a statement to this effect. The so-called supplemental brief seems to have been filed merely for the purpose of carrying out this agreement, and whether this paper was filed in pursuance of any agreement or not is immaterial, as it was evidently filed for the purpose of calling attention to the fact that the party in whose behalf it was filed (Lindstrom) refused to put the letter in evidence or any part of it beyond that which was read by the witness during his cross-examination. This being the purpose of the paper, it is not objectionable.

The letter in question is a letter which was written by Lindstrom to his attorney. A certain portion of the letter was read by the witness on cross-examination; but he refused to read it all or to put it in evidence, on the ground that it related to other inventions, which it was his right to maintain in secrecy, according to the provisions of section 4008 of the Revised Statutes. While refusing to divulge the entire contents of the letter, the witness states that he is perfectly willing and, in fact, would prefer to submit the letter to the inspection of all the tribunals of this Office in order that they may satisfy themselves of its contents. The only reason for the consideration of the letter in any way is because of its probable effect in changing the final judgment, and it is obvious that if this should be its effect the opposing party would have a right to inspect it and to object to it or meet it by other evidence, as he might see fit. It is neither necessary nor proper to inspect a letter which is not properly in evidence in the case, and it cannot therefore be filed in the manner suggested.

The motion for an order compelling the witness to produce the letter in question and to answer certain questions and asking that the deposition of such witness be suppressed is dismissed. The motion to strike out the supplemental brief is denied.

EX PARTE RICHMOND.

Decided December 23, 1905.

1. AFFIDAVITS—FILED AFTER FINAL REJECTION AND DECISION ON APPEAL.

Where affidavits are presented after final rejection of the claims and decision by the Examiners-in-Chief on appeal purporting to show that the rejection of the claims was improper and it is alleged that the affidavits are based upon experiments made after the decision of the Examiners-in-Chief, *Held* that the experiments should have been made and the affidavits filed before the case was closed before the Primary Examiner and that the affidavits would not be admitted.

2. REOPENING CASE AFTER FINAL REJECTION—FOR NEW EVIDENCE—SHOWING REQUIRED.

Where the party fails to make his demonstration and to submit his evidence in response to the original rejection before prosecuting his case to final rejection, the case will not thereafter be reopened except upon showing of good and sufficient reasons why the evidence whose admission is sought was not earlier presented.

ON PETITION.

THERAPEUTIC APPARATUS.

Mr. F. B. Fetherstonhaugh for the applicant.

ALLEN, *Commissioner:*

This is a petition that the above-entitled application be reopened for the admission of affidavits presented for the first time after decision upon appeal to the Examiners-in-Chief.

The case was rejected by the Primary Examiner on the ground of inoperativeness. An argument was made in response to this rejection, in view of which the case was reconsidered and finally rejected. Appeal was then taken to the Examiners-in-Chief, who affirmed the rejection by the Primary Examiner. The applicant thereupon brought this petition, averring that since the decision of the Examiners-in-Chief experiments have been performed demonstrating the operativeness of the invention and requesting that the application be reopened for consideration by the Primary Examiner of affidavits to said experiments. The proper time for demonstrating the operativeness of the invention and presenting evidence thereof was in response to the original rejection for inoperativeness and before the prosecution of the case before the Primary Examiner had been closed by final rejection. Where the party fails to make his demonstration and to submit his evidence in response to the original rejection before prosecuting his case to final rejection, the case will not thereafter be reopened except upon showing of good and sufficient reasons why the evidence whose admission is sought was not earlier presented. No such showing is found in the present case.

The petition is denied.

LEMP v. RANDALL AND BATES v. THOMSON.

Decided December 26, 1905.

1. INTERFERENCE—MOTION FOR JUDGMENT ON RECORD—APPEAL.

Held that decisions of the Examiner of Interferences denying motions for judgment on the record should not be subject to review on appeal, as such decisions are not final determinations that judgment will not be rendered in favor of the moving parties.

2. SAME—SAME—SAME.

Denial of an appeal from decisions of the Examiner of Interferences refusing to render judgment on the record deprives the parties of no substantial right, while to permit appeals in such cases results in unnecessary delay, labor, and expense.

3. SAME—JUDGMENT ON RECORD.

Held that Rule 114 does not clearly and unmistakably require the Examiner of Interferences to render judgment against a party who has been called upon to show cause under that rule and who fails to take any action in response.

APPEAL on motion.

STEAM-GENERATING APPARATUS.

Mr. A. G. Davis and *Messrs. Lyons & Bissing* for Lemp.

Mr. Arthur F. Randall for Randall and Bates.

Mr. A. G. Davis and *Messrs. Lyons & Bissing* for Thomson.

ALLEN, *Commissioner:*

This is an appeal by Randall and Bates from the action of the Examiner of Interferences denying their motion that judgment be rendered against the party Lemp.

The Examiner of Interferences on May 12, 1905, issued an order stating that the preliminary statements of Lemp and Randall and Bates failed to allege dates of conception prior to the filing date of Thomson and giving notice that judgment would be rendered against Lemp and against Randall and Bates unless they should show cause on or before June 1, 1905, why such action should not be taken. On May 31, 1905, Randall and Bates brought a motion for dissolution, which was transmitted to the Primary Examiner on June 6, 1905, and proceedings were suspended pending determination thereof. On October 28, 1905, Randall and Bates brought their motion that judgment on the record be entered against Lemp in pursuance of the notice and order to show cause of May 12, 1905. The Examiner of Interferences pointed out that the motion of Randall and Bates for dissolution was based in part on the ground that Thomson had no right to the claims in issue and that the preliminary statement of Lemp did not fail to go back of the record date of Randall and Bates. He concluded that if upon the motion for dissolution pending it should be found that Thomson has, in fact, no right to claim the issue the question of priority between Lemp and Randall and Bates would be an open one before the Office and decided, for that reason, that judgment should not be rendered against Lemp at this time. It is from this decision that the present appeal is brought.

I am of the opinion, as was pointed out in the case of *The Gem Cutlery Company* v. *Leach*, (114 O. G., 2089,) that the decisions of the Examiner of Interferences denying motions for judgment on the record should not be subject to review on appeal. As stated in that case, such a decision is not a final one that judgment will not be rendered in favor of the party bringing the motion. Denial of an appeal in such cases as the present one deprives the parties of no substantial right, while to permit appeals in these cases results in unnecessary delay, labor, and expense.

While it is believed that the present appeal should not be entertained, I have nevertheless considered the contention that the refusal of the Examiner of Interferences to enter judgment against Lemp is in violation of Rule 114 sufficiently to satisfy myself that the rule does not clearly and unmistakably require the action sought by appellants. Appellants also allege that they will suffer hardship and

that confusion will result if their appeal is not entertained and the decision of the Examiner of Interferences reversed. I am unable, however, to see that such will be the case.

The appeal is dismissed.

DALTON *v.* HOPKINS *v.* NEWMAN.

Decided December 20, 1905.

STAY OF PROCEEDINGS—UNWARRANTED APPEAL—MOTION BY PARTY IDENTIFIED IN INTEREST WITH APPELLANT.

When a party to an interference who has no substantial standing therein takes an unwarranted appeal, *Held* that another party thereto who is identified in interest with the first-mentioned party would not be granted a suspension of proceedings pending decision upon said appeal in prolongation of previous extensive delay.

ON PETITION.

ADDING AND WRITING MACHINES.

Mr. J. D. Rippey and *Mr. G. R. Hamlin* for Dalton.

Mr. J. D. Rippey and *Mr. G. R. Hamlin* for Hopkins.

Messrs. Rector & Hibben for Newman.

ALLEN, *Commissioner:*

This is a petition by Hopkins for a stay of proceedings in the above-entitled interference.

The Examiner of Interferences refused to transmit to the Primary Examiner the motion of Dalton for dissolution of the interference. He also refused to order a stay of proceedings and fixed times for taking testimony, in accordance with which Hopkins's testimony-in-chief is to close on January 8, 1906. Dalton has taken an appeal from the decision of the Examiner of Interferences refusing to transmit his motion to dissolve, which appeal is fixed for hearing before me on January 4, 1906. Hopkins seeks a stay of proceedings pending a decision on the appeal, claiming that he should not be required to take testimony until it is finally decided that the interference is to go on. It appears that the filing date of Dalton is subsequent to that of Hopkins, as well as to that of Newman, and that Dalton filed no preliminary statement. The specific allegations of his motion for dissolution filed in response to the order to show cause why judgment should not be rendered against him relate solely to the question whether the interference should continue between himself and Newman. The motion contains, in addition to the specific allegations, the general allegation that there has been such irregularity in declaring the interference as will preclude proper determination of the question of priority of invention. No specific irregularity has been pointed out, and it must be presumed that this allegation of irregularity is merely a general statement, made under a loose practice recently in vogue, referring to the specific allegations that Newman has no right to claim the counts in issue. Under such circumstances the motion to dissolve is no answer to the order to show cause why judgment should not be rendered against Dalton as subsequent in date to the party Hopkins, and it appears that judgment was so rendered by the Examiner of Interferences. It further appears that the parties Dalton and Hopkins are one in interest in the prosecution of this interference. Dalton signed the preliminary statement in Hopkins's case as assignee therein, and Dalton and Hopkins are represented by the same attorneys. Under these circumstances no good reason is seen for granting a stay of proceedings. Dalton on the face of the record has no substantial standing in the interference, and Hopkins, identified with Dalton in interest, should not be permitted to prolong the extensive delay which has already occurred on account of Dalton's unwarranted appeal.

The petition is denied.

HEINTZELMAN AND CAMP *v.* VRAALSTAD AND DOYLE.

Decided December 27, 1905.

1. INTERFERENCE—DISSOLUTION—APPEAL ON MOTION—RIGHT TO CLAIM NOT CONSIDERED UNDER HEAD OF INTERFERENCE IN FACT.

Where it is contended upon appeal on motion to dissolve for non-interference in fact that a party has no right to make claims, *Held* that the question of right to make claims is different from that of interference in fact and will not be considered of such on appeal. (*Blackmore* v. *Hall*, 119 O. G., 2523.)

2. SAME—INTERFERENCE IN FACT.

Where, so far as the invention in issue is concerned, the same results are accomplished by substantially the same or equivalent means in the device of each party and the terms of the issue have the same meaning in each case, *Held* that there is interference in fact.

3. SAME—SAME—EFFECT OF DIFFERENCES IN THE DEVICES NOT INVOLVED IN THE ISSUE.

Where it is contended upon appeal on motion to dissolve for non-interference in fact that, in view of functions effected in appellees' apparatus which it is claimed are not effected in that of the appellants, the inventions claimed by the respective parties are essentially different, *Held* that the differences in function referred to related to specific differences in the devices to which the issue is limited and formed no basis for dissolution of the interference. (*Townsend* v. *Copeland* v. *Robinson*, 119 O. G., 2523.)

APPEAL on motion.

FIRE-BOXES.

Mr. J. Snowden Bell and *Mr. W. E. Schoenborn* for Heintzelman and Camp.

Mr. J. Nota McGill for Vraalstad and Doyle.

ALLEN, *Commissioner:*

This is an appeal by Heintzelman and Camp from the decision of the Primary Examiner denying their motion to dissolve the interference as to the ground of non-interference in fact.

Each count of the issue includes as an element "a fire-box which is unobstructed by arches or projections." The contentions of appellants are, in substance, first, that in view of the part marked "7" in Figure 1 of the appellees' drawing the appellees have no right to make a claim containing the limitation quoted, and, second, that in view of certain functions effected in appellees' apparatus in connection with the part "7" which, it is claimed, are not effected in appellants' apparatus, the inventions claimed by the respective parties are essentially different. The question of appellees' right to make the claims in issue is different from the question of interference in fact and will not be considered on this appeal. (*Blackmore* v. *Hall*, 119 O. G., 2523.) The functions effected in appellees' device in connection with the part 7, on which functions the appellants base their contention that the inventions in the two cases are essentially different, relate to specific differences in the devices of the respective parties to which the counts in issue are not limited and with which this interference has nothing to do. These differences afford no basis for holding that there is no interference in fact. (*Townsend* v. *Copeland* v. *Robinson*, 119 O. G., 2523.) So far as the invention in issue is concerned the same results seem to be accomplished by substantially the same or equivalent means in the device of each party, and the terms of the issue seem to have the same meaning in each case. Under these circumstances there is clear interference in fact.

The decision of the Primary Examiner refusing to dissolve the interference on the ground that there is no interference in fact is affirmed.

Drawings.

RULE 38.

38. When there are drawings the description will refer to the different views by figures and to the different parts by letters or numerals (preferably the latter).

RULE 52—EXTRACT.

(6) The different views should be consecutively numbered. Letters and figures of reference must be carefully formed. They should, if possible, measure at least one-eighth of an inch in height, so that they may bear reduction to one twenty-fourth of an inch; and they may be much larger when there is sufficient room. They must be so placed in the close and complex parts of drawings as not to interfere with a thorough comprehension of the same, and therefore should rarely cross or mingle with the lines. When necessarily grouped around a certain part, they should be placed at a little distance, where there is available space, and connected by short broken lines with the parts to which they refer. They must never appear upon shaded surfaces, and when it is difficult to avoid this, a blank space must be left in the shading where the letter occurs, so that it shall appear perfectly distinct and separate from the work. If the same part of an invention appear in more than one view of the drawing it must always be represented by the same character, and the same character must never be used to designate different parts.

It is suggested that numerals or letters be used without exponents.

Amendments.

RULE 73. In every amendment the exact word or words to be stricken out or inserted in the application must be specified and the precise point indicated where the erasure or insertion is to be made. All such amendments must be on sheets of paper separate from the papers previously filed, and written on but one side of the paper. Erasures, additions, insertions, or mutilations of the papers and records must not be made by the applicant.

Trade-Marks.

The publication of trade-marks under the act of February 20, 1905, in the OFFICIAL GAZETTE, commenced May 2, 1905, and will appear in each weekly number of the GAZETTE thereafter.

Extra copies of the trade-mark portion of the GAZETTE, which will be sold separately, may be obtained single or in quantities for five cents each. Coupons will be taken in payment therefor.

PATENTS

GRANTED JANUARY 23, 1906.

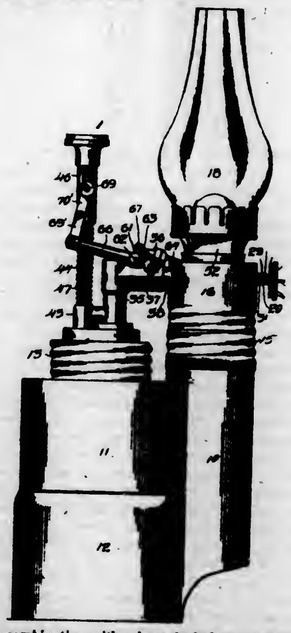
810,883. HAME. JULIUS A. ALEXANDER, Pine Bluff, Ark. Filed May 2, 1903. Serial No. 155,220.

Claim.—A hame comprising an elongated trace-fastening plate having a series of vertically-arranged openings at one side thereof to register with similar openings in the hame, and bolts for securing the plate and hame together, the opposite side edge of the plate having a series of vertically-arranged hooks provided with inturned terminals, said plate being inwardly curved at its central portion to permit of one-half of its width to extend laterally beyond the inner edge of the hame, substantially as specified.

810,884. ELECTRIC LAMPLIGHTER. PETER W. ARDUINO and ARDUINO A. ARDUINO, Stamford, Conn. Filed Apr. 22, 1904. Serial No. 204,620.

Claim.—1. The combination with a lamp, of a carrier slidably mounted adjacent to the wick-tube thereof, electrical contacts an electro-incandescent body carried by the carrier, and movable therewith to bridge the contacts and lie in igniting relation to the wick of the lamp, a battery connected with the lamp and including an element movable into and out of active relation to the cooperating element, a plunger connected with the movable element, means for holding said plunger with the attached element normally and yieldably in its inactive position, means connected with the carrier for shifting it, a pin carried by the plunger and movable therewith to engage and actuate the carrier-shifting means, and pivoted links connected between said means and the plunger and adapted to fold when the pin moves toward the shifting means and to unfold and return the shifting means when the pin moves away from the shifting means.

2. The combination with a lamp, of a carrier slidably mounted adjacent to the wick-tube thereof, electrical contacts, an electro-incandescent body carried by the carrier and movable therewith to bridge the contacts and lie in igniting relation to the wick of the lamp, a battery connected with the lamp and including an element movable into and out of active relation to the cooperating element, a plunger connected with said movable element, means for holding said plunger with the element normally and yieldably in its inactive position, and means connected between the carrier and the plunger for shifting the carrier, said plunger having initial lost motion in both directions with respect to the carrier.



3. The combination with a lamp including a font and burner-head, of a battery including a jar, igniting means carried by the lamp, means carried by the battery for actuating the igniting means, the battery comprising a jar having an upper reduced portion, of means for holding the lamp and battery with their respective mechanisms in cooperative relation, said holding means comprising a collar carried by the font and engaging the jar and a cap removably engaged with the reduced portion of the jar and impinging against the collar.

810,885. CATTLE-TAG. MARCUS J. BARTLETT, Chicago, Ill. Filed July 5, 1904. Serial No. 215,441.

Claim.—1. A cattle-tag comprising a blank of suitable form to permit of being stamped directly from a strip or sheet of metal and having its ends bent upward and oppositely dovetailed and adapted to be sprung endwise into interlocking engagement with each other to form a closed loop.

2. A cattle-tag comprising a blank of suitable shape to permit of being stamped directly from a strip or sheet of metal, and having

no ends bent upward and oppositely dovetailed and adapted to be sprung endwise into interlocking engagement with each other, said blank being scored midway between said ends to cause said ends to register in interlocking engagement when the tag is bent to form a closed loop, substantially as described

---

810,886. REPEATING TORPEDO-CANE. ROSCOE BEAN, Byron, Ohio. Filed Oct. 10, 1904. Serial No. 227,976.

Claim.—1. In an exploder of the character described, the combination, with a magazine, an explosion-chamber in communication with the magazine and a plunger operating to detonate the explosives in said chamber, of independently-movable cut-offs operating between the magazine and the explosion-chamber to feed and arrest the explosives by the action of the plunger, and means for successively actuating said cut-offs, substantially as described.

2. In an exploder of the character described, the combination, with a magazine, an explosion-chamber in communication therewith, and a plunger operating to detonate the explosives in the chamber, of cut-offs operating between the magazine and the explosion-chamber to feed and arrest the explosives, and cam-surfaces on the plunger to operate said cut-offs to feed and arrest the explosives.

3. In an exploder of the character described, the combination, with a magazine, an explosion-chamber in communication therewith, and a plunger to detonate the explosives in the chamber, of independently-movable feeding and arresting cut-offs operating between the magazine and the chamber, the normal tendency of one cut-off being to stand in cut-off position and the normal tendency of the other cut-off being to stand in non-cut-off position, and means whereby the action of the plunger successively actuates said cut-offs, substantially as described.

4. In an exploder of the character described, the combination, with a magazine, an explosion-chamber in communication therewith, and a plunger to detonate the explosives in the chamber, of independently-movable feeding and arresting cut-offs operating between the magazine and the chamber, the normal tendency of one cut-off being to stand in cut-off position and the normal tendency of the other cut-off being to stand in non-cut-off position, and cam-surfaces on the plunger to successively operate these cut-offs against their normal tendency to feed and arrest the explosives.

5. In an exploder of the character described, the combination, with a magazine, an explosion-place in communication therewith, and a plunger to detonate the explosives, of feeding and arresting cut-offs operating between the magazine and said explosion-place, the normal tendency of the one cut-off being to stand in cut-off position and the normal tendency of the other cut-off being to stand in non-cut-off position, and means to operate the cut-offs against their normal tendency alternately, and also to allow both of the cut-offs to stand in cut-off position during an intermediate interval.

6. In an exploder of the character described, the combination, with a magazine, an explosion-chamber in communication therewith, and a plunger to detonate the explosives in the chamber, of cut-offs composed of resilient wires secured to the magazine-tube and extending respectively partly across the bottom of the magazine and partly across the communication or passage between the magazine and the chamber, and having projecting contact ends, and cam-surfaces on the plunger arranged to alternately operate the cut-offs.

7. In an exploder of the character described, the combination, with a magazine, an explosion-chamber in communication therewith, and a plunger to detonate the explosives in the chamber, of cut-offs composed of spring-wires suitably secured and projecting respectively partly across the magazine and the passage or communication between it and the chamber, and cam-surfaces on the plunger arranged to alternately operate the cut-offs, and to permit both cut-offs to remain closed during an intermediate interval.

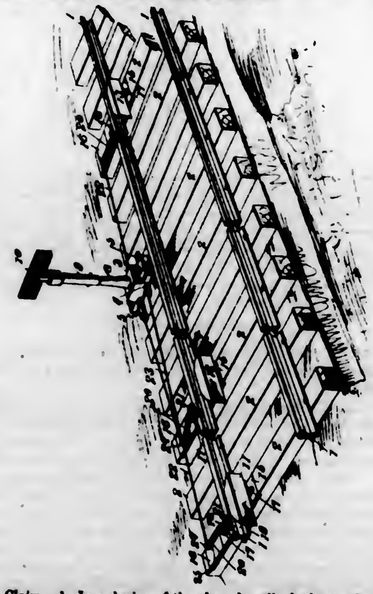
8. In an exploder of the character described, a tubular magazine-passage, having slots in the walls thereof, of independent cut-offs composed each of spring-wires extending, respectively, into said slots and within the magazine-passage in the path of the explosives, and means to operate said cut-offs.

9. In an exploder of the character described, the combination, with independent cut-offs, of a plunger having cam-surfaces adapted to operate each of said cut-offs.

10. In an exploder of the character described, the combination, with a magazine, an explosive-chamber in communication therewith, and a plunger to detonate the explosives in the chamber, of feeding and arresting cut-offs operating between the magazine and the chamber to feed and arrest the explosives, and springs for said cut-offs lying normally close to the body of the exploder, the plunger having cam-surfaces to actuate said springs to operate the cut-offs against the action of the springs, substantially as described.

11. In an exploder of the character described, the combination, with a magazine, an explosion place or chamber in communication therewith, and a plunger to detonate the explosives, of a feeding cut-off extending partly across the magazine and located and operating between the magazine and said explosion place or chamber, and including in its construction a spring adapted to move it back into position partly across the magazine, and supporting means located below said feeding cut-off and adapted to accommodate between it and the feeding cut-off an explosive, and to free such explosive when the plunger is moved from the anvil or firing-place.

810,887. RAILWAY-SIGNAL. MANASSEH W. BRAWN, Memphis, Mo. Filed Apr. 25, 1905. Serial No. 257,236.

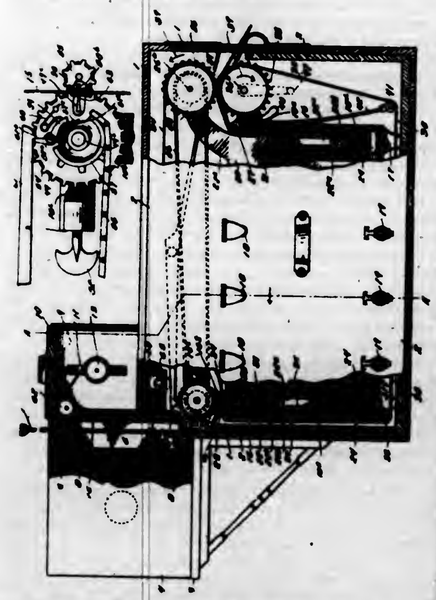


Claim.—1. In a device of the class described, the combination of a track, a casing at one side of the track, a toothed pinion mounted in said casing, a shaft connected with said pinion, a semaphore operable by said shaft spaced rack-bars having the teeth thereof in mesh with the teeth of the pinion, movable members in the length of the track upon opposite sides of the casing aforesaid to be actuated by the rolling-stock, and means connecting each of said movable members with a respective one of the rack-bars for actuation of the latter.

2. In a device of the class described, the combination of the main rails of a track, a casing at one side of the track, a toothed pinion mounted in said casing, a shaft connected with said pinion, a semaphore operable by said shaft, spaced rack-bars having the teeth thereof in mesh with the teeth of the pinion, movable rails in the length of the track upon opposite sides of the casing aforesaid, means connecting each of said movable rails with a respective one of the rack-bars for actuation of the latter, and another movable rail situated between the first-mentioned movable rails and operably connected with one of the rack-bars.

3. In a device of the class described, the combination of the main rails of a track, a casing at one side of the track, a pinion mounted in said casing, a shaft connected with said pinion, a semaphore carried by the shaft, spaced rack-bars having the teeth thereof in mesh with the teeth of the pinion and operating in the casing, the movable rails 11, 12 and 13 arranged in the length of the track for operation by the rolling-stock passing thereover, said movable rails being located adjacent main rails of the track, slides operating beneath the adjacent main rails and carrying the movable rails aforesaid, spaced plates arranged beneath said main rails and receiving the slides aforesaid therebetween, bell-crank levers operably connected with the slides at one end, the bell-crank levers connected with the rails 11 and 13 being connected with an end of opposite rack-bars in the casing, the bell-crank lever connected with the rail 12 being connected with an end of one of said rack-bars, and means for adjusting the connections between the rack-bars and the bell-crank levers.

810,888. MACHINE FOR EXPOSING AND DEVELOPING PHOTOGRAPHIC FILM. GEORGE C. BEMBLER, Oklahoma, Okla. Filed Mar. 12, 1904. Serial No. 197,846.



Claim.—1. An inclosing casing having an exposing-chamber and means for drawing sensitive film through said chamber for exposure, a tray within the casing for holding developing fluid, the tray having a series of rollers mounted across its bottom and a like series across its top, the upper rollers being supported by the tray-walls, the lower rollers being supported by a removable framework whereby they are removable from the tray between the upper rollers, a pair of aprons adapted to travel over said rollers and subject the exposed film to the action of the developing fluid, substantially as described.

2. An inclosing casing having means within it for exposing sensitive film to the light, a tray within the casing for holding developing fluid, rollers mounted across the upper part of the tray with their pintles supported by the tray-walls, a framework mounted within the tray, said framework having fingers extending down between the pintles of said rollers and supporting the pintles of the rollers at the bottom of the tray, a pair of aprons adapted to travel upon the rollers and subject the exposed film to the action of the developing fluid, substantially as described.

3. An inclosing casing having means for exposing sensitive film to the action of the light, a tray within the casing for holding developing fluid, a framework mounted within the tray, a pair of apron-driving rollers, one of said rollers being journaled in and supported by the tray and the other by the framework, a pair of aprons adapted to be driven through the developing fluid by said rollers and subject the exposed film to the action of said fluid, and an operative connection between the tray and said framework for causing said rollers to grip the aprons, substantially as described.

4. An inclosing casing having means within it for exposing sensitive film to the action of the light, a tray within said casing for holding developing fluid, a pair of rollers mounted in gripping contact with each other at each end of the tray, a framework mounted within the tray, one roller of each pair being supported by the tray and the other by the framework, a pair of aprons adapted to be driven by said rollers and subject the exposed film to the action of the developing fluid, and an elastic connection between the tray and the framework to cause said pairs of rollers to grip the aprons, substantially as described.

5. An inclosing casing having means for exposing sensitive film to the action of the light, a tray within said casing for containing developing fluid, a pair of apron-driving rollers mounted at each end of the tray, a series of apron-supporting rollers journaled across the top of the tray with their end pintles supported by the tray-walls, a second series of apron-supporting rollers journaled across the bottom of the tray, a framework mounted within the tray and having fingers extending down between the pintles of the first-named series of rollers, the lower ends of said fingers supporting the pintles of said second series of apron-supporting rollers, one roller of each said pair of apron-driving rollers being supported by the tray and the other by the framework, a pair of gripping-aprons adapted to be driven in contact with each other by said driving-rollers over the said supporting-rollers for subjecting the exposed film to the developing fluid, and an elastic connection between the tray and the framework for causing the apron-driving rollers to grip the aprons, substantially as described.

6. In a photographic and developing apparatus having a receptacle for the developer, flexible aprons movable into the receptacle, said aprons being provided with transverse rows of perforations.

7. In a photographic and developing apparatus having a receptacle for the developer, a pair of perforated flexible endless aprons movable into the receptacle, and adapted to contact the opposite surfaces of a film, substantially as described.

8. In a photographic and developing apparatus, flexible perforated belts adapted to carry the exposed film through the developing fluid in one direction, substantially as described.

9. An inclosing casing, means within the casing for holding a supply of sensitive film, a chamber in which to make the proper exposure of the film to the light, a pair of gripping-rollers adapted to draw the film through the exposing-chamber and having mechanism associated with them for severing the film at regular intervals after it is drawn through the chamber, a tray within the casing for containing developing fluid, a pair of gripping-aprons arranged to receive the severed portions of film from the gripping-rollers and carry them through the developing fluid in the tray, means for driving the gripping-rollers and the aprons, and means for stopping the movement of said rollers while each severed portion of film is drawn into the developing fluid by the aprons, substantially as described.

10. An inclosing casing adapted to contain a supply of sensitive film and having a chamber for making the proper exposure of said film to the light, a pair of gripping-rollers adapted to draw the film through the exposing-chamber and sever said film at regular intervals, a tray within the casing for containing developing fluid, a pair of endless aprons arranged to circulate through the developing fluid in the tray and carry the severed portions of film, mechanism for driving the gripping-rollers and the aprons, and means for permanently stopping the action of said rollers while the aprons continue in action, substantially as described.

11. A casing adapted to hold a supply of sensitive film and having means for properly exposing said film to the light, a drawer arranged to slide into the casing, a tray mounted within the drawer for holding developing fluid, and mechanism for subjecting the exposed film to the action of the fluid in the tray, said mechanism being supported by the drawer and being removable from the casing therewith, substantially as described.

12. A casing adapted to hold a supply of sensitive film and having means for making the proper exposure of said film to the light, a drawer arranged to slide into the casing, a tray mounted within the drawer for containing developing fluid, a pair of aprons mounted within the tray for carrying the exposed film through the developing fluid, a pair of rollers adapted to drive the aprons through the developing fluid, an end pintle of one of the rollers extending through the drawer-front and having a crank for driving it, substantially as described.

13. A casing having means for exposing sensitive film, a tray within the casing for holding developing fluid, means for subjecting the exposed film to the action of the developing fluid, the casing having the proper filling-funnels and emptying-cocks mounted permanently on the outside of one of its walls for said tray, said funnels and cocks having permanent communication with said tray through said wall, substantially as described.

14. An inclosing casing having an exposing-chamber and means for drawing film through said chamber within the casing, a receptacle within the casing for holding developing fluid, and a pair of perforated aprons adapted to grip the film within the casing and carry said film through the receptacle.

15. A casing attachable to a camera and having mechanism for exposing a sensitive film to the action of said camera, a drawer arranged to slide within and form a part of the casing, a tray mounted within the drawer for containing developing fluid, a pair of endless aprons mounted upon driving-rollers and arranged to carry the exposed film through the developing fluid, a shaft or pintle of one of the driving-rollers extending through a wall of the casing and having a crank for driving the aprons, and a pair of gripping-rollers adapted to feed the exposed film into engagement with the aprons, substantially as described.

16. A casing adapted to hold a supply of film and having a chamber in which to make the proper exposure of said film to the light, said chamber being attachable to a camera, a pair of gripping-rollers adapted to draw the film through said chamber, one of said rollers having a blade projecting from its face for severing the film at regular intervals, a tray within the casing for containing developing fluid, and a pair of gripping-aprons adapted to receive the severed portions of film from said gripping-rollers and carry them through the developing fluid, substantially as described.

17. A casing having within it a chamber adapted to hold a spool of sensitive film, an exposing-chamber for making the exposure of said film to the light, said exposing-chamber being attachable to a camera, a tray within the casing for containing developing fluid, said tray being mounted within a drawer portion removable from the casing, a pair of film-gripping rollers mounted over one end of the tray in lugs extending upward from said tray, a framework mounted within the tray, a pair of apron-gripping rollers mounted at each end of the tray, one roller of each pair being supported by the tray and the other by the framework, a pair of aprons adapted to be driven in gripping contact with each other by said apron-gripping rollers through the developing fluid, said aprons being arranged to receive the film from the film-gripping rollers and carry it through the developing fluid, substantially as described.

18. In a photographic and developing apparatus having a receptacle for the developer, flexible aprons movable in the receptacle, said aprons having transverse rows of perforations quincunxially arranged.

19. An inclosing casing having an exposing-chamber and means for drawing film through said chamber within the casing, a receptacle within the casing for holding fluid, and a pair of perforated aprons adapted to carry the film between them and within the casing through the receptacle and eject it from the casing.

20. A casing having an exposure-chamber to which a camera may be attached, a drawer working within the casing, a developer apparatus carried by the drawer, and means for securing the developer apparatus to the drawer, said means comprising a part of the developer apparatus.

21. An inclosing casing adapted to contain a supply of film and having a chamber for making the proper exposure of said film to the light, a pair of gripping-rollers adapted to draw the film through the exposing-chamber and cover said film at intervals, one of said rollers being movable with relation to the other, a receptacle within the casing for containing developing fluid, aprons arranged to pass through the fluid within the receptacle and carry the severed portions of the film, and means for driving the gripping-rollers and aprons.

22. An inclosing casing adapted to contain a supply of film and having a chamber for making the proper exposure of said film to the light, a receptacle within the casing for containing developing fluid, said receptacle having lugs provided with eyes and slots, a roller mounted in the eyes, a second roller mounted in the slots, means for forcing the rollers in the slots into contact with the other roller, said rollers being adapted to draw the film through the exposure-chamber, means carried by the rollers for severing the film at intervals, aprons arranged to pass through the fluid in the receptacle and carry the severed portions of the film, and mechanism for driving the rollers and the aprons.

23. An inclosing casing adapted to contain a supply of film and having a chamber for making the proper exposure of said film to the light, a receptacle within the casing for containing developing fluid, said receptacle having lugs provided with eyes and slots, a roller mounted in the eyes, a second roller mounted in the slots, blocks sliding in the slots and bearing against the roller, means for imparting movement to the blocks, said rollers being adapted to draw the film through the exposure-chamber and to sever the film at intervals, aprons arranged to pass through the fluid within the receptacle and to carry the severed portions of the film, and means for operating the rollers and the aprons.

24. An inclosing casing adapted to contain a supply of film and having a chamber for making the proper exposure of said film to the light, a receptacle within the casing for containing a developing fluid, said receptacle having lugs provided with eyes and slots, a roller mounted in the eyes, a second roller mounted in the slots, blocks sliding in the slots and bearing against the roller, a screw for operating said blocks, said rollers being adapted to draw the film through the exposure-chamber and to sever the film at intervals, aprons arranged to pass through the fluid within the receptacle and to carry the severed portions of the film, and means for operating the rollers and aprons.

25. An inclosing casing adapted to contain a supply of film and having an exposure-chamber for making the proper exposure of said film to the light, a pair of gripping-rollers adapted to draw the film through the exposure-chamber and sever the said film at intervals, a receptacle within the casing for containing a developing fluid, aprons arranged to pass through the fluid within the receptacle and to carry the severed portions of the film, and means for driving the rollers and the aprons.

26. An inclosing casing adapted to contain a supply of film and having an exposure-chamber for making the proper exposure of the film to the light, a pair of gripping-rollers adapted to draw the film through the exposing-chamber, a cutting-blade carried by one of the rollers for severing the film at intervals, a receptacle within the casing for containing developer fluid, aprons arranged to pass through the fluid in the receptacle and carry the severed portions of the film, and means for driving the gripping-rollers and the aprons.

27. An inclosing casing adapted to contain a supply of film and having a chamber for making the proper exposure of the film to the light, means within the casing for drawing the film through the exposure-chamber and severing the film at intervals, a receptacle within the casing for containing developing fluid, and means for carrying the severed portions of the film through said fluid.

28. An inclosing casing adapted to contain a supply of film and having an exposure-chamber for the proper exposure of the film to the light, gripping-rollers for drawing said film through the exposure-chamber, a cutting-blade carried by one of the rollers for severing the film at intervals, a receptacle within the casing for containing developing fluid, and means for carrying the severed portions of the film through the fluid.

29. An inclosing casing adapted to contain a supply of film and having a chamber for making the proper exposure of the film to the light, gripping-rollers for drawing said film through the exposure-chamber, a cutting-blade carried by one of the rollers for severing the film at intervals, said blade having its cutting edge toothed, a receptacle within the casing for containing developing fluid, and mean for carrying the severed portions of the film through the fluid.

30. An inclosing casing adapted to contain a supply of film and having a chamber for making the proper exposure of the film to the light, gripping-rollers for drawing said film through the exposure-chamber, one of said rollers being provided with a groove, a cutter-blade carried by the other roller adapted to extend within the groove and sever the film at intervals, a receptacle within the casing for containing developing fluid, and means for carrying the severed portions of the film through the fluid.

31. An inclosing casing adapted to contain a supply of film and having a chamber for properly exposing the film to the light, gripping-rollers for drawing said film through the chamber and to sever said film at intervals, aprons for carrying the severed portions of the film, a receptacle within the casing for containing developer fluid, said aprons being adapted to pass through said fluid, means for operating the aprons, and connections between the apron-operating means and the gripping-rollers for operating said rollers.

32. An inclosing chamber adapted to contain a supply of film and having an exposing-chamber for properly exposing said film to the light, gripping-rollers operatively connected one to the other for drawing said film through the exposing-chamber and to sever the film at intervals, a receptacle for holding developer fluid within the casing, and means for carrying the severed portions of the film through the fluid.

33. An inclosing casing adapted to contain a supply of film and having an exposing-chamber for making the proper exposure of said film to the light, gripping-rollers for drawing the film through the exposure-chamber, a toothed wheel carried by each roller meshing one with the other, a receptacle in the casing for holding the developer fluid, and means for carrying the film through the fluid.

34. An inclosing casing adapted to contain a supply of film and having a chamber for exposing said film to the light, gripping-rollers operatively connected one to the other for drawing said film through the exposure-chamber, said gripping-rollers also holding the film within the chamber taut, a receptacle within the casing for containing developer fluid, and means for carrying the severed portions of the film through the fluid.

35. An inclosing casing adapted to contain a supply of film and having an exposure-chamber for making a proper exposure of the film to the light, gripping-rollers for drawing said film through the exposure-chamber and to sever the film at intervals, a fluid-holder within the casing, aprons for carrying the severed portions of the film through the fluid contained within the holder, means for operating the aprons and means whereby the apron-operating means drives the gripping-rollers.

36. An inclosing casing adapted to contain a film and having a chamber for exposing said film to the light, gripping-rollers for drawing said film through the chamber and to sever the film at intervals, a fluid-holder within the casing, aprons for carrying the severed portions of the film through the fluid contained within the holder, driving-wheels for the aprons, and a connection between the driving-wheels and the gripping-rollers for operating said rollers.

37. An inclosing casing adapted to contain a film and having a chamber for exposing said film to the light, gripping-rollers for drawing said film through the chamber and to sever the film at intervals, a fluid-holder within the casing, aprons for carrying the severed portions of the film through the fluid contained within the holder, driving-wheels for the aprons, a connection between the driving-wheels and the gripping-rollers for operating said rollers, mechanism for operating the drive-wheels, and means for preventing movement of the drive-wheels in but one direction.

38. An inclosing casing adapted to contain a film and having a chamber for exposing said film to the light, gripping-rollers for drawing the film through the chamber and to sever the film at intervals, a fluid-holder in the casing, aprons for carrying the severed portions of the film through the fluid contained within the holder, driving-wheels for the aprons, a connection between the driving-wheels and gripping-rollers for operating said rollers, means for operating the drive-wheels, and means carried by the fluid-holder for preventing movement of the drive-wheels in but one direction.

39. An inclosing casing adapted to contain a supply of film and having a chamber for making proper exposure of the film to the light, gripping-rollers for drawing said film through the chamber and to cover the film at intervals, a fluid-holder arranged within the casing, aprons for carrying the severed portions of the film through the fluid contained within the holder, driving-wheels for the aprons, meshing gear-wheels carried by the drive-wheels, a detent secured to the holder and engaging the teeth of one of the gear-wheels for holding said wheels against movement in but one direction, a connection between the driving-wheels and gripping-rollers for operating said rollers, and means for operating the drive-wheels.

40. An inclosing casing adapted to contain a supply of film and having a chamber for making proper exposure of the film to the light, gripping-rollers for drawing said film through the chamber and to sever the film at intervals, a sprocket-wheel mounted loosely with relation to one of the rollers, means for causing the roller to travel with said sprocket-wheel, a fluid-holder within the casing, aprons for carrying the severed portions of the film through the fluid contained within the holder, drive-wheels for the aprons, a connection between the driving-wheels and the sprocket-wheel for operating the same, and means for operating the drive-wheels.

41. An inclosing casing having a supply of film therein and a chamber for exposing the film to the light, gripping-rollers for drawing said film through the chamber and to sever the film at intervals, a sprocket-wheel mounted loosely with relation to one of the rollers, a toothed extension formed on the sprocket-wheel, a detent carried by the roller for normally engaging the teeth of the extension, aprons for carrying the severed portions of the film, a fluid-holder within the casing, said aprons passing therethrough, drive-wheels for the aprons, and a connection between the drive-wheels and the sprocket-wheel for operating said sprocket.

42. An inclosing casing having a supply of film therein and a chamber for making a proper exposure of the film to the light, gripping-rollers for drawing said film through the chamber and to sever the film at intervals, a sprocket-wheel mounted loosely with relation to one of the rollers, a toothed extension on the sprocket-wheel, a detent carried by the roller normally engaging the toothed extension, a fluid-holder within the casing, aprons arranged to carry the severed portions of the film through the fluid contained within the holder, drive-wheels for the aprons, a connection between the drive-wheels and the sprocket-wheel for operating said sprocket-wheel, and means controlled by the drive-wheels for disengaging the detent from the toothed extension.

43. An inclosing casing adapted to contain a film and having a chamber for exposing said film to the light, gripping-rollers for drawing said film through the casing and to sever the film at intervals, a sprocket-wheel mounted loosely with relation to one of the rollers, a detent carried by the roller, an extension carried by the sprocket-wheel normally engaged by the detent, a lever pivoted within the casing adapted to disengage the detent from the extension, a fluid-holder within the casing, aprons for carrying the severed portions of the film through the fluid contained within the holder, a connection between the sprocket-wheel and driving-wheels for operating the rollers, and means for operating the wheels.

44. An inclosing casing adapted to contain a film and having a chamber for exposing said film, gripping-rollers for drawing the film through the casing and to sever the film at intervals, a sprocket-wheel mounted loosely with relation to one of the rollers, a detent carried by the roller normally engaging the sprocket-wheel to cause the same to rotate therewith, a lever pivoted within the casing adapted to disengage the said detent from the sprocket, a fluid-holder within the casing, aprons for carrying the severed portions of the film through the fluid contained within the holder, a connection between the sprocket-wheel and driving-wheels for operating the rollers, and means for operating the wheels.

45. An inclosing casing adapted to contain film and having a chamber for exposing said film, gripping-rollers adapted to draw the film through the casing and to sever the film at intervals, a sprocket-wheel mounted loosely with relation to one of the rollers, a detent carried by the roller normally engaging the sprocket-wheel to cause the same t rotate with the roller, a lever pivoted within the casing adapted to disengage said detent from the sprocket-wheel, a fluid-holder within the casing, aprons for carrying the severed portions of the film through the fluid contained within the holder, a connection between the driving-wheels and the sprocket-wheel for operating the same, means carried by one of the driving-wheels for causing the lever to disengage the detent from the sprocket-wheel, and means for operating the wheels.

46. An inclosing casing adapted to contain film and having a chamber for exposing said film, gripping-rollers adapted to draw the film through the chamber and to sever the film at intervals, a sprocket-wheel mounted loosely with relation to one of the rollers, a detent carried by the roller adapted to engage the sprocket-wheel to rotate therewith, a lever pivoted intermediate its length, one end of said lever being adapted to contact with the detent and disengage it from the sprocket-wheel, a fluid-holder within the casing, aprons for carrying the several portions of the film through the fluid contained within the holder, driving-wheels for the aprons, a connection between the driving-wheels, a pin carried by one of the driving-wheels for contacting with one end of the lever to force the opposite end out of contact with the detent, and means for operating the driving-wheels.

47. An inclosing casing having an exposing-chamber, means for drawing film through said chamber for exposing and severing the same, a receptacle within the casing for holding developing fluid, means for carrying the severed portions of film through the receptacle, said drawing means and carrying means being operatively connected and means whereby the drawing means is held positively inoperative independent of the carrying means.

48. An inclosing casing having an exposing-chamber, means for drawing film through said chamber for exposing and severing the same, a receptacle within the casing for holding the developing fluid, means for carrying the severed portions of film through the re-

ceptacle, said drawing means and carrying means being operatively connected, and a cam adapted to hold the drawing means inoperative independent of the carrying means.

49. An inclosing casing having an exposure-chamber, means for drawing film through said chamber for exposing and severing the same, a receptacle within the casing for holding developing fluid, means for carrying the severed portions of film through the receptacle, said drawing means and carrying means being operatively connected, and a cam operated from the exterior of the casing adapted to hold the drawing means inoperative independent of the carrying means.

50. An inclosing casing having means for exposing film, a receptacle within the casing for holding developing fluid, means for drawing the film, severing the same, and carrying the severed portions through the fluid in the receptacle, means for operating the same, and a stop for the operating means to indicate when a portion of the film has been severed and submerged within the fluid.

51. An inclosing casing having an exposing-chamber and a delivery-opening, means for drawing film through the chamber within the casing, a receptacle within the casing adapted to contain fluid, and a pair of perforated aprons adapted to grip and carry the film within the casing through the receptacle and to eject said film through the discharge-opening.

52. An inclosing casing having an exposing-chamber, means within the casing for drawing film through the exposing-chamber within the casing, a receptacle adapted to contain fluid within the chamber, means for carrying the film through the receptacle, and means arranged beneath the drawing means for guiding the severed portions to the conveyer means.

53. A casing having an exposing-chamber adapted to contain film, means for drawing said film within the casing and severing the same, a drawer fitting within the casing, a receptacle on said drawer adapted to contain fluid, means for carrying the severed films through the receptacle, and means secured to an edge of the drawer for guiding the severed films to the conveyer means.

54. An inclosing casing having an exposing-chamber adapted to contain film, means for drawing film within the casing and severing the same, developing apparatus within the casing, means for carrying the films through said developing apparatus, and a stationary apron to guide the films to said carrying means.

55. An inclosing casing having an exposing-chamber, adapted to contain film, means for drawing the film within the casing and severing the same, developing apparatus within the casing, means for carrying the films through said developing apparatus, and a depending stationary apron to guide the films to said carrying means.

56. A casing having an exposing-chamber adapted to contain film, means for drawing said film within the casing and severing the same, a drawer fitting within the casing, a receptacle on said drawer, adapted to contain fluid means for carrying the severed films through the receptacle, and a downwardly-curved stationary apron secured to an edge of the drawer to guide the films to the carrying means.

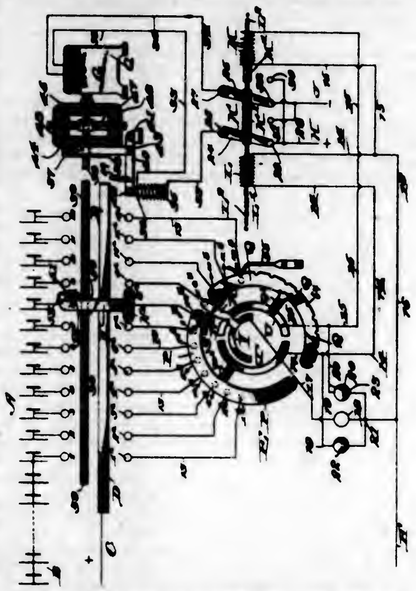
57. An inclosing casing having means for exposing film, a receptacle within the casing for holding developing fluid, means for drawing the film, severing the same, and carrying the severed portions through the receptacle, means for operating the drawing means, and a stop acting in conjunction with the operating means to indicate when a portion of the film has been severed and submerged in the fluid.

58. An inclosing casing having an exposing-chamber, means for drawing the film through said chamber and severing the same, a receptacle within the casing for holding developing fluid, means for carrying the severed films through the receptacle, said drawing means and carrying means being operatively connected, a spindle mounted within the casing, a cam fixed on the spindle adapted to hold the drawing means inoperative, independent of the carrying means, and means for operating the spindle.

59. An inclosing casing having an exposing-chamber, means for drawing film through said chamber, and severing the same, a receptacle within the casing for holding developing fluid, means for carrying the severed films through the receptacle, said drawing means and carrying means being operatively connected, an arm depending from the top of the casing, a spindle mounted in said arm, and a side of the casing, a cam on the spindle adapted to hold the drawing means inoperative, independent of the carrying means, and means for operating the spindle.

60. In a photographic and developing apparatus having a receptacle for the developer, a pair of perforated aprons movable into the receptacle and adapted to contact the opposite surfaces of the film.

810,389. END-CELL SWITCH. JOSEPH BIVEN, New York, N. Y., assignor to General Storage Battery Company, New York, N. Y., a Corporation of New York. Filed Oct. 14, 1904. Serial No. 228,605.



Claim.—1. An electrical switching apparatus, comprising devices to be controlled, a main contact-arm controlling the same and adapted to move in either direction, reversible actuating means for said arm, a reversing-switch, a controller connected to control said switch, and electric circuits and connections whereby movement of the controller to a given position causes movement of the main contact-arm in the desired direction to a predetermined position.

2. An electrical switching apparatus, comprising devices to be controlled and switched into and out of circuit, series of main and auxiliary contacts, a main contact-arm connected in circuit and arranged to make contact with said contacts, means for actuating said arm in either direction, and a controller adapted to be situated at a distance from the devices to be controlled and connected to control said actuating means, with circuits and connections so arranged that the direction of movement and position of the main contact-arm may be determined from a distance.

3. The combination with the end cells of a storage battery, of a main contact-arm for controlling the number of cells in circuit, means for actuating said arm in either direction, a controller adapted to be situated at a distance and connected to control the said actuating means, with circuits and connections so arranged that the main contact-arm is automatically moved and brought to rest by moving the controller into a given position.

4. An electrical switching apparatus, comprising devices to be controlled, provided with a series of main contacts, an auxiliary series of contacts corresponding thereto, a main contact-arm connected in circuit and adapted to be moved over said main and auxiliary contacts, a controller having a series of controller-contacts corresponding to the main and auxiliary contacts and connected to the auxiliary contacts, means for actuating said main contact-arm backward and forward, and operative means for controlling said actuating means from the controller, whereby movement of the controller to a given position causes the movement of the main contact-arm in the desired direction to a predetermined position.

5. The combination with the end cells of a storage battery, of a switch for controlling the number of cells in circuit, means for actuating said switch automatically from a distance, and means for indicating to the operator by the position of the controller the direction and extent of movement of the switch.

6. The combination with the end cells of a storage battery, of a switch for controlling the number of cells in circuit, reversible driving means for actuating said switch automatically from a distance, and means for permitting said actuating means to operate in either direction after the said switch has reached its predetermined position and come to rest.

7. The combination with the end cells of a storage battery, of a switch for controlling the number of cells in circuit, a hand-controller, and circuits an apparatus controlled thereby for automatically moving said switch to any position in its entire range of travel by moving the hand-controller to a corresponding position, and means for preventing said switch from stopping before reaching its desired position.

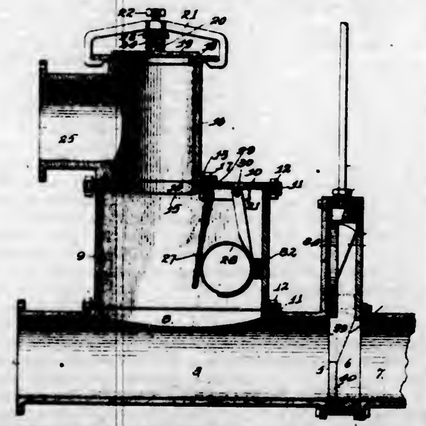
8. The combination with the end cells of a storage battery, of a switch for the same, means for actuating said switch having rotating members, electrical means for interfering with the rotation of one of said members and thereby actuating the switch, and means for automatically releasing the said member when the switch reaches its desired predetermined position.

9. The combination with the end cells of a storage battery, of a switch for the same, means for actuating said switch having rotating members, an electromagnet operatively arranged to interfere with the rotation of one of said members and thereby actuate the switch, and circuits and apparatus for automatically moving said switch to a given position.

10. In an end-cell switch, the combination with the contact, of a brush coöperating therewith both the body portion and contact edges being arranged diagonally to the line of travel, to distribute wear on the contact.

11. In an end-cell switch, the combination with the contact, of a brush coöperating therewith, comprising a plurality of metallic sheets or leaves, both the body portion and contact edges being arranged diagonally to the line of travel, whereby wear on the contact is distributed.

810,390. BACK-PRESSURE TRAP FOR SEWER-PIPES. PETER J. ROSE, St. Louis, Mo. Filed Aug. 16, 1904. Serial No. 220,705.

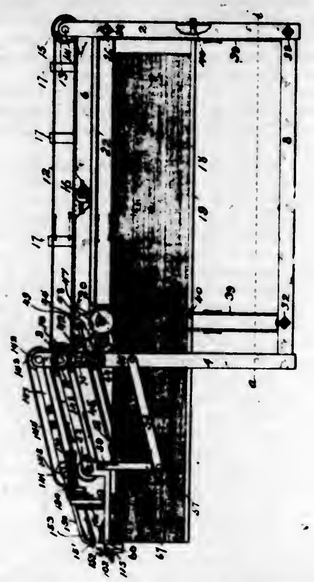


Claim.—A device of the class described comprising a rectangular casing, a pipe having a rectangular flange supporting said casing, a cover provided with an opening located upon said rectangular casing, a valve-seat located within said opening, a T-casing located upon said cover and in alinement with the valve-seat, a pair of angles suspended to the under side of said cover immediately to the rear of the valve-seat, a valve hingedly suspended from said angles, an elongated float, a pair of arms supporting said float and hingedly suspended to the angles, said float arranged to come in contact with the under side of the valve to automatically close said valve by the flow of water from the sewer, substantially as specified.

810,391. PAPER-FEEDING MACHINE. HARRY BRADSHAW, Kansas City, Mo., assignor of one-half to Warren D. House, Kansas City, Mo. Filed July 18, 1904. Serial No. 217,114.

Claim.—1. In a paper-feeder, the combination with a sheet-carrying device provided with two members for gripping between them and removing from the pile one or more sheets thereof, of means for removing all sheets but one from between said gripping members and permitting said removed sheets to fall back on the pile.

2. In a paper-feeder, the combination with a sheet-carrying device having two members provided with means for gripping between them and reversing the position of a part of each of one or more of the top sheets of a pile of paper, of means for withdrawing from between said two members and permitting to fall back on the pile all but one of said reversed sheets.



3. In a paper-feeder, the combination with a sheet-carrying device having two members provided with means for gripping between them and reversing the position of a part of each of one or more of the top sheets of a pile of paper, of means for withdrawing from between said two members and permitting to fall back on the pile all but one of said reversed sheets, and means for seizing and stripping from the pile said reversed sheet retained gripped by the two members.

4. In a paper-feeder, the combination with a sheet-carrying device comprising two sheet-gripping devices between which one or more sheets of paper are gripped, of a rubbing device, and means by which said rubbing device may apply a rubbing pressure to the sheets against one of the gripping devices.

5. In a paper-feeder, the combination with two sheet-gripping devices adapted to grip between them one or more sheets of a pile, of a rotary rubbing device, and means by which said rubbing device may exert a pressure upon the sheets against the surface of one gripping device.

6. In a paper-feeder, the combination with two sheet-gripping devices adapted to grip between them one or more sheets of paper, one device having a surface of a relatively greater frictional nature and the other a surface of a relatively less frictional nature, of a rubbing device adapted to be rubbed against the sheets upon the gripping device having the greater frictional nature.

7. In a paper-feeder, the combination with two sheet-gripping devices one having a surface of a relatively greater frictional nature and the other a surface of a relatively less frictional nature exposed to the sheets gripped between them, of a rotary rubbing device adapted to press upon the sheets against the gripping device having the greater frictional nature.

8. In a paper-feeder, the combination with two sheet-gripping devices, each having a frictional surface exposed to the sheets gripped between them, of means for rotating one of said two devices, and a third device for pressing the sheets against the other of said two devices, the third device having a surface possessing frictional qualities relatively less than either of the other two.

9. In a paper-feeder, the combination with a sheet-gripping device, of a resilient device adapted to bear thereupon, means for inserting one or more sheets between said devices, and a rubbing device for bearing upon the sheets against the gripping device.

10. In a paper-feeder, the combination with a gripping device having a frictional surface, a resilient device for pressing one or more sheets upon said frictional surface, and a rubbing device having a frictional surface for rubbing against said sheets against the frictional surface of the gripping device.

11. In a paper-feeder, the combination with a gripping device having a frictional surface, of a resilient gripping device having a surface of a relatively less frictional nature for pressing the sheets against the frictional surface of the other gripping device, and a frictional rubbing device for rubbing against said sheets against the gripping device having the greater frictional nature.

12. In a paper-feeder, the combination with a frictional gripping device, of a resilient device bearing thereupon, and a rotary rubbing device provided with means for bearing against the frictional gripping device.

13. In a paper-feeder, the combination with means for raising one or more sheets from a pile of paper, of two gripping devices for seizing said raised sheets, one of said gripping devices having a surface of a frictional nature and the other a surface of a relatively less frictional nature exposed to the sheets of paper, and a rubbing device for rubbing against said sheets and against the gripping device having the greater frictional nature.

14. In a paper-feeder, the combination with two gripping devices simultaneously movable with each other and movable toward and from each other, of a rotary rubbing device movable simultaneously with said gripping devices and movable toward and from and adapted to bear upon one of said gripping devices.

15. In a paper-feeder, the combination with a frictional rubbing device movable along the top of a pile of paper for raising therefrom parts of one or more sheets of the pile, a lifting device for supporting and lifting the sheets detached by the said rubbing device, two sheet-gripping devices for gripping between them the said lifted sheets, and a rubbing device for bearing against one of said gripping devices and upon the sheet or sheets held thereon by the other gripping device.

16. In a paper-feeder, the combination with means for partly raising from the pile one or more sheets of paper, of two gripping devices for seizing between them said raised portions of said sheets, and a rubbing device for bearing against one of said gripping devices and upon the sheets held thereon.

17. In a paper-feeder, the combination with means for partly raising from the pile one or more sheets of paper, of two gripping devices for seizing between them said raised portions of said sheet, one of said gripping devices being provided with a frictional surface exposed to the sheets, and a frictional rubbing device adapted to be pressed upon the sheets against the frictional surface of the gripping device.

18. In a paper-feeder, the combination with means for raising portions of one or more sheets from a pile of paper, of two gripping devices for seizing between them the raised sheets, one gripping device having a frictional surface, the other gripping device being resilient and holding the sheets upon the said frictional surface, and a rotary frictional device for rubbing against the sheets upon said frictional surface.

19. In a paper-feeder, the combination with means for raising portions of one or more sheets from a pile of paper, of a gripping device for seizing said raised sheets, means for moving said gripping device so as to reverse relative to the pile the gripped portions of the sheets, means for removing from the gripping device all the sheets except the top sheet of the pile, and means for taking the top sheet from said gripping device and stripping it from the pile of paper in the said reversed position.

20. In a paper-feeder, the combination with a sheet-carrying device provided with two sheet-gripping devices movable toward and from each other, of means for rotating said carrying device, a rubbing device carried by said carrier and adapted to bear upon one of the gripping devices, means for rotating said rubbing device, means for raising one or more sheets and depositing them between said gripping devices, and means for seizing the sheets carried by the gripping devices and stripping them from the pile.

21. In a paper-feeder, the combination with a friction-pad, of means for holding the top sheet or sheets against said pad, and a rotary device having a frictional surface movable toward and from and adapted to bear against said pad.

22. In a paper-feeder, the combination with a friction-pad, of resilient means for holding the top sheet or sheets against said pad, and a rotary device having a frictional surface movable toward and from and adapted to bear against said pad.

23. In a paper-feeder, the combination with a friction-pad, of a spring for holding the top sheet or sheets against said pad, and a rotary device having a frictional surface movable toward and from and adapted to bear against said pad.

24. In a paper-feeder, the combination with a friction-pad, of a rotary shaft provided with a crank-arm supporting said pad, means for rotating said shaft around its axis, means for revolving said shaft around an axis disposed at right angles to the axis of rotation, a spring carried by said crank-arm and adapted to press the top sheet or sheets of paper against said pad, a friction-disk rotatively mounted on said crank-arm, the pad and disk being movable relatively toward and from each other, and means for rotating said disk.

25. In a paper-feeder, the combination with means for raising one or more top sheets of paper from a pile, of a friction-pad, a frictional rotary device, means for rotating said rotary device, means for moving said rotary device and said pad relatively toward and from each other, and a device for pressing said raised sheets against said pad.

26. In a paper-feeder, the combination with means for raising one or more sheets from the pile, of a friction-pad, a spring for holding said raised sheets against said pad, a friction-disk, means for rotating said friction-disk, and means for moving relatively the said pad and disk toward and from each other.

27. In a paper-feeder, the combination with means for raising a part of one or more sheets from the pile, of two friction devices adapted to grip between them the raised sheet or sheets, means for rotating one of said friction devices, means for holding the raised sheets against the other of said friction devices, means for revolving said friction devices around each other, and means for revolving said friction devices around an axis disposed at an angle to the axis of revolution around each other.

28. In a paper-feeder, the combination with means for raising one or more of the top sheets of the pile, of two friction devices adapted to grip between them said sheet or sheets, means for rotating one of said friction devices, means moving relatively said devices toward and from each other, and means for so moving said friction devices as to reverse the position of the sheet or sheets held between them.

29. In a paper-feeder, the combination with means for raising one or more sheets from the pile, of two friction devices adapted to grip between them said sheets, means for rotating one of said devices, means for pressing said sheets against the other of said friction devices, means for relatively moving said friction devices toward and from each other, and means for so moving said friction devices as to reverse the position of the sheet or sheets held between them.

30. In a paper-feeder, the combination with means for raising one or more sheets from the pile, of two friction devices adapted to grip between them said sheets, means for rotating one of said devices, resilient means for pressing said sheets against the other of said friction devices, means for relatively moving said friction devices toward and from each other, means for so moving said friction devices as to reverse the position of the top sheet retained between them, and means for seizing said reversed sheet from said friction devices and stripping it from the pile.

31. In a paper-feeder, the combination with means for raising a part of one or more sheets from the pile, of means for gripping said raised portions of the sheets and carrying them toward a sheet-stripping mechanism, means for removing from said gripping means and throwing back on the pile all but the top one of said raised sheets, and a stripping mechanism for seizing and stripping from the pile said top sheet.

32. In a paper-feeder, the combination with means for raising a part of one or more sheets from a pile, of means for gripping said raised portions of the sheets and carrying them toward a stripping mechanism, means for removing from said gripping means all but the top sheet of said raised sheets and throwing said removed sheets back upon the pile, means for so moving the said gripping means as to reverse the position of the said top sheet, and a stripping mechanism for seizing and stripping from the pile said top sheet.

33. In a paper-feeder, the combination with means for raising a part of one or more sheets from the pile, of a frictional pad, means for pressing said raised sheets against said pad, a rubbing device, means for applying said rubbing device with a rubbing pressure against the sheets held pressed against said pad, means for so moving said pad and sheet-pressing means as to reverse the position of the sheets held thereby, and a sheet-stripping mechanism for seizing and stripping from the pile the sheet retained by the said pad and sheet-pressing means.

34. In a paper-feeder, the combination with means for raising a part of one or more sheets from a pile, of a frictional pad, adapted to receive thereon the raised parts of said sheets, a spring for holding said sheets against said pad, a frictional disk, means for rotating said friction-disk, means for relatively moving said disk and said pad toward and from each other, a sheet-stripping means, and means for moving the pad, spring and disk between the sheet-raising and sheet-stripping means.

35. In a paper-feeder, the combination with means for raising a part of one or more sheets from the pile, of a frictional pad adapted to receive thereon the raised sheets, a spring for holding the sheets against the pad, a rotary disk for rubbing against the sheets and against the pad, means for rotating said disk, means for relatively moving the pad and disk toward and from each other, a sheet-stripping mechanism, and means for so moving said pad, spring and disk as to reverse the position of the sheet retained thereby and carry it toward the sheet-stripping mechanism.

36. In a paper-feeder, the combination with a supporting-frame, of a table for carrying the pile of paper vertically movable on the frame, a swinging frame pivotally connected with the supporting-frame having two supporting-shoes and adapted to alternately rest upon the pile of paper carried by the table, a sheet separating and detaching mechanism supported by the swinging frame for withdrawing the sheets from the pile, and means controlled by the movement of the swinging frame for elevating the table.

37. In a paper-feeder, the combination with a supporting-frame, of a table for carrying the pile of paper and vertically movable upon the frame, a sheet-separating and a sheet-stripping mechanism supported by a swinging frame, the said swinging frame pivotally connected with the supporting-frame and having two supporting-shoes and adapted to alternately rest upon the pile of paper, means for supporting and elevating the table upon the supporting-frame, means for actuating said table-elevating means, and means controlled by the swinging of the swinging frame for controlling the table-elevating means.

38. In a paper-feeder, the combination with a supporting-frame, of a table vertically movable thereon, a sheet carrying and supporting mechanism carried by said frame, a swinging frame pivotally connected with the table and having two supporting-shoes adapted to alternately rest upon the pile of paper, a sheet-separating mechanism supported on the swinging frame, a sheet-stripping mechanism for seizing the separated sheets from the sheet-separating mechanism and delivering them to the sheet-registering mechanism, means for elevating the table, and means controlled by the movement of the swinging frame for controlling the table-elevating means.

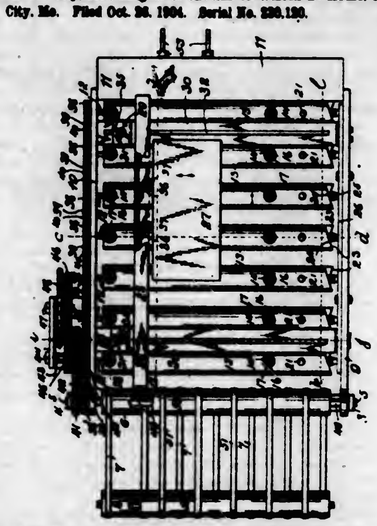
39. In a paper-feeder, the combination with a table adapted to support a pile of paper, of a support, a swinging frame pivotally connected to said support and having two supporting-shoes and adapted to alternately rest upon the pile of paper, and a sheet separating and detaching mechanism mounted on and movable with said swinging frame.

40. In a paper-feeder, the combination with a table adapted to support a pile of paper, of a support, a swinging frame pivotally connected to said support and adapted to rest upon the pile of paper, two shoes pivotally mounted on said frame, means for swinging said shoes alternately so that they may alternately support the frame on the pile of paper, means for forcing out one or more of the top sheets from under one shoe and depositing the said sheet or sheets upon said shoe, means for gripping said deposited sheets and throwing back on the pile all but one, and means for seizing said retained sheet, and stripping it from the pile.

41. In a paper-feeder, the combination with a table adapted to support a pile of paper, of a support, a frame pivotally connected with said support, two shoes pivotally mounted on said frame and adapted to rest alternately upon the pile of paper for supporting thereon said frame, a rubbing device rotatively mounted on the frame and adapted to rub the top sheet or sheets out from under one of said shoes and drop them upon the said shoe, means for swinging the shoe supporting the sheets so as to lift the sheets from the pile, a stripping mechanism carried by the frame for seizing and stripping from the pile sheets raised by one of the shoes, and a sheet-separating mechanism comprising a friction-pad, a device for pressing the raised sheets upon the said pad, a rotary friction-disk for rubbing against the sheets carried on the pad, means for rotating said disk, means for relatively moving the disk and pad toward and from each other, and means for moving said pad, friction-disk and pressing device between the shoe supporting the sheets and the stripping mechanism.

42. In a paper-feeder, the combination with a vertical post, of means for rotating said post, a transverse shaft rotatively mounted in said post and provided with a crank-arm, means for rotating said shaft, a second shaft rotatively mounted in said crank-arm, means for rotating said second shaft, a friction-disk mounted on said second shaft, a friction-pad mounted on the crank-arm and movable toward and from the friction-disk, means for so moving said pad, a spring carried by said crank-arm and adapted to press against said pad, and means for raising one or more of the top sheets from a pile and depositing them between said pad and spring and friction-disk.

810,892. SHEET-REGISTERING MACHINE. HARRY BRADSHAW, Kansas City, Mo., assignor of one-half to Warren D. Hoard, Kansas City, Mo. Filed Oct. 26, 1904. Serial No. 230,120.



Claim.—1. A sheet supporting and registering device revoluble around an axis and movable simultaneously lengthwise thereof and disposed during a portion of each revolution out of contact with the sheets to be registered.

2. A sheet supporting and registering device revoluble around an axis and reciprocable simultaneously lengthwise thereof and disposed during lengthwise movement in one direction out of contact with the sheets to be registered.

3. A sheet supporting and registering device comprising two devices revoluble around a common axis and movable simultaneously in opposite directions lengthwise of the axis.

4. A sheet supporting and registering cylindrical roller rotatable around its axis and comprising two longitudinal members movable simultaneously in opposite directions lengthwise of the axis of the roller.

5. The combination with a sheet-supporting device, of means for simultaneously revolving the said device and moving it lengthwise of the axis of revolution, the sheet-supporting device being disposed during a portion of each revolution out of contact with the sheets to be registered.

6. The combination with a sheet-supporting device, of means for revolving said device and simultaneously reciprocating it lengthwise of the axis of revolution, the sheet-supporting device being disposed during lengthwise movement in one direction out of contact with the sheets.

7. The combination with a sheet-supporting device comprising two members, of means for revolving said members around a common axis and simultaneously moving them in opposite directions lengthwise of the axis.

8. The combination with two sheet-supporting members, of means for revolving said members around a common axis, and means for simultaneously reciprocating said members in opposite directions lengthwise of the axis.

9. The combination with a sheet-supporting cylindrical roller comprising two longitudinal diametrically opposite members, of means for rotating said roller, and means for simultaneously reciprocating in opposite directions lengthwise of the axis of the roller, said two members.

10. A sheet-supporting roller comprising a longitudinal support, two longitudinal members disposed on diametrically opposite sides of said support and slidable lengthwise thereon, and means by which lengthwise movement of one member in one direction imparts movement in the opposite direction to the other member.

11. A sheet-supporting roller comprising a rotatable shaft, two longitudinal members slidable lengthwise on and rotatable with said shaft, and means by which said members may be reciprocated simultaneously lengthwise in opposite directions.

12. A sheet-supporting roller comprising a rotatable shaft, two longitudinal members slidable lengthwise on said shaft and rotatable therewith, and a lever fulcrumed on the shaft and having its ends engaging respectively said members.

13. A sheet-supporting roller comprising a rotatable shaft, two members disposed diametrically opposite thereon and slidable lengthwise on and rotatable with the shaft, and a lever pivoted transversely on the shaft and having its ends pivotally connected with said members respectively.

14. A sheet-supporting roller comprising a rotatable shaft, two longitudinal members disposed diametrically opposite and slidable lengthwise on and rotatable with the shaft, each member being provided with a radial hole, and a lever pivoted transversely on the shaft and having its ends mounted respectively in the holes in said members.

15. A sheet-supporting roller comprising a rotatable shaft, two semicylindrical longitudinal members slidable lengthwise on and rotatable with the shaft and provided each with a round hole on its inner side, and a lever pivoted transversely upon said shaft and having spherical ends mounted respectively in said round holes in said members.

16. The combination with a sheet-supporting device, of means for revolving said device around an axis, the device being a portion of each revolution out of contact with the sheets, means for simultaneously moving said device lengthwise of the axis, and a side guard disposed transversely of said axis.

17. The combination with a sheet-supporting device, of means for revolving said device around an axis, means for reciprocating said device lengthwise of the axis, the device being disposed during lengthwise movement in one direction out of contact with the sheets, and a side guide disposed transversely of the axis.

18. The combination with a sheet-supporting device, of means for revolving said device around an axis, a side guide disposed transversely to the axis, means for moving said device toward the side guide when the device has been revolved to a position in which the sheet is supported thereby, and means for moving said device in the opposite direction.

19. The combination with two sheet-supporting devices revoluble around a common axis, of means for so revolving said devices, a side guide disposed transversely to the axis of revolution of said devices, and means for simultaneously moving said devices lengthwise of said axis and in opposite directions to each other.

20. The combination with two horizontal devices adapted to alternately support a sheet of paper, of means for revolving said devices around a common axis, means for moving each of said devices lengthwise of said axis in a certain direction when it is in position to support a sheet, and means for moving said devices lengthwise in the opposite direction.

21. The combination with two horizontal devices adapted to alternately support a sheet of paper, of means for revolving said devices around a common axis, a side guide disposed transversely of said axis, means for moving each of said devices lengthwise of the axis toward said guide when it is positioned to support the sheet, and means for retracting said devices lengthwise in the opposite direction.

22. The combination with a sheet-supporting device, of means for revolving said device around an axis, means for moving said device lengthwise of the axis, and a side guide disposed transversely to the axis and adjustable to and fro in a direction parallel with the axis.

23. The combination with two horizontal devices adapted to alternately support a sheet of paper, of means for revolving said devices around an axis, means for moving each of said devices lengthwise in a certain direction when it is in position for supporting a sheet, and means for moving each of said devices in the opposite direction lengthwise when it is in position not supporting a sheet.

24. The combination with two horizontal devices adapted to alternately support a sheet of paper, of means for revolving said devices around an axis, a side guide disposed transversely to said axis, means for moving each of said devices toward said side guide and lengthwise of said axis when the device is positioned so as to support a sheet, and means for moving each of said devices lengthwise away from the guide when the device is in position not adapted to support the sheet.

25. The combination with two devices adapted to alternately support a sheet, of means for revolving said devices around an axis, a side guide disposed transversely to the axis and adjustable in a direction parallel with the axis, and means for simultaneously moving said devices in opposite directions lengthwise of said axis.

26. The combination with two devices adapted to support alternately a sheet of paper, of means for revolving said devices around an axis, a side guide adjustable lengthwise of the axis, means for moving each of said devices toward the guide lengthwise of the axis when said device is revolved to a position adapted to support the sheet, and means for moving each of said devices away from the guide when it is in position not adapted to support a sheet.

27. The combination with a plurality of devices adapted to support thereon a sheet of paper, of means for rotating each of said devices around its axis, said devices being disposed parallel with each other, and means for imparting lengthwise movement to each of said devices.

28. The combination with a plurality of devices adapted to support thereon a sheet of paper, said devices being disposed parallel with each other, of means for rotating each of said devices around its axis, and means for reciprocating said devices lengthwise.

29. The combination with a plurality of rollers comprising each two members disposed parallel with each other and adapted to alternately support a sheet of paper, of means for rotating said rollers each around its axis, and means for reciprocating lengthwise in opposite directions the two members of each of said rollers.

30. The combination with a plurality of rollers comprising each two longitudinal members adapted to support alternately a sheet of paper, of means for rotating each of said rollers, means for reciprocating simultaneously lengthwise in opposite directions the two members of each roller, and a side guide disposed transversely to said rollers.

31. The combination with a plurality of devices adapted to support thereon a sheet of paper, of means for imparting rotation to each of said devices, means for reciprocating said devices lengthwise of their several axes, a side guide adjustable lengthwise of and disposed parallel with the axes of said devices.

32. The combination with a sheet-supporting roller comprising two longitudinal members movable lengthwise parallel with each other, a shaft on which said members are mounted, of means for rotating said shaft, and means for reciprocating said members simultaneously in opposite directions lengthwise of the shaft.

33. The combination with a sheet-supporting roller comprising two semicylindrical members disposed parallel with each other and having each a beveled end, a shaft on which said members are mounted, a lever pivoted to the shaft and having its ends engaging respectively said members, of means for rotating said shaft, and a device for engaging alternately the beveled ends of said members for forcing them lengthwise when the shaft is rotated.

34. The combination with a plurality of rollers comprising each two longitudinal members, a shaft on which the members are longitudinally slidable, a lever pivoted to the shaft and having its ends engaging said members respectively, of means for rotating said shafts, and means for engaging alternately the members of each roller and forcing them lengthwise on the shaft carrying them.

810,393. RAILROAD-TIE. ROBERT B. CAMPBELL, Joliet, Ill., assignor of one-half to himself and one-half to Alexander F. Banks, Evanston, Ill. Filed Oct. 12, 1905. Serial No. 282,622.

Claim.—1. In a railroad-tie, the combination with a tie-body formed of plastic material, of a substantially U-shaped support embedded in said body, said support arranged with its open ends toward the ends of the tie, and a cover-plate resting upon said support, substantially as specified.

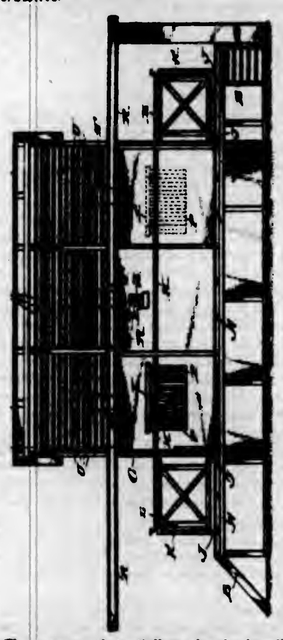
2. In a railroad-tie, the combination of a tie-body formed of plastic material, an interior core, and a substantially U-shaped support surrounding said core, said support arranged with its open ends toward the ends of the tie, with a cover-plate attached to said support, substantially as specified.

3. In a railroad-tie, the combination with a tie-body formed of plastic material, of a substantially U-shaped support embedded in said body, said support arranged with its open ends toward the ends of the tie and provided with projections, in combination with a cover-plate attached to said support, substantially as specified.

4. In a railroad-tie, the combination with a tie-body formed of plastic material, of a substantially U-shaped support embedded in said body, and a cover-plate resting upon said support, said cover-plate having flanges at opposite edges, substantially as specified.

5. In a railroad-tie, the combination with a tie-body formed of plastic material, of a substantially U-shaped support embedded in said body, and provided at its upper ends with tongues, and a cover-plate adapted to be secured to said support by said tongues, substantially as specified.

810,394. PROCESS OF OXIDIZING FABRICS. REINHARD CLEFF, Rosenthal, near Barmen, Germany, assignor to Susquehanna Silk Mills, New York, N. Y., a Corporation of Pennsylvania. Filed Mar. 13, 1905. Serial No. 249,776.



Claim.—The process substantially as herein described of oxidizing woven material, which has been treated with suitable chemicals giving an oxidizing reaction when heated, which consists in first saturating the said material and starting the oxidation in a suitable apparatus, then mechanically introducing the so-treated material, as it comes from the first apparatus, in a body all at once into a highly-heated and moist atmosphere in a closed chamber initially heated to a high degree, leaving said body of material in said chamber for a relatively short time while regulating the temperature to maintain the said initial high temperature of the chamber and substantially the same degree of moisture of the air therein from the beginning to the end of the operation, thereby obtaining substantially the same degree of oxidation throughout the reaction and finally mechanically removing the whole of said body of material at once from the chamber without substantially reducing the temperature of said chamber or altering the said degree of moisture of the air therein.

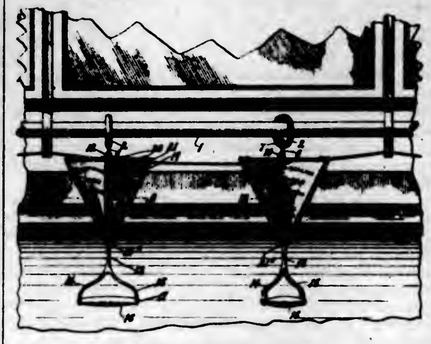
810,395. HANGING-STRAP FOR PASSENGER-VEHICLES. JOHN S. COLLINS, New York, N. Y., assignor, by direct and mesne assignments, to American Car Strap Advertising Company, New York, N. Y., a Corporation of South Dakota. Filed Mar. 6, 1905. Serial No. 248,553.

Claim.—1. A hanging-strap for vehicles comprising a support ing-ring provided with a bearing-cushion in its upper portion, an advertising-body suspended from the ring in free rotary adjustment and a handle depending from the advertising-body.

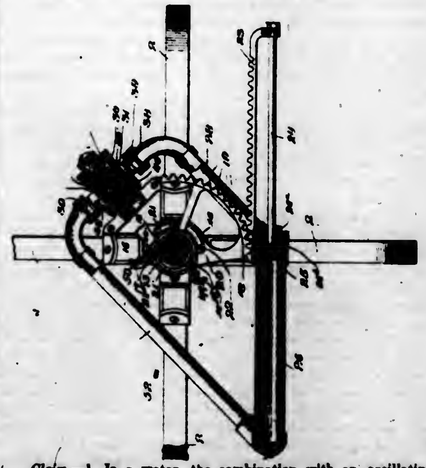
2. A hanging-strap for vehicles comprising a suitable primary support, a pyramidal body for the reception of advertising matter on all of its faces and a handle depending from the pyramidal body.

3. A hanging-strap for vehicles comprising a suitable primary support, an inverted pyramidal body for the reception of advertising matter on all of its faces depending from the primary support and a handle depending from the apex of the pyramid.

4. A hanging-strap for vehicles comprising a suitable primary support, a pyramidal body depending from the primary support, a handle depending from the pyramidal body and means for holding advertising-cards in removable adjustment on the several faces of the pyramidal body.



810,396. MOTOR. CHARLES W. CRANER and HARRY C. HAAK, Scranton, Pa. Filed Jan. 18, 1905. Serial No. 241,253.



Claim.—1. In a motor, the combination with an oscillating frame, a suitable support therefor, and a shaft retaining the frame in position, of a suitable collar surrounding said shaft, a spring surrounding said collar, means retained by the said frame engaging said spring, means for oscillating said spring, and devices for controlling said oscillating means, substantially as described.

2. In a motor, the combination with an oscillating frame, supporting means therefor, and a shaft retaining the frame in position, of a spring surrounding said shaft, devices carried by said frame engaging said spring, means for oscillating said spring, and means carried by the frame controlling said oscillating means, substantially as described.

3. In a motor, the combination with an oscillating frame, of a spring, means on the frame engaging said spring, means for oscillating the spring, said means comprising a collar about which the spring is coiled, and devices carried by the frame controlling said oscillating means.

4. In a motor, the combination with an oscillating frame, of a suitable mounted collar, a collar spaced therefrom, a spring arranged between said collars, connections between said frame and spring, means for oscillating said collars, and means carried by the frame controlling the oscillating means, substantially as described.

5. In a motor, the combination with a suitable frame, of inner and outer connected collars, a spring carried by said collars, means for imparting movement from said spring to said frame, means for

oscillating said collars, and devices on said frame controlling said oscillating means, substantially as described.

6. In a motor, the combination with an oscillating frame, a suitable support therefor, and a vertical shaft retaining said frame in position upon its support, of a collar surrounding said shaft, a coil-spring surrounding said collar, means depending from said frame engaging the ends of said spring, means for oscillating said spring, and means carried by said frame controlling said oscillating means, substantially as described.

7. In a motor, the combination with an oscillating frame, supporting means therefor, and a shaft retaining said frame in position upon its support, of a spring coiled about said shaft, a collar partially inclosing said spring, means carried by said frame engaging the ends of said spring, means for oscillating said collar whereby said spring will be moved, and means carried by said frame controlling said oscillating means, substantially as described.

8. In a motor, the combination with an oscillating frame, a support therefor, and a shaft retaining said frame in position upon its support, of a collar surrounding said shaft, a collar spaced from the first-mentioned collar and formed integral therewith and partially inclosing the same, a coil-spring surrounding the first-mentioned collar and being partially inclosed by the second-mentioned collar, means carried by said frame engaging the said spring, means for oscillating said collars, and means carried by the frame for controlling the oscillating means, substantially as described.

9. In a motor, the combination with an oscillating frame, and a shaft supporting the same in position, of a collar surrounding said shaft, an outer collar spaced from and formed integral with said collar and partially inclosing the same, a coil-spring interposed between said collars and having its ends projecting beyond the outer collar and bent, lugs depending from said frame and engaging the bent ends of said spring, means for oscillating said collars, and means carried by said frame controlling said oscillating means, substantially as described.

10. In a motor, the combination with a suitable oscillating frame, a shaft supporting the same, a spring spaced from said frame and coiled about said shaft, connections between said frame and spring, means for oscillating said spring, and governing devices carried by said frame for controlling the oscillating means, substantially as described.

11. In a motor, the combination with an oscillating frame, a shaft carried thereby, of a collar surrounding said shaft, a second collar spaced outside the first collar and partially inclosing the same, a spring disposed between said collars and having its ends projecting beyond the outer collar, devices arranged on the frame engaging said projecting ends, means for oscillating said collars, and means on the frame controlling said oscillating means, substantially as described.

12. In a mechanism of the class described, the combination with a suitable oscillating frame, of a cylinder, a piston operating therein, a segment actuated thereby, a slot being formed in said segment, guiding means extending through said slot and engaging the segment for retaining the same against lateral play, means for limiting said segment in its movement, and means for communicating motion from said segment to said frame, substantially as described.

13. In a motor, the combination with a suitable oscillating frame, of a cylinder and piston operating therein, a segment operated by said piston formed with a segment-slot, guiding means extending through said slot and limiting said segment against lateral play, a second slot being formed in said segment, limiting means projecting through said last-mentioned slot, and means for communicating motion from said segment to said frame, substantially as described.

14. In a mechanism of the class described, the combination with a horizontal oscillating frame, adapted to move on a vertical axis, cylinder, piston, and means communicating motion from said piston to said frame, of a valve having its axis of movement at right angles to the axis of said frame controlling the supply of power medium to said cylinder, an arm carried by the stem of said valve, lugs projecting from said arm in different vertical planes, and lugs carried by said frame at different distances from the pivot-point thereof and moving in different circular lines, each in its movement crossing the vertical plane of one of the lugs upon the said valve-arm, substantially as described.

15. The combination with a frame, of a cylinder, a detachable plug inserted in the frame and forming one head to the cylinder, the other head being formed by the frame; a valve-seat and valve in the frame, ports in said valve and seat adapted to register and communicate with said cylinder, and outlet and inlet ports to said valve-seat.

16. The combination with a frame, of a cylinder, a screw-plug inserted in the frame and forming one head of the cylinder, the other head being formed by said frame; a piston in the cylinder, ports at each side of the piston communicating with a valve-seat in the frame, inlet and outlet ports to the valve-seat and a rotatable valve located in said seat and having ports adapted to register with the ports in said seat whereby communication may be established with the ports in the cylinder.

17. The combination of a support or frame carrying a tub adapted to be oscillated, of a cylinder having a piston, piston-rod, and ports therein, a frame for said cylinder, said cylinder secured in the frame, a screw-plug forming one head of the cylinder, the other head being formed by said frame, a valve-seat communicating with said cylinder-ports, a rotatable valve having ports located in said seat, projections on said valve and means on the tub for striking said valve projections and revolving said valve, whereby communication may be established between said valve and cylinder.

18. The combination of a support or frame carrying a tub adapted to be oscillated, a cylinder secured in a motor-frame, a detachable plug forming one head of the cylinder, the other head being formed by the frame, piston, piston-rod, and ports in said cylinder, a valve-seat communicating with said cylinder-ports, a rotatable valve located in said seat and provided with ports, a bearing-rod located in the center of the support, connections from the piston-rod to the tub, whereby said tub is oscillated, projections on said valve, and means on said tub for striking said projections and actuating the valve for the purpose set forth.

19. The combination with a frame, of a cylinder seated therein, detachable means securing said cylinder in the frame and forming one head of the cylinder, a piston and piston-rod in the cylinder, ports at each side of the piston, a valve-seat in the frame, passages connecting said valve-seat and cylinder at each side of the piston, a rotatable valve located in said seat and provided with ports, means for revolving the valve, and means for limiting the movement of the valve, whereby communication is established between the valve and the ports in the cylinder.

20. The combination of a support or frame carrying a tub adapted to be oscillated, a cylinder seated in a motor-frame and secured thereto, a detachable plug forming one head of the cylinder, a piston and piston-rod, ports in said cylinder and a valve-seat communicating with said ports, projections on said valve in the path of movement of a part on said tub, for rotating said valve, a pointer on the rotatable valve and stops on the fixed part of the motor against which said pointer contacts to limit the movement of the valve in its revolutions.

21. The combination with the frame, of a cylinder, a piston, a detachable plug inserted in the frame and forming one head of the cylinder, the other cylinder-head being formed by the frame; a valve-seat and valve in the frame, ports in said valve and seat adapted to communicate with the cylinder, devices on the valve for opening and closing communication on either side of said piston and means for operating said devices.

22. The combination with the frame, of a cylinder, a detachable plug secured in the frame, and forming one head thereof the other cylinder-head being formed by the frame, a valve-seat and valve in the frame, said valve consisting of the tapered portion provided with ports, a stem extended from said tapered portion, a sleeve having spurs rigidly connected to said stem, an immovable bearing-sleeve to the stem, a pointer on the first-mentioned sleeve, and lugs for limiting the movement of the valve.

23. The combination with the frame, of a cylinder, a screw-plug secured in the frame and forming one head of the cylinder, the other head being formed by the frame, a valve and valve-seat in the frame communicating with the cylinder, said valve consisting of the valve portion proper provided with ports, a stem, the spurred sleeve connected to said stem, a bearing-sleeve between the spurred sleeve and valve portion, and means for limiting the movement of the valve.

24. The combination with the frame, of a cylinder, said cylinder being detachably connected to the frame, one head containing a stuffing-box, the other head being formed by the frame, a valve and valve-seat in the frame communicating with the cylinder, a sleeve secured to the stem of the valve having spurs thereon and means for striking said spurs to rotate the valve, a pointer on said sleeve, a bearing-sleeve, and lugs for limiting the rotation of the valve.

25. In a mechanism of the class described, the combination of a frame having a horizontal oscillating movement, a vertical shaft, a segmental rack mounted on said shaft, a spring between the rack and the frame, to move said frame in reverse or opposite directions, a cylinder, piston, and means for controlling the piston, and a rack connected to the piston for actuating the segment.

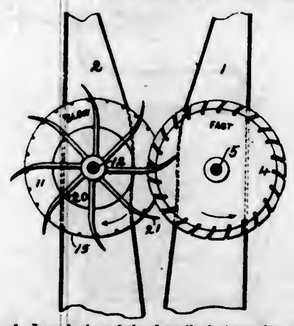
26. In a mechanism of the class described, the combination with a pivoted frame, a cylinder, a piston within said cylinder a spring interposed between said frame and piston for imparting motion to the frame from the piston, means for controlling the pressure-supply to the cylinder, and means actuated by said frame for operating said controlling means.

27. The combination with an oscillating frame, a cylinder, and a reciprocating piston operating in said cylinder, of means for transforming the reciprocatory movement of said piston to an oscillating movement, a spring for conveying movement from said transforming means to said frame, and means actuated by the frame for governing the pressure supplied to said cylinder.

28. The combination with an oscillating frame, a relatively short cylinder, and a piston therefor, of a spring interposed between said piston and frame for conveying movement from the piston to the frame, whereby said frame is free to move to a greater extent than the extent of movement imparted by the piston.

29. In a mechanism of the class described, the combination with an oscillating frame, of a piston, means for supplying pressure thereto, means governing the pressure-supply of the piston, a spring for imparting movement from the piston to the frame, whereby the frame, by acting against the pressure of the spring, is free to move to a greater extent than the movement imparted directly by the piston, and means carried by said frame for actuating said pressure-controlling means, at each stroke of the frame, prior to the completion of the stroke thereof.

810,397. **ROTARY CUTTER AND TOPPER.** FRANK DENNISON, Markesan, Wis. Filed Dec. 21, 1904. Serial No. 237,085.



Claim.—1. In a device of the described class, the combination of a set of partially-overlapping rotary disks driven at different speeds; driving connections for each of said disks arranged to impart a different speed to one of the disks from that of the other, and a set of radially-projecting gathering-fingers rotating on the same axis with the more slowly moving disk and projecting over the inner edge of the more rapidly moving disk.

2. In a device of the described class, the combination of a set of rotary disks; a supporting-shaft for each of said disks; a set of gathering-fingers connected with one of said shafts; and means for driving said shafts at different rates of speed, the disk on one shaft having its inner edge interposed between the disk and gathering-fingers on the other shaft.

3. In a device of the described class, the combination of a set of rotary disks; a supporting-shaft for each of said disks; a set of gathering-fingers connected with one of said shafts; and means for driving said shafts at different rates of speed, the disk on one shaft having its inner edge interposed between the disk and gathering-fingers on the other shaft, and each of said disks having its margin beveled in the direction of the other.

4. In a device of the described class, the combination of a set of rotary disks; a supporting-shaft for each of said disks; a set of gathering-fingers connected with one of said shafts; and means for driving said shafts at different rates of speed, the disk on one shaft having its inner edge interposed between the disk and gathering-fingers on the other shaft, and each of said disks having its margin beveled in the direction of the other and slotted to form a series of teeth having an angular rake opposite that of disk rotation.

5. In a device of the described class, the combination of a set of driving-shafts; means for driving one of the shafts at a greater speed than the other; a disk mounted on the slower shaft; and a set of gathering-fingers mounted on said slower shaft above said disk; a disk mounted on the faster shaft and partially interposed between the disk on the slower shaft and said gathering-fingers; said disks having their margins beveled, each in the direction of the other and arranged to travel in approximate contact.

6. In a device of the described class, the combination of a set of driving-shafts; means for driving one of the shafts at a greater rate of speed than the other; a disk mounted on the slower shaft; and a set of gathering-fingers mounted on said slower shaft above said disk; a disk mounted on the faster shaft and partially interposed between the disk on the slower shaft and said gathering-fingers; said disks having their margins beveled each in the direction of the other, and arranged to travel in approximate contact; and disks being provided with marginal cutting-teeth.

810,398. **NON-REFILLABLE BOTTLE.** JOHN M. DUNKLE, Rolla, Pa. Filed May 3, 1905. Serial No. 258,469.

Claim.—A bottle or like receptacle having its neck contracted upon its inner side to provide a valve-seat, and having an inner annular extension above the said seat contracted at its lower end, and having a series of openings around its upper portion, and a compressible valve of larger diameter than the contracted end of said annular extension and forced therethrough for coöperation with the valve-seat and prevented from withdrawal by expansion after clearing the said contracted annular extension.

810,399. **HORSESHOE.** AARON L. DURR, Richland Center, Pa. Filed Mar. 26, 1905. Serial No. 252,000.

Claim.—1. In a horseshoe, a plate bearing against the rear face of the toe-calk and carrying supplemental calks, and having upturned ends bearing against the outer face of the shoe, and means for detachably clamping said plate to the shoe.

2. In a horseshoe, a plate bearing against the rear face of the toe-calk and carrying supplemental calks, and having upturned ends bearing against the outer face of the shoe, a clamp member bearing upon said plate and with extended ends bearing upon the upper face of the shoe, and means for clamping said member to said plate.

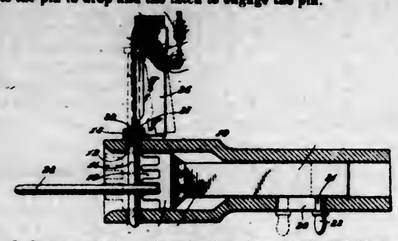
3. In a horseshoe, a plate bearing against the rear face of the toe-calk and carrying supplemental calks, and having upturned ends bearing against the outer face of the shoe, a clamp member bearing upon said plate and with extended ends bearing upon the upper face of the shoe, and a bolt connecting said plate and clamp member.

810,400. **CAR-COUPLING.** LEWIS P. ELLIOTT, Jackson Center, Ohio. Filed Aug. 14, 1905. Serial No. 274,120.

Claim.—1. In a car-coupler, a vertically-sliding pin, a latch pivoted above and arranged to hold the pin to its seat, and a cable passing through an arm of the latch and secured to the pin and arranged to disengage the latch and raise the pin.

2. A car-coupler comprising a link, a hollow draw-head having a slot formed in the walls thereof, a pin vertically slidable adjacent the end of the draw-head, a block movable longitudinally within the

draw-head to a position beneath the pin when the latter is raised and provided at one end with a plurality of spaced link-receiving grooves and at the opposite end with a depending operating-knob engaging the slot in the draw-head, means at the top of the car to raise the pin and so arranged that the contact of the link moves the block and permits the pin to drop and the latch to engage the pin.



3. In a car-coupler, a draw-head, a pin vertically slidable in the draw-head, a latch pivoted above the draw-head and arranged to contact with the upper end of the pin to hold the latter to its seat and a cable so connected with the latch and pin that a pull on the cable first disengages the latch and then raises the pin.

4. In a car-coupler, a draw-head, a pin vertically slidable in the draw-head, an upright rigidly upstanding from the draw-head, a latch pivotally mounted upon the upright and arranged to contact with the upper end of the pin and hold the latter to its seat and having an arm offset therefrom, a cable passing through the arm and connected to the link.

5. A car-coupler comprising a link, a hollow draw-head, a pin vertically slidable in the draw-head, an upright rigidly upstanding from the draw-head, a latch pivotally mounted upon the upright and arranged to contact with the upper end of and hold the pin to its seat, a cable so connected with the latch and pin that a pull upon the cable first disengages the latch and then raises the pin, a block slidably mounted in the draw-head, means for sliding the block to support the pin when raised and so arranged that the contact of the link moves the block and permits the pin to drop and the latch to engage the pin.

6. A car-coupler comprising a link, a hollow draw-head, a pin vertically slidable in the draw-head, an upright rigidly upstanding from the draw-head, a latch pivoted adjacent the top of the upright and arranged to contact with the upper end of and hold the pin to its seat, said latch having an arm offset from its upper end, a cable passing through the arm and connected to the pin, means disposed at each side and the top of the car for pulling the cable to disengage the latch and raise the pin, a block slidably mounted in the draw-head, and means for sliding the block to support the pin when raised and so arranged that the contact of the link moves the block and permits the pin to drop and the latch to engage the pin.

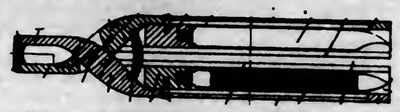
810,401. STEREOSCOPE. PROSPER D. FERIS, Chicago, Ill. Filed Aug. 17, 1905. Serial No. 274,604.

Claim.—1. In a device of the class described, the combination of a two-part case, one member forming the front end bottom, with lenses located in said front, a member forming the rear and top into which cards may be removably inserted, a slide fitted to move in the bottom portion of said first-named member, said slide being jointedly attached to said secondary member.

2. In a device of the class described, the combination of a two-part case, one member forming the front and bottom, said bottom consisting of two parallel members with an intervening space for the reception of a slide, a slide fitted between said members, and a member forming the rear end top, which member is jointedly connected to said slide.

3. A device of the class described in which is combined a two-part case, one member of which forms the front end bottom while the other is jointedly connected therewith to form the rear end top, a hollow partition formed at right angles to the front and extending rearwardly therefrom midway between the ends and an adjustable slide fitted thereto.

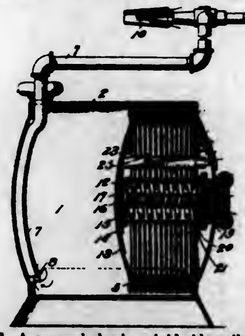
810,402. NAIL-CLIPPER. ADOLPH H. FRIESS, New York, N. Y. Filed Jan. 20, 1905. Serial No. 242,219.



Claim.—1. A device of the class described comprising two handle members having shanks at one end which are pivoted together in the manner of a pair of shears, said shanks being provided with projecting jaws having inwardly-directed cutting edges, said handle members being also provided with longitudinal spaces which open outwardly and with slides which are mounted therein and provided with different tools, substantially as shown and described.

2. A device of the class described, comprising two handle members having curved shanks at one end pivoted together in the manner of a pair of shears, said shanks being provided with projecting jaws having inwardly-directed cutting edges, said handle members being also provided with longitudinal chambers which open outwardly and tool-slides mounted therein, said handle members being also provided with longitudinal slots, and devices passing through said slots and connected with said slides, substantially as shown and described.

810,403. RESERVOIR FOR GASOLENE AND OTHER VAPOR BURNERS. WESTON M. FULTON and WILLIAM H. RICHARDS, Knoxville, Tenn., assignors to The Fulton Company, Knoxville, Tenn., a Corporation of Maine. Filed Feb. 20, 1905. Serial No. 246,561.



Claim.—1. A reservoir having rigid side walls and a rigid end wall, a collapsible and expansible vessel closing the opposite end of said reservoir and movable within the latter, a rigid supporting-plate fast to the end of the reservoir, a threaded rod, one end having a bearing in said plate and provided with a nut traveling along said rod, and a member fast to the collapsible vessel and engaging said nut, whereby the rotation of said rod causes the said vessel to collapse or expand.

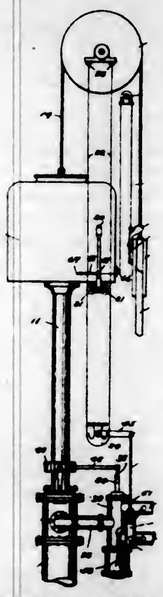
2. A reservoir having rigid side walls and a rigid end wall, a collapsible and expansible vessel closing the opposite end of said reservoir and movable within the latter a screw-threaded rod and supporting means for the outer end of the same, a nut on said rod engaging a member on said collapsible vessel, and a shoulder of end plate on said rod to limit the outward traverse of said vessel.

3. A reservoir having rigid side walls and a rigid end wall, a collapsible and expansible vessel closing the opposite end of said reservoir and movable within the latter, a screw-threaded rod, and supporting means for the outer end of the same, a nut on said rod, and a member connecting the nut with said vessel, and a spring intermediate said nut and vessel for placing the liquid in the reservoir under pressure.

4. A reservoir having rigid side walls and a rigid end wall, a collapsible and expansible vessel closing the opposite end of said reservoir movable within the latter and having a rigid end wall, a screw-threaded rod and supporting means for the outer end of the same, a nut on said rod, and a member connecting the nut with the end wall of said vessel, a spring intermediate said nut and wall, and a spirally-slotted tube fast to the latter and engaging a registering device.

5. A reservoir having a collapsible and expansible closure for displacing fluid from the same, a revolubly screw-threaded operating-rod provided with a traveling nut, a fluid-compression spring one end of which rests against said closure and the other end against said nut, a slotted member fast to said closure and engaging said nut to restrain the same from rotation, and to limit the extent of compression of said spring upon said fluid.

810,404. RETARDING DEVICE FOR PLUNGER-ELEVATORS. FLOYD C. FURLOW, Montclair, N. J., assignor to Otis Elevator Company, East Orange, N. J., a Corporation of New Jersey. Filed Oct. 31, 1904. Serial No. 230,767.



Claim.—1. In a hydraulic elevator, the combination with a plunger and a car, of a retarding device for such plunger, and means controlled from the car for applying and releasing such retarding device.

2. In a hydraulic elevator, the combination with a car and a plunger, of a retarding device for such plunger, and means within the control of the operator on the car for applying and releasing such retarding device.

3. In a hydraulic elevator, the combination with a plunger and a car, of a retarding device for the plunger, and means controlled from the car for starting and stopping said car and for applying and releasing said retarding device.

4. In a hydraulic elevator, the combination with a plunger and a valve, of a retarding device for the plunger, said retarding device being actuated by the movement of the valve.

5. In a hydraulic elevator, the combination of a plunger, a car attached to the plunger, a valve, a retarding device for the plunger actuated by the valve, and means for controlling said valve from the car.

6. In a hydraulic elevator, the combination of a plunger, a reversing-valve for controlling the movement of the said plunger, a retarding device for the plunger, means controlled from the car for actuating said reversing-valve, and connections from the said valve to the retarding device for actuating the same.

7. In a hydraulic elevator system, the combination of a plunger, a car attached to the plunger, a counterweight attached to the car, a retarding device for the plunger, a retarding device on the counterweight, and a single means for actuating said retarding devices from the car.

8. In a hydraulic elevator the combination of a plunger and a car, a retarding device for the plunger, and means situated upon the car for controlling the starting, stopping and reversing the movement of the car and actuating the retarding device at the same time.

9. The combination with a car, of a counterweight and a plunger connected respectively to the top and bottom of the car, a gripping device for the plunger, means for controlling the movements of the car and plunger, and means for operating said gripping device and controlling means from the car.

10. The combination with a car, of a counterweight, a plunger for said car, means for controlling the movement of the car and plunger, a brake for said plunger, and a single means for operating said controlling means, and a lever for actuating said operating means.

11. The combination with a car, of a counterweight, a plunger connected to the car, means for controlling the movement of said car and plunger, a brake for said counterweight, and means for operating said brake and controlling means from the car.

12. In an elevator, the combination with a car and means for moving same, of a counterweight, a retarding device for the counterweight, and means for positively actuating said retarding device.

13. In an elevator, the combination with a car and means for moving same, of a counterweight, a retarding device for the counterweight, and means controlled from the car for applying and releasing such retarding device.

14. In an elevator, the combination with a car, of a counterweight therefor, a retarding device for such counterweight, and means within the control of the operator on the car for applying and releasing such retarding device.

15. In an elevator, the combination with a car and its counterweight, of a retarding device for the counterweight, and means controlled from the car for starting and stopping said car and for applying and releasing said retarding device.

16. In a hydraulic elevator, the combination with a car and a plunger, of a counterweight, valve mechanism for controlling the movement of said car and plunger, a brake for the counterweight, connections for operating said valve mechanism and said brake, and a single means for actuating said connections from the car.

17. In a hydraulic elevator, the combination with a car and a plunger, of a counterweight, a brake for said counterweight, and means actuated from the car for controlling the starting, stopping and reversing of the movement of the car and plunger and actuating said brake substantially at the same time.

18. In an elevator, the combination with a car and a counterweight connected thereto, of guides for said counterweight, brake-shoes, a toggle connected to the brake-shoes, a resilient means for normally holding said brake-shoes away from the guides, and means actuated from the car for operating said toggle against the action of said resilient means to apply said brake-shoes to stop the car and counterweight.

19. In an elevator, the combination with a car and its counterweight, of a brake for the counterweight, brake-applying means, a spring for normally holding said brake and brake-applying means in releasing position, a flexible connection between the brake-applying means and the car, a device on the car for exerting a pull on said flexible connection to effect the application of the brake on the counterweight, and a spring connected to said device to counteract the spring on the counterweight.

20. In a hydraulic elevator, the combination with a plunger and a car, of a gripping device for said plunger, and means for releasing and controlling the application of said gripping device from the car.

21. In a hydraulic elevator, the combination with a plunger and a car, of a brake for said plunger, means for controlling the movement of the car, and means connected to the car for operating said brake to release or apply the same.

22. In a hydraulic elevator, the combination with a plunger and a car, of a brake for said plunger, and a cam actuated from the car for operating said brake.

23. In a hydraulic elevator, the combination with a plunger and a car, of a brake for said plunger, lugs extending from said brake, a cam for coacting with said lugs to apply the brake, and means operated from the car for moving said cam.

24. In a hydraulic elevator, the combination with a plunger and a car, of a cylinder for said plunger, means for controlling the flow of fluid to said cylinder, and means actuated from the car for operating said fluid-controlling means and for applying said brake.

25. In a hydraulic elevator, the combination with a plunger and a car, of a cylinder for said plunger, fluid-controlling means for said plunger, a brake for the plunger and mounted on the cylinder, and means actuated from the car for operating said fluid-controlling means and applying and releasing said brake.

26. In a hydraulic elevator, the combination with a plunger and a car, of a retarding device for such plunger, means for applying said retarding device, and manually-operable means for positively actuating said retarding-device-applying means.

27. In a hydraulic elevator, the combination with a plunger and a car, of means for controlling the movement of the same, a brake for

the plunger, and manual means for applying and releasing said brake.

28. In a hydraulic elevator, the combination with a plunger and a car, of a cylinder for the plunger, a valve for controlling the movements of the plunger in the cylinder, a brake for the plunger, and means connected to said valve for applying and releasing said brake.

29. In a hydraulic elevator, the combination with a plunger and a car, of a cylinder for said plunger, a reversing-valve for controlling the movements of said plunger and car, a pilot-valve for controlling said main valve, a brake for the plunger, means connected to said reversing-valve for applying and releasing said brake-applying means, and means actuated from the car for operating said pilot-valve.

30. In a hydraulic elevator, the combination with a plunger and a car, of pivoted braking-jaws for said plunger, a resilient means for applying said braking-jaws to the plunger, a cam arranged to coact with said jaws to release the same, and means for actuating said cam.

31. In a hydraulic elevator, the combination with a plunger and a car attached thereto, of means for controlling the movements of the car and plunger, pivoted braking-jaws for the plunger, means for applying and releasing said jaws, means for operating said controlling means and brake-applying means, and a single device for actuating said operating means.

32. In a hydraulic elevator, the combination with a car and a plunger, of a counterweight, a brake for the counterweight, a brake for the plunger, means for operating said brakes, and a single device for actuating said operating means.

33. In a hydraulic elevator, the combination with a car, of a plunger attached thereto, a counterweight, a brake for the counterweight, an additional brake for the plunger, individual applying means for said brakes, means for operating both of said applying means, and a single means on the car for actuating said operating means.

34. In a hydraulic elevator, the combination with a car and plunger, of a counterweight connected to the car, guides for said counterweight, a brake on the counterweight arranged to coact with said guides, a resilient means for normally holding said brake in releasing position, means actuated from the car for operating said brake to apply the same, and a resilient means on the car connected to said brake-operating means for counteracting the resilient means on the counterweight to hold the brake-operating means in normal position.

35. In a hydraulic elevator, the combination with a car, of a plunger attached thereto, a counterweight connected to the car, guides for the counterweight, brake-shoes on the counterweight to be applied to said guides, a toggle for operating said brake-shoes, a spring connecting the counterweight and toggle-joint for holding the brake-shoes in releasing position, means actuated from the car for operating said toggle to apply said brake-shoes, and a spring to counteract the spring on the counterweight to hold the toggle-operating means in normal position.

36. In a hydraulic elevator, the combination with a car and its plunger, of a counterweight, means for controlling the movements of the car and plunger, a retarding device for the counterweight, a retarding device for the plunger, means for operating said controlling means and actuating means, and a single means for actuating said operating means.

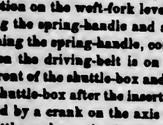
37. In a hydraulic elevator, the combination with a car, of a plunger attached thereto, a counterweight connected to the car, a cylinder for the plunger, a reversing-valve for controlling said plunger, a brake for the counterweight, an additional brake for the plunger, means for operating said reversing-valve and brakes, and mechanism on the car for actuating said operating means.

38. In a hydraulic elevator, the combination with a car and a plunger attached thereto, of a counterweight connected to the car, a cylinder for the plunger, a main valve for controlling said plunger, a pilot-valve for controlling said main valve, brakes for the counterweight and plunger, individual means for applying the same, and means controlled from the car to effect the starting or stopping of the car and the release or application of said brakes.

810,405. BRAKE-SHOE. JOSEPH D. GALLAGHER, Clearidge, N. J. Filed Nov. 6, 1902. Serial No. 129,171.

Claim.—1. A brake-shoe divided into two independent parts having adjacent surfaces extending through the shoe longitudinally between the back and face, and means for attaching the two parts together, substantially as described.

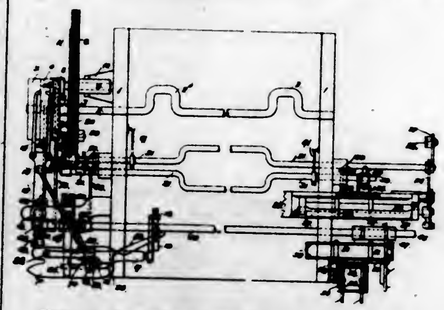
2. A brake-shoe divided into two independent parts having adjacent surfaces extending through the shoe longitudinally parallel with the face of the shoe, and means for attaching the two parts together, substantially as described.



3. A brake-shoe divided into two independent parts having adjacent surfaces extending through the shoe longitudinally parallel with the face of the shoe, the lower part having its back and face parallel with each other, and means for attaching the two parts together, substantially as described.

4. In a brake-shoe of the class described, the combination of a holding back portion provided with a dovetail on the front portion thereof, a wearing-block provided with a dovetail groove on the rear portion to engage with the holding back portion and a dovetail slide on the opposite side with which a partly-worn wearing-block may be engaged, substantially as described.

810,406. WEFT-REPLENISHING MECHANISM FOR LOOMS. JAMES M. GEST, Burnley, England. Filed Sept. 4, 1903. Serial No. 171,987.



Claim.—1. In combination, an arrangement of three pulleys on the crank-shaft, one a fast driving-pulley, the second a loose pulley and the third a loose driving-pulley combined with a pinion, a combined spur-wheel and hollow cam geared to the pinion of the loose driving-pulley, connections from the weft-fork which on the failure of weft, move the spring-handle, and connections from the spring-handle to the strap-fork for shifting the driving-belt onto the loose driving-pulley, a projection on the weft-fork lever forming an additional notch for latching the spring-handle and a projection on the weft-fork lever for latching the spring-handle, connections operated by the hollow cam when the driving-belt is on the loose driving-pulley for opening the front of the shuttle-box and ejecting the spent shuttle and closing the shuttle-box after the insertion of a fresh shuttle, connections operated by a crank on the axis of the hollow cam for inserting a fresh shuttle, and a projecting bowl on the cam spur-wheel for moving the spring-handle and setting on the loom, all substantially as herein set forth.

2. The improved motion for opening the front of the shuttle-box and ejecting the spent shuttle, consisting of the loose driving-pulley, its pinion, the large spur-wheel and the hollow cam combined therewith, the rocking shafts and their arms, the lever for opening the front plate of the shuttle-box, the boat lever for ejecting the shuttle through the open front and springs for closing the shuttle-box and returning the parts to their normal positions after a fresh shuttle has been inserted, all substantially as herein set forth.

3. The improved motion for inserting a fresh shuttle after the front of the shuttle-box has been opened and the spent shuttle ejected, consisting of a loose driving-pulley, its pinion, the large spur-wheel and the hollow cam combined, a shuttle carrier or pusher, a crank on the axis of the combined large spur-wheel and hollow cam, a spring-lever and rock-shaft, operatively connecting the carrier with the crank, the shuttle-carrier having fingers which take the bottom shuttle from the magazine and insert it into the shuttle-box the bottom of which is grooved to receive the fingers and allow the shuttle to rest on the box-bottom, all substantially as herein set forth.

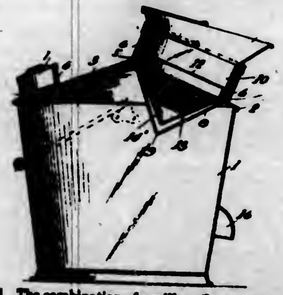
4. The combination with the magazine 36 and the improved motion for inserting a fresh shuttle after the front of the shuttle-box has been opened and the spent shuttle ejected, consisting of a loose driving-pulley, its pinion, the large spur-wheel and the hollow cam combined, a shuttle carrier or pusher 50 fingers 51 thereon, a crank on the axis of the combined large spur-wheel and hollow cam, a spring-lever and rock-shaft, operatively connecting the crank with the carrier or pusher spring-rods 55 mounted to slide in the frame 54, follow up the carrier or pusher and temporarily support the shuttles in the magazine 52 while the fingers 51 are inserting a fresh shuttle into the open shuttle-box, all substantially as herein set forth.

810,407. ABDOMINAL SUPPORTER. NUMA GROUX, St. Louis, Mo. Filed Nov. 30, 1904. Serial No. 234,013.

Claim.—1. A supporter comprising a band having narrow end portions, one of which is provided with a longitudinal slit to receive the other end portion when the supporter is positioned, and holding-straps secured to the front portion of the supporter and constituting keepers to receive the terminals of the end portions.

2. A supporter comprising a band having narrow end portions, one of which is longitudinally slitted to receive the other end portion when the supporter is positioned, holding-straps secured to the front of the supporter and constituting keepers to receive the terminals of the end portions, and buckles secured to the lower edges of the end portions and adapted to be engaged by the holding-straps.

810,408. MILK PAIL AND STRAINER. ADOLPH T. GUNDERSON, Dunbar, Iowa. Filed Nov. 8, 1905. Serial No. 286,426.



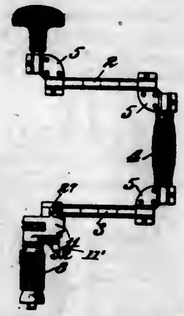
Claim.—1. The combination of a milk-pail, a safety-tube having its lower end contracted to form a small opening, a straining-tube supported by the safety-tube, a funnel-shaped receiving member at the outer end of the straining-tube, a straining-screen within the straining-tube, and a straining member secured to the inner end of said straining-tube.

2. The combination of a milk-pail having an opening therein, a safety-tube located within said opening and having its inner end contracted, a straining member supported by the safety-tube and converging to a point and a pocket located at said point and adapted to catch the solid particles intercepted by the straining members.

810,409. RATCHET-BRACE. GEORGE H. B. HEARD, Worcester, Mass. Filed July 17, 1905. Serial No. 269,994.

Claim.—1. In combination with the lower sweep-arm of a ratchet-brace, a head having a recess at its front end secured thereto, a shaft in the head having jaws on its lower end and a ratchet on its upper end extending in said recess, the rear end of said head having a central depression therein with a pair of horizontal grooves leading into said depression and on opposite sides of the latter, said rear end of the head further having vertical slots therein of considerably greater depth than said grooves, and spring-pressed plungers in the head having pins on their outer ends to engage in said slots and grooves.

2. In combination with the sweep-arms, and handle of a ratchet-brace, a head having a ratchet and jaws, a pair of spring-pressed plungers in said head, a pin carried by each plunger on the rear end thereof, said head at its rear being cut away on its under side to enable said pins to project in said cut-away part, said head being formed on its rear end with a central depression and with a pair of horizontal slots extending into said depression and being further formed with a pair of vertical slots of considerably greater depth than said horizontal slots.



3. In combination with the lower sweep-arm of a ratchet-brace, a head secured thereto and carrying a ratchet and jaws, a pair of spring-pressed plungers in said head radially disposed with respect to said ratchet and having a depression formed in the rear end of the head located between the same at their outer ends, said head at its rear end further having two pairs of cut-out portions of unequal depth, each of one pair leading into said depression, and pins carried by the plungers to engage in said cut-out portions.

4. In combination with the lower sweep-arm of a ratchet-brace, a head secured thereto and carrying a ratchet and jaws, a pair of spring-pressed plungers in the head, said head at its rear end being formed with two horizontal grooves and with a depression into which the inner end of each slot leads, said head also having a pair of vertical slots of greater depth than said horizontal grooves and a cut-out portion on its bottom into which each of said vertical slots leads, said plungers each having an outwardly-extending pin to be received in said slots and grooves, and at their outer ends project in said depression and cut-out portion.

5. In combination with the lower arm of a ratchet-brace, a head secured thereto, a shaft in the head, a ratchet on the shaft, a pair of plungers arranged in said head and disposed toward said ratchet on lines approximating the radial lines thereof, said plungers at their outer ends being spaced apart with a depression formed in the head between said plunger ends, said head further having slots leading from said plungers ends, and pins on the plungers to be received in said slots and to extend in said depression.

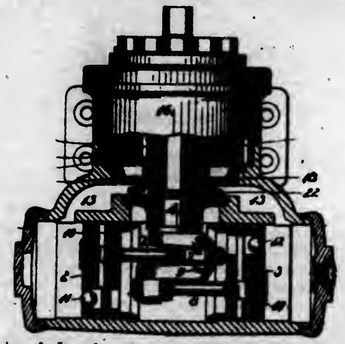
810,410. SHOW-CASE CORNER. JAMES A. HENDERSON, St. Louis, Mo. Filed Oct. 10, 1905. Serial No. 282,191.

Claim.—1. A show-case corner of the class described, comprising a right-angular member having a semicircular recess extending a part way of its length, a plurality of bosses formed integral with said member and located at intervals apart within the recess, a strip of soft material secured within said recess for supporting the edge of the glass of the show-case, and strips for retaining the glass in position substantially as specified.

2. A show-case corner of the class described, comprising a sin-

gle member for supporting the top and bottom rails of the case, a recess formed throughout the length of said member between the bottom and top rails of the case, bosses provided with threaded bores formed in said recess and integral with the member, a quarter-round strip located within the recess and secured to the member by inserting screws through said strip and into the bosses, a pair of stripe fastened to the quarter-round strip for supporting the lights of glass forming the sides and end of the case in position, substantially as specified.

810,411. DOOR CHECK AND CLOSER. WILLIAM K. HENRY, New Britain, Conn., assignor to P. & F. Corbin, New Britain, Conn., a Corporation of Connecticut. Filed May 6, 1905. Serial No. 259,661.



Claim.—1. In a door-check, a cylinder, a spindle having two cranks at its lower end, said cranks being arranged oppositely and in different planes, the lowermost crank being free-ended, the diameter of the crank-pin nearest the spindle being substantially greater than the diameter of the other crank-pin and crank, pistons, connecting-rods between said pistons and said crank-pins, the strap end of one of said connecting-rods being of sufficient diameter to freely pass over one of said crank-pins and crank-arms to engage the other crank-pin

2. In combination, a cylinder, two pistons therein, a spindle having two cranks, said cranks being arranged oppositely and in different planes, connecting-rods having strap ends, said rods adapted to said cranks and arranged between said cranks and said pistons, the strap-bearings of the crank-pins of said cranks corresponding respectively to said straps, one of said connecting-rod straps being of greater diameter than the other to slip over one of said crank-pins and cranks and properly engage the other crank, the closer mechanism including spring-chamber and spring and a liquid-tight partition between said cylinder and said spring-chamber.

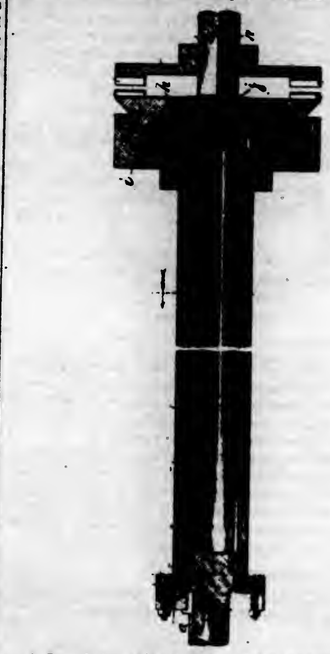
3. In a door-check, a cylinder, two pistons, a spindle having two cranks and crank-pin, oppositely arranged and in different planes, the diameter of the upper crank-pin being greater than the diameter of the other pin and crank, and connecting-rods having strap ends between said crank-pins and said pistons, the strap end of one of said rods being sufficiently large to slip over one of said cranks and crank-pin and fit the other pin.

810,412. SHAFT AND CLUTCH MECHANISM. JOHN O. HOSEA, Chicago, Ill. Filed Oct. 23, 1903. Serial No. 178,146.

Claim.—1. In a shaft and clutch mechanism, of the class described, the combination of a shaft comprising a rigid clutch portion and flexible portions, and a clutch member connected to the flexible portions of such shaft and rotatable against the tension thereof in either direction into positive contact with the rigid shaft portion, substantially as described.

2. In a shaft and clutch mechanism of the class described, the combination of a rigid shaft portion rotatably mounted, a clutch member movable into and out of positive engagement therewith, and a plurality of flexible rods extending longitudinally of and each connected at one end to such rigid shaft portion and at the other end to such movable clutch member, substantially as described.

3. In a shaft and clutch mechanism of the class described, the combination of a shaft comprising an inner core portion and rotatably mounted, a clutch member movably mounted with relation to such inner core portion, and flexible rods extending longitudinally of the inner core portion connected at one end therewith and at the other end with the movable clutch member and forming a flexible portion of such shaft, substantially as described.



4. In a shaft and clutch mechanism of the class described, the combination of a shaft comprising rigid outer tubular and inner core portions and rotatably mounted a clutch member movably mounted with relation to the rigid portion of such shaft, and flexible elements mounted between the outer tubular and inner core portions yieldingly connecting such rigid shaft portion with the movable clutch member and forming a flexible portion of the shaft, substantially as described.

5. In a shaft and clutch mechanism of the class described, the combination of a shaft provided with a rigid shaft portion rotatably mounted, a clutch member movable into and out of positive contact therewith, flexible elements yieldingly connected to such rigid shaft portion and connected to and supporting the movable clutch member, and means for connecting such movable clutch member with a driving-shaft, substantially as described.

6. In a shaft and clutch mechanism of the class described, the combination of a shaft provided with a rigid shaft portion rotatably mounted, a clutch member mounted thereon, a clutch member movable into and out of positive contact with such rigid shaft portion and its clutch member, flexible rods connected at one end with the rigid shaft portion and at the other end extending beyond the end of the rigid shaft portion and connected with such movable clutch member, and means for connecting such movable clutch member with a mechanism to be operated in connection therewith, substantially as described.

7. In a shaft and clutch mechanism of the class described, the combination of a shaft provided with a rigid portion rotatably mounted, a clutch member mounted thereon in fixed relation thereto, a clutch member movable into and out of positive contact with such rigid shaft portion and its clutch member, flexible rods connected at one end with the rigid shaft portion and at the other end with and supporting such movable clutch member, means for connecting such movable clutch member with a driving-shaft, and means mounted at the opposite end of such shaft upon which the flexible rods are mounted for operatively connecting such shaft to a mechanism to be driven thereby, substantially as described.

8. In a shaft and clutch mechanism of the class described, the combination of a shaft provided with a rigid portion rotatably mounted, a clutch member mounted upon and in fixed relation to the rigid portion of such shaft, a clutch member movable into and out of positive contact with such rigid shaft portion and its clutch member, flexible rods connected at one end with the rigid portion of such shaft and at the other end extending beyond the end of the rigid shaft portion and connected with and supporting such movable clutch member and forming the flexible portion of the flexible shaft, and means for connecting such movable clutch member with a mechanism to be operated in connection therewith, substantially as described.

9. In a shaft and clutch mechanism of the class described, the combination of a shaft provided with a rigid portion and rotatably mounted, a clutch member rigidly connected thereto and provided with an inclined friction-surface, a clutch member movably mounted with relation to such first-mentioned clutch member and having an inclined friction-surface adjacent thereto movable into and out of positive contact therewith, flexible elements yieldingly connecting such rigid shaft portion with and supporting such movable clutch member, and means for connecting such movable clutch member with a shaft to be operated in connection therewith, substantially as described.

10. In a shaft and clutch mechanism of the class described, the combination of a shaft provided with a rigid portion and rotatably mounted, a clutch member rigidly connected thereto and provided with an inclined friction-surface, a second clutch member movable into and out of positive contact therewith, a plurality of flexible rods connected at one end with the rigid shaft portion and at the other end with and supporting the movable clutch member and forming the flexible portion of such shaft, a driving-shaft, a clutch member slidingly mounted thereon movable into and out of engagement with the movable clutch member, and means for connecting the rigid portion of the flexible shaft with a mechanism to be operated in connection therewith, substantially as described.

11. In a shaft and clutch mechanism of the class described, the combination of a shaft provided with a rigid portion and having an annular core, a clutch member connected to such rigid shaft portion, a clutch member movably mounted with relation to the rigid shaft portion and core, flexible rods connected at one end to the rigid shaft portion extending along the outer surface of the core and connected at their opposite ends to such movable clutch member, and means for connecting such movable clutch member with a driving-shaft and disconnecting it therefrom, substantially as described.

12. In a shaft and clutch mechanism of the class described, the combination of a shaft provided with a rigid portion rotatably mounted and comprising an outer tubular portion and an inner core portion, a clutch member mounted upon such outer tubular portion, a clutch member movably mounted with relation to such shaft portion and its clutch member, a plurality of flexible rods attached at one end to the rigid shaft portion and at the other end to the movable clutch member and extending between the inner core and outer tubular portion of such shaft, and means for connecting such movable clutch member with a driving-shaft, substantially as described.

13. In a shaft and clutch mechanism of the class described, the combination of a shaft comprising a rigid portion and flexible rods attached to such rigid portion, and a rotatable member attached to such flexible rods and rotatable with relation to the rigid shaft portion in opposite directions against the tension of the rods into engagement with the rigid shaft portion, substantially as described.

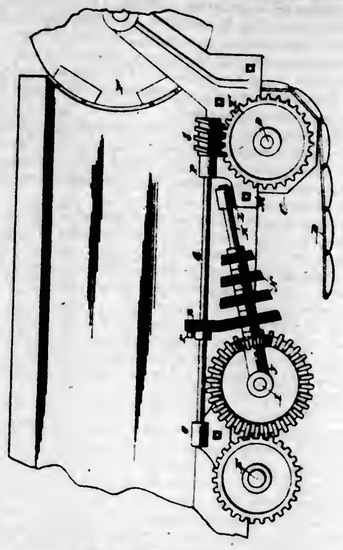
14. In a shaft and clutch mechanism of the class described, the combination of a rigid shaft portion, a plurality of normally straight flexible elastic rods each having one end secured to such rigid shaft portion in fixed relation thereto, and a movable member secured in fixed relation to the opposite ends of such flexible rods and rotatable in opposite directions with relation to the rigid shaft portion.

15. In a shaft and clutch mechanism of the class described, the combination of a rigid shaft portion, a plurality of normally straight flexible elastic rods arranged in parallel relation to each other each having one end secured to such rigid shaft portion, and a movable member secured at the opposite ends of such flexible rods and rotatable in opposite directions with relation to the rigid shaft portion.

810,413. MANURE-SPREADER. FRANK W. HOVEY, Independence, Iowa. Filed Jan. 3, 1905. Serial No. 239,317.

Claim.—The described drive mechanism for a manure-spreader, embracing, in combination with the feed-apron and its carrying-chain and sprockets, a worm-gear attached to said shaft, a worm engaging the same, a horizontal shaft for the worm, with a slidable and adjustable spur-pinion mounted thereon, an inclined shaft with differential spur-pinions mounted thereon, a bevel-pinion on said shaft, a bevel-gear engaging said bevel-pinion, a gear engaging said bevel-gear and carried by one of the traction-wheels, a casting adjacent to said gears

forming a bearing for one end of the horizontal shaft, a bearing mounted on the bevel-gear stud to take one end of the inclined shaft, and a casting having horizontal and inclined bearings for the corresponding shafts at one end, all substantially as described.



810,414. BOX-COVERING MACHINE. HARRY A. INMAN, Amsterdam, N. Y. Filed Mar. 30, 1904. Serial No. 201,713.

Claim.—1. The combination of a box-form, exterior and interior compressing-plates, means for slidably supporting the plates in line with the box-form, means for moving the plates toward and from the box-form, turning-in wings and means for yieldingly supporting said wings in the line of movement of the compressing-plates, for the purposes set forth.

2. The combination of a box-form, exterior and interior compressing-plates, means for slidably supporting the plates in line with the box-form, means for moving the plates toward and from the box-form, pivoted turning-in wings and means to close them inwardly during their movement toward the box-form, for the purposes set forth.

3. The combination of a box-form, rigid interior compressing-plates and elastic exterior compressing-plates, means for slidably supporting the compressing-plates in line with the box-form, means for moving said plates toward and from the box-form, and turning-in wings in the line of movement of said compressing-plates, for the purposes set forth.

4. The combination of a box-form, interior and exterior compressing-plates, means for slidably supporting the plates in line with the box-form, means for moving the plates to and from the box-form, and turning-in wings in the line of movement of said compressing-plates provided with springs, for the purposes set forth.

5. The combination of a shaft, a box-form on the shaft, interior and exterior compressing-plates also mounted upon said shaft and rotating therewith, means for slidably supporting the compressing-plates in line with the box-form, means for moving said plates toward and from the box-form, and turning-in wings in the line of movement of the compressing-plates, for the purposes set forth.

6. The combination of a shaft, a box-form mounted thereon, a

block adapted to longitudinal movement upon the shaft and rotary movement thereon, exterior and interior compressing-plates supported on said block, means to move the block toward and from the box-form, and turning-in wings in the line of movement of the compressing-plates, for the purposes set forth.

7. The combination of a box-form, adjustable interior and elastic exterior compressing-plates, means for moving said plates, means for slidably supporting said plates in line with the box-form, movable turning-in wings and means to move them into engagement with the projecting edges of the covering-paper and to carry them inwardly, for the purposes set forth.

8. The combination of a box-form, interior and exterior compressing-plates, means for moving said plates, means for slidably supporting said plates in line with the box-form, and pivoted turning-in wings arranged to close and move within the interior compressing-plates, for the purposes set forth.

9. The combination of a box-form, pivoted turning-in wings, springs arranged to project the wings outwardly and rearwardly away from the box-form, movable exterior and interior compressing-plates arranged to make contact with and close the turning-in wings, and means to slide said compressing-plates toward and from the box-form, for the purposes set forth.

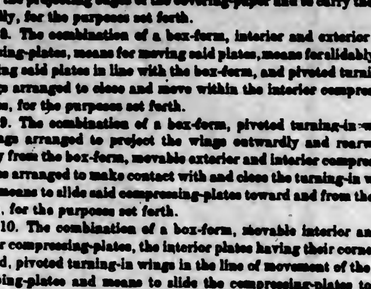
10. The combination of a box-form, movable interior and exterior compressing-plates, the interior plates having their corners reduced, pivoted turning-in wings in the line of movement of the compressing-plates and means to slide the compressing-plates toward and from the box-form, for the purposes set forth.

11. The combination of a box-form, interior compressing-plates the corners whereof are reduced, exterior elastic and adjustable compressing-plates, said compressing-plates being all arranged approximately in line with the edge of the box or cover, and turning-in wings constructed and arranged to turn in the projecting edges of the covering-paper before the compressing-plates act upon them, and means to move the compressing-plates toward and from the box-form and to operate the turning-in wings, for the purposes set forth.

12. The combination of a box-form, turning-in wings constructed and arranged to engage the projecting edges of the covering-paper and turn them inwardly, interior and exterior compressing-plates, means to move them toward and from the box-form, means for pressing the interior compressing-plates outwardly as they approach the limit of their forward movement and devices on the exterior compressing-plates to resist the outward pressure of the interior compressing-plates, for the purposes set forth.

13. The combination of a box-form, turning-in wings constructed and arranged to engage the projecting edges of the covering-paper and turn them inwardly, interior compressing-plates and elastic exterior compressing-plates, means to slide said compressing-plates toward and from the box-form and means to press outwardly the interior compressing-plates as they approach the limit of their forward movement, for the purposes set forth.

810,415. METAL LOCKER. RICHARD W. JEFFERIS, Camden, N. J., assignor to Merritt & Company, a Corporation of Pennsylvania. Filed Apr. 20, 1904. Serial No. 204,422.



Claim.—1. In a metal locker, the combination with the side panels consisting of metal frames, and a base-frame formed of angle-irons, of supporting-pieces carried by the lower irons of the side panels and depending therefrom and having lateral supports upon which the lower edges of the vertical flanges of the base-frame rest when the side panels and base-frame are assembled.

2. In a series of metal lockers, the combination of side panels consisting of metal frames, base-supporting pieces of inverted-T shape carried by the lower irons of the side-panel frames, and base-frames composed of angle-irons supported by said supporting-pieces on each side.

3. In a metal locker, the combination with the side panels consisting of metal frames, and a base-frame formed of angle-irons, of supporting-pieces carried by the lower irons of the side panels and depending therefrom and having lateral supports upon which the lower edges of the vertical flanges of the base-frame rest when the side panels and base-frame are assembled, and fastening devices to secure said vertical flanges of the base-frame to said supports.

4. In a metal locker, the combination of side panels consisting of metal frames, the vertical iron at one side being extended to form a foot, a front and rear base-supporting piece carried by the lower irons of the side-panel frames, a foot-piece carried by one of said base-supporting pieces, and a base-frame composed of angle-irons supported on each side by said front and rear base-supporting pieces.

5. In a metal locker, the combination of side panels having metal frames, a base-supporting piece d carried by the horizontal flange of the lower iron of each side panel and provided with a lateral support d^3 and an extension d^2, and a base-frame formed of angle-iron carried by said lateral support d^3 and secured to the lateral extension d^2.

6. In a metal locker, the combination of side panels having metal frames, a base-supporting piece d carried by the horizontal flange of the lower iron of each side panel and provided on each side with a lateral support d^3 and having an extension d^2, and base-frames formed of angle-iron carried by said lateral supports d^3 on each side and secured together to the lateral extension d^2.

7. In a metal locker, the combination of side panels having metal frames, a base-supporting piece carried by the horizontal flange of the lower iron of each side panel and provided with a lateral support and a longitudinal extension below said lateral support, a foot-piece secured to said longitudinal extension, and a base-frame formed of angle-iron carried by said lateral supports.

8. In a metal locker, the combination of side panels having metal frames, and a base-frame composed of angle-irons, suspended at its sides from the lower irons of the side-panel frames, and having at its front an angle-iron g secured to the front angle-iron and adapted to form the lower door-sill of the locker.

9. In a metal locker, the combination of side panels composed of metal frames, one of said frames constituting the partition between two adjacent lockers, said frames having their top horizontal flanges provided with longitudinal grooves, and top sheets having their side edges bent and clipped into engagement with said grooves to form the tops of the lockers, the groove in the top of the partition-panel engaging one bent edge of two adjacent top sheets.

10. In a metal locker, the combination of side panels having metal frames, molding-castings k secured to the tops of the front irons of said frames, and an angle-iron m carried by said molding-castings and extending longitudinally the length of a row of side panels with its upper flange projecting horizontally forward.

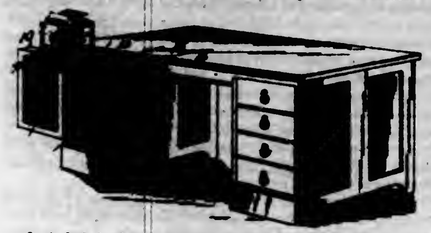
11. In a metal locker, the combination of side panels having metal frames, the top frames being provided with longitudinal grooves, an angle-iron extending longitudinally the length of a row of side panels with its upper flange projecting horizontally forward, and top sheets having their side edges bent and adapted to engage said longitudinal grooves, and their front edges bent over the forwardly-projecting edge of the longitudinal front angle-iron.

12. In a metal locker, the combination of side panels having metal frames, the top frames being provided with longitudinal grooves, an angle-iron extending longitudinally the length of a row of side panels with its upper flange projecting horizontally forward, top sheets having their side edges bent and adapted to engage said longitudinal grooves and their front edges bent over the forwardly-projecting edge of the longitudinal front angle-iron, and plates p extending over the front joints of adjacent top plates.

13. In a metal locker, the combination with the side panels consisting of metal frames carrying a sheet of reinforced metal, of the transverse shelf-supporting strips n' n' carried by the metal frames, a shelf having its side edges bent and adapted to engage said strips, and provided with flaps n^3 adapted to be bent under said strips to secure the shelf thereto.

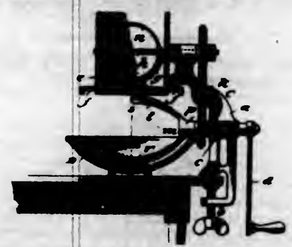
810,416. TYPE-WRITER CABINET. WILLIAM W. JOHNSTON and WILLIAM T. WARD, Brighton, Mo. Filed Apr. 28, 1905. Serial No. 257,502.

Claim.—1. A desk having a compartment and a recess provided at the upper end thereof, a leaf pivoted to swing to a position within the compartment, said leaf being adapted to move to a horizontal position and rest within the recess, and a door for the compartment having a movable section designed to normally close the recess.



2. A desk having a compartment and a recess provided at the upper end thereof, a leaf pivoted within the compartment to swing in a vertical plane, said leaf being of a form in cross-section to fit within the recess, and a door for the compartment having a movable section designed to fit and normally close the recess.

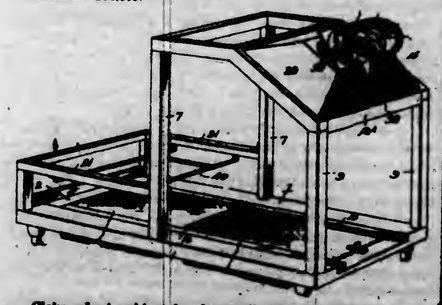
810,417. MIXER AND KNEADER. DOTTIE KARR, Powder Springs, Ga. Filed Aug. 7, 1905. Serial No. 273,694.



Claim.—1. A device for the purpose set forth, comprising a frame, lower and upper shafts journaled in the frame; said shafts being connected by gearing and one of the same being provided with means whereby it may be turned, a mixer and kneader carried by the lower shaft, a casing fixed to the frame in position to receive the upper shaft and containing a sieve, an agitator fixed to the upper shaft and arranged in the casing above the sieve, and horizontal imperforate doors guided in opposite walls of the casing, below the sieve, and slidable toward and from each other and also toward and from the vertical center of the casing.

2. In a device for the purpose set forth, the combination of a frame, a horizontal shaft journaled therein, and a mixer and kneader comprising an arm fixed to the shaft and curved outwardly in the direction of its length and movable around a horizontal center, and an arm approximately half so long as the first-mentioned arm, fixed to the shaft diametrically opposite the first-mentioned arm and curved outwardly in the direction of its length and movable around the said horizontal center.

810,418. DEVELOPING-CABINET FOR PHOTOGRAPHIC PURPOSES. BRADFORD C. KEEFER, Denver, Colo. Filed Apr. 17, 1905. Serial No. 256,009.



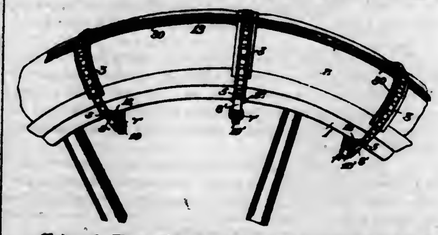
Claim.—1. A cabinet for the purpose described, comprising a frame, composed of horizontal side strips having slideways on their inner edges, and provided centrally and at one end with mortises, said strips being connected centrally and at the ends by cross-strips; upright posts having tenons which enter the mortises of said horizontal strips; a frame upon the top of said posts, the front portion of which inclines; a cap upon the inclined portion of the frame, having sight-openings and a shutter for normally closing said openings; a frame hinged near the lower ends of the rear posts, which extends to the ends of and rests upon the horizontal strips; sliding lids in said slideways; trays in said frame beneath said lids; and a light-proof cover for said frame, having sleeves at the sides thereof and a window of colored glass.

2. A cabinet for the purpose specified, comprising a horizontal platform, having rectangular, tray-supporting openings; and trays in said openings; sliding covers above said trays; upright posts at the center and at one end of said platform; a frame upon the top of said posts, the forward portion of which is at an incline; strips secured near the bottom of said center posts and extending to the rear end of the platform, and uprights for supporting the rear ends thereof; a light-proof cover for the frame thus formed, which conforms to the outline thereof, and thereby forms two chambers of unequal height; a colored-glass window in one end of the taller chamber; hand-receiving sleeves upon the sides of said cover, and a cap upon the inclined portion of the said top frame, having sight-openings, and a spring-controlled shutter for normally closing said openings.

3. A cabinet for the purpose described, comprising two light-proof chambers of unequal height, the larger of which is provided with hand-receiving openings in its sides, a sight-opening in its top and a colored-glass window in its end adjoining the smaller chamber, and a tray in the bottom of each chamber, and a sliding cover over each tray.

4. A cabinet for the purpose described, comprising two light-proof chambers of unequal height, the smaller of which is hinged to the larger chamber, a tray in the bottom of each chamber, and a sliding cover over each tray, and having the larger chamber of the two provided with a colored-glass window in its end adjoining the smaller chamber, and positioned above the smaller chamber and also provided with hand-openings in its sides and with a sight-opening in its top.

810,419. ATTACHMENT FOR VEHICLE-WHEELS. GEORGE W. KIRKPATRICK, Rochester, N. Y. Filed Feb. 3, 1904. Serial No. 191,906.



Claim.—1. The combination with a vehicle-wheel of a flexible band extending over the face of the tire, a device separate from the band and engaging the ends thereof and means for moving it relatively to the rim to tighten the band.

2. The combination with a vehicle-wheel, of a band extending over the tire, a yoke having the arms extending over the rim and detachably engaging the band and means for moving the yoke relatively to the wheel-rim.

3. The combination with a vehicle-wheel of a band extending over the tire, a yoke having spring-arms attached to the ends of the band adapted to engage opposite sides of the rim and means for moving the yoke relatively to the rim.

4. The combination with a vehicle-wheel, of a band extending over the tire, a yoke having arms detachably engaging the ends of the band and a bolt passing through the yoke and engaging the rim.

5. The combination with a vehicle-wheel embodying a rim or felly and a tire, of a band extending over the tire and a yoke having spring-arms adapted to engage opposite sides of the rim or felly, hooks on said arms adapted to receive the ends of said band and a bolt engaging the rim for moving the yoke relatively thereto.

6. The combination with a wheel, embodying a rim or felly and a tire thereon, of a band surrounding the tire, a yoke having spring-arms adapted to receive the ends of the band, projections on the arms cooperating with the band to move the arms relatively toward each other and means for moving the yoke to clamp the band to the tire.

7. The combination with a wheel embodying a rim having a tire thereon and a plurality of chain-bands extending over the tire, of means for securing them in position and chains extending between the bands and arranged over the tread portion of the tire.

810,420. ATTACHMENT FOR VEHICLE-WHEELS. GEORGE W. KREPATSKI, Rochester, N. Y. Filed Aug. 6, 1904. Serial No. 219,861.

Claim.—1. An attachment for vehicle-wheels embodying a member forming a saddle adapted to be located within the wheel-rim, means for securing the saddle thereto and a band extending over the tread portion of the wheel, means for detachably connecting one end of the band to the saddle and a securing member engaging the opposite end of the band and adjustable on the saddle to tighten the band.

2. An attachment for vehicle-wheels embodying a member forming a saddle adapted to rest upon the inner surface of the wheel-rim, and means for securing the saddle thereon, a flexible band extending over the tread portion of the wheel and members detachably engaging the ends of the band and adjustable on the saddle to tighten the band.

3. An attachment for vehicle-wheels embodying a member forming a saddle adapted to be located within the wheel-rim, having laterally-extending ears and means for securing the saddle to the rim, a band extending over the tread portion of the wheel, a fastening member attached to one of the ears on the saddle and connected to one end of the band, a bolt extending through the other ear and detachably connected to the other end of the band and a nut on the bolt for adjusting it.

4. An attachment for vehicle-wheels embodying a member forming a saddle adapted to be located within the wheel-rim, a band composed of chain-links extending over the tread portion of the wheel and attached at one end to the saddle, a bolt adjustable through the latter and provided with a hook adapted to detachably engage the free end of the band.

5. The combination with a vehicle-wheel having a rim or felly and a tire thereon, a saddle adapted to rest upon the rim and comprising sections adjustable relatively into engagement with the sides of the rim or felly, of a band extending over the tire and means adjustable on the saddle for tightening the band.

6. The combination with a vehicle-wheel having a rim or felly and a tire thereon, a saddle adapted to rest upon the rim and comprising sections adapted to rest upon the inner surface of the rim and extend over the sides thereof, means for adjusting the sections relatively, of a band extending over the tire and means adjustable on the saddle for tightening the band.

7. The combination with a vehicle-wheel having a rim or felly and a tire thereon, a saddle adapted to rest upon the rim and comprising sections adapted to rest upon the inner surface of the rim and extend over the sides thereof, and perforated ears extending outwardly on the sections, of means for adjusting the sections relatively, a band extending over the tire, securing devices connected to the ends of the band and extending through the ears and means for adjusting the devices to tighten the band.

8. An attachment for vehicle-wheels comprising a band adapted to engage over a tire composed of a plurality of pivoted links, bearing-plates arranged between the latter and the tire, wear-plates on the outer faces of the links, means for attaching said plates to the links and means for securing the band to the tire.

9. An attachment for vehicle-wheels comprising a band adapted to extend over a tire composed of a plurality of flat open links, bearing-plates arranged between the latter and the tire having upturned or rounded ends at the edges of the links, wear-plates on the outer faces of the links and fastening devices securing said plates to the separate links and means for securing the band to the tire.

10. An attachment for vehicle-wheels comprising a band adapted to extend over a tire composed of a plurality of pivoted links, bearing-plates arranged between the latter and the tire, wear-plates on the outer faces of the links, a rivet passing through the wear-plate having a shoulder engaging the bearing-plate and provided with heads securing both of said plates to the separate links and means for securing the band to the tire.

11. An attachment for vehicle-wheels comprising a band adapted to extend over a tire composed of a plurality of flat open links, bearing-plates arranged between the latter and the tire having upturned or rounded ends embracing the edges of the links, wear-plates on the outer faces of the links having ribs extending transversely thereof and means for connecting the band to the tire.

12. An attachment for vehicle-wheels comprising a band adapted to extend over a tire composed of a plurality of flat open links, bearing-plates arranged between the latter and the tire having their inner faces concaved to fit the surface of the tire, wear-plates on the outer faces of the links provided with projections extending between the sides of the links, devices securing said plates to their respective links and means for securing the band to the tire.

13. An attachment for vehicle-wheels embodying a band or cincture composed of a plurality of jointed sections extending transversely of the tire of the wheel, a lining composed of a plurality of sections, one of said sections being attached to the inner side of each of the sections of the band and means for securing the latter to the tire.

810,421. HAT-DISPLAY RACK. CHARLES KOEHLER, Toledo, Ohio. Filed Apr. 24, 1905. Serial No. 257,116.

Claim.—1. A hat-display rack, comprising a substantially U-shaped member having resilient arms and its lower connecting portion formed with an inwardly-projecting tongue, and a clamping member adjustably secured to said tongue for engaging a supporting element.

2. A hat-display rack, comprising a substantially U-shaped member formed of resilient material and having its arm-terminals bent outwardly upon themselves and formed centrally at their lower connecting portion with a reëntrant tongue, and an adjustable support-clamping member secured to said tongue.

3. A hat-display rack, comprising a substantially U-shaped member having resilient arms disposed in slightly-converging relation and each terminating in an outwardly and rearwardly bent portion and formed centrally of its arm-connecting portion with a reëntrant tongue, and a support-clamping member secured to said tongue.

4. A hat-display rack, comprising a substantially U-shaped member having resilient arms disposed in slightly-converging relation each terminating in an outwardly-extending portion and formed centrally of its arm-connecting portion with a reëntrant tongue, said tongue having its free end forked, and a support-clamping member adjustably secured within the fork of said tongue.

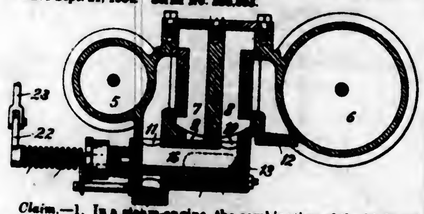
5. A hat-display rack, comprising a substantially U-shaped member having its arms terminating in outwardly-bent portions and formed centrally thereof with a reëntrant tongue, support-clamping means secured to said tongue, and tips and bands of rubber or the like secured to the points of said member having contact with a hat.

6. A hat-display rack, comprising the two correspondingly-shaped resilient arms A, A, secured together in reverse positions to form a substantially U-shaped member having a reëntrant portion, and a support-clamping member adjustably secured to said reëntrant portion.

7. A hat-display rack, comprising a stand, a clamp for engaging said stand, a resilient arm pivotally secured to each side of said clamp thence extending rearwardly in parallelism a short distance, thence changing and extending outwardly and forwardly in opposite directions and terminating in abutments adapted to press against the inner walls of a hat.

8. A hat-display rack, comprising a substantially U-shaped member having its arms terminating in abutments adapted to press against the inner walls of a hat and formed centrally of the connecting portions with a reëntrant tongue, a support-clamping member secured to said tongue, rubber tips on the terminal abutments of said arms, and rubber bands on the lower portions of said arms having their outer surface formed with projections.

810,422. ENGINE-VALVE. GEORGE LANE, Poughkeepsie, N. Y. Filed Sept. 21, 1904. Serial No. 225,362.



Claim.—1. In a steam-engine, the combination of the high and the low pressure cylinders and slide-valves therefor, a single rotary valve cooperating therewith, automatic means for moving said valve to one position, and manual means for moving said valve to a second position.

2. In combination with the high and low pressure cylinders of a steam-engine and their valve-chests, a casing having a port communicating with the high-pressure exhaust, ports communicating with the respective valve-chests, an exhaust-port to the atmosphere; a valve in said casing having a longitudinal passage communicating when in one position with the high-pressure exhaust and the low-pressure valve-chest, and passages which when the valve is in another position respectively communicate between the high and low pressure valve-chests and between the high-pressure exhaust and the atmosphere.

3. In a steam-engine, the combination of the high and low pressure cylinders, a single rotary balanced valve interposed between the cylinders and having requisite ports and passages to connect the cylinders in either direct or compound relation with the high-pressure steam, manual means for shifting the valve, and automatic means acting to return the valve to its normal position.

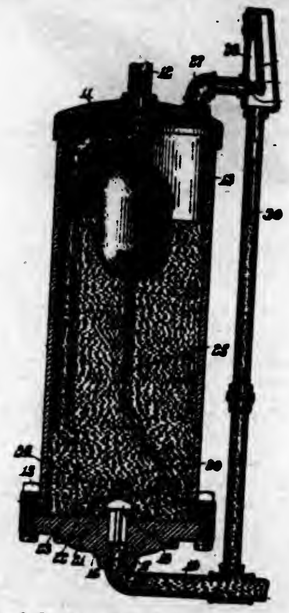
4. In a steam-engine, the combination of the high and the low pressure cylinders and slide-valves therefor, a single rotary valve cooperating therewith and having requisite ports and passages to connect the cylinders in either direct or compound relation with the high-pressure steam, a lever for moving the valve to one position and a spring for automatically moving the valve to a second position.

5. In a steam-engine, the combination of the high and the low pressure cylinders, slide-valves therefor, a single rotary valve cooperating with the slide-valve for changing the engine from compound to direct acting, together with means for manually actuating the rotary valve to make such change and automatically restoring said valve to its original position.

6. In combination with the high and low pressure cylinders of a steam-engine and their valve-chests, a casing attached thereto having a cylindrical interior and ports communicating respectively with the high-pressure exhaust, the valve-chests, and the atmosphere; a rotary valve in said casing having passages therein, one of said passages adapted to communicate between the high-pressure exhaust and the low-pressure valve-chest, another of said passages with the high and low pressure valve-chests and the source of steam, and the third between the high-pressure exhaust and the atmosphere.

7. In combination with the high and low pressure cylinders of a steam-engine and their valve-chests, a casing attached thereto and having a cylindrical interior with ports respectively communicating with the high-pressure exhaust, high and low pressure valve-chest and the atmosphere; a rotary valve in said casing provided with passages adapted to communicate between the high-pressure exhaust and the low-pressure cylinder, or between the source of steam and the high and low pressure valve-chests, and between the high-pressure exhaust and the atmosphere, together with means for throwing the first or second and third of said passages in said valve, into position to cause the engine to act as a compound or direct-acting engine as desired.

810,423. STEAM-TRAP. THOMAS MARSDEN, Magog, Canada. Filed Aug. 22, 1905. Serial No. 275,244.

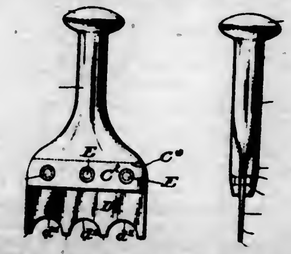


Claim.—1. In a steam-trap, the combination of a float-chamber, a float therein, an inlet, an outlet, a valve therefor operated by said float, an auxiliary outlet at the top of said float-chamber, and means for closing said auxiliary outlet under steam heat.

2. In a steam-trap, the combination of a float-chamber, a float therein, an inlet, an outlet, a valve therefor operated by said float, an auxiliary outlet at the top of said float-chamber, and a thermostat connected with said outlet and adapted to close the same under steam heat.

3. In a steam-trap, the combination of a float-chamber, a float therein, an inlet, an outlet, a valve therefor operated by said float, a discharge-pipe from said outlet, an auxiliary outlet at the top of said float-chamber and communicating with said discharge-pipe, and a thermostatic device interposed between said auxiliary outlet and said discharge-pipe and adapted to close the same.

810,424. CALKING-TOOL. THOMAS S. MASON, Camden, N. J., assignor to New York Shipbuilding Company, Camden, N. J., a Corporation of New Jersey. Filed Apr. 20, 1905. Serial No. 256,008.



Claim.—1. A calking-tool having a blade adapted to enter the seam to be calked and formed with a series of blunt projections D^4, separated by recesses d^4.

2. A calking-tool having a shank or handle C, provided with an expanded head C^3, and an elongated and slotted tool-holding portion C^2, in combination with a blade D, inserted and secured in the slotted portion C^2, and formed with a series of blunt projections D^4.

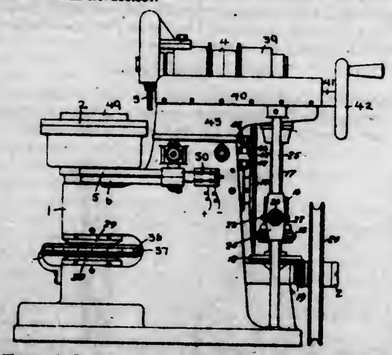
810,425. SHOE-DISPLAY FIXTURE. FRANK MINOR, Dalevia, N. Y. Filed Apr. 3, 1905. Serial No. 253,676.

Claim.—1. A shoe-display fixture comprising a shoe-supporting platform, a removable covering therefor, means for holding the removable covering on the platform, and a device projecting from the platform and through the removable covering for retaining a shoe on the platform.

2. A shoe-display fixture, comprising a shoe-supporting platform, a removable facing therefor conforming to the shape of the platform, a flanged band around the platform and overlapping the edges of the facing, and means for holding a shoe on the platform.

3. In a shoe-display fixture, the combination with a shoe-supporting platform, a pin on said platform to engage the shoe-heel and hold the shoe on the stand, an ornamental facing of the same shape as the platform, located thereon and having an opening to receive the pin, and a flanged band around the platform securing the edges of the facing.

810,426. GRINDING-MACHINE. RALPH L. MORGAN and JAMES H. HERALD, Worcester, Mass., assignors to The Heald Machine Company, Worcester, Mass., a Corporation of Massachusetts. Filed May 14, 1904. Serial No. 208,007.



Claim.—1. In a grinding-machine, the combination with a supporting-frame, of a revolving spindle journaled in said frame, a grinding-wheel carried by said spindle, means for traversing said wheel in a line coincident with its axis of rotation, a rotating spindle journaled in said frame, a work-holding bed supported on the end of said rotating spindle, and means for adjusting the plane of the axis of said grinding-wheel spindle relatively to the plane of the axis of said work-supporting spindle.

2. In a grinding-machine, the combination with a revolving grinding-wheel, of a spindle journaled in bearings at right angles to the axis of said grinding-wheel, means for rotating said spindle, a screw-threaded sleeve inclosing said spindle, a rotating hub engaging said sleeve and held from longitudinal movement, whereby said spindle is moved in a line coincident with its axis.

3. In a grinding-machine, the combination with a revolving grinding-wheel, of a spindle journaled at an angle to the axis of said grinding-wheel, a work-holding bed mounted on the upper end of said spindle, a gear attached to the lower end of said spindle, a pinion having teeth longer than the teeth of said gear, and intermediate mechanism between the driving power and said pinion.

810,427. WASHING-MACHINE. ALLAN L. OWENS, Atchison, Kans. Filed Oct. 27, 1903. Serial No. 178,709.

Claim.—1. In a washing-machine, the combination with a receptacle, lid and pounder provided with a rod working trough an aperture in the lid, a pounder-actuating mechanism comprising a substantially horizontal movable fulcrum-bar upon the lid and a lever-handle pivotally connected to said rod and fulcrum-bar respectively.

2. In a washing-machine, the combination with a receptacle, lid and pounder provided with a rod working through an aperture in the lid, a pounder-actuating mechanism comprising a substantially horizontal movable fulcrum-bar upon the lid and lever-handle pivotally and adjustably connected to said rod and fulcrum-bar respectively.

3. In a washing-machine, the combination with a receptacle, lid and pounder provided with a rod working through an aperture in the lid, a pounder-actuating mechanism, said receptacle, lid, rod and actuating mechanism being so relatively arranged and connected that the open lid is supported in a horizontal position.

4. In a washing-machine, the combination with a receptacle, lid and pounder provided with a rod working through an aperture in the lid, of a substantially horizontal movable fulcrum-bar, uprights pivoted to said bar and lid respectively, a lever-handle pivoted to the bar and rod, an elongation upon the bar and a stop-piece upon the receptacle, said elongation and stop-piece constituting engaging members for supporting through cooperation of the members correlated therewith the open lid in a horizontal position.

5. In a washing-machine, the combination with a receptacle, lid and pounder provided with a rod working through an aperture in the lid, of a pounder-actuating mechanism comprising a substantially horizontal movable fulcrum-bar, uprights independently pivoted to the lid and to the bar respectively, and a lever-handle pivotally united to the bar and to the rod respectively.

810,428. TUNNEL-SHIELD. CHARLES L. PARSELLE, Orange, N. J., and HOWARD C. WILLIAMS, Washington, D. C. Filed Jan. 3, 1905. Serial No. 239,280.

Claim.—1. The combination with a roof-shield of a plurality of supports therefor, together with means for independently advancing the supports as the excavation proceeds.

2. The combination with a roof-shield of a plurality of supports therefor, each of which sustains the entire weight of the shield and may be independently advanced as the excavation proceeds.

3. The combination with a roof-shield of a plurality of supports therefor, together with means for independently moving the said supports into and out of operative position and means for advancing the supports as the excavation proceeds.

4. The combination with a roof-shield of a plurality of supports therefor, together with means for independently raising and lowering the said supports into and out of operative position and means for advancing the supports as the excavation proceeds.

5. The combination with a roof-shield of a plurality of supports therefor, the said supports being independently advancable and provided with cooperating means whereby each during its advance is guided by the others.

6. The combination with a roof-shield of a plurality of supports therefor, each of which sustains the weight of the shield across its width and may be independently advanced as the excavation proceeds.

7. The combination with a roof-shield comprising a plurality of separately-movable sections of a plurality of supports therefor, each of which sustains the weight of the movable sections and may be independently advanced as the excavation proceeds.

8. The combination with a roof-shield of a plurality of supports therefor, each of which sustains the weight of the shield across its width and may be independently raised and lowered into and out of operative position.

9. The combination with a roof-shield comprising a plurality of separately-movable sections of a plurality of supports therefor, each of which sustains the weight of the movable sections and may be independently raised and lowered into and out of operative position.

10. The combination with a roof-shield of a plurality of supports therefor, each of which sustains the weight of the shield across its width and may be independently moved into and out of operative position and advanced as the excavation proceeds.

11. The combination with a roof-shield comprising a plurality of separately-movable sections of a plurality of supports therefor, each of which sustains the weight of the movable sections and may be independently moved into and out of operative position and advanced as the excavation proceeds.

12. The combination with a roof-shield of a plurality of supports therefor, each of which sustains the weight of the shield across its width and may be independently raised and lowered into and out of operative position and advanced as the excavation proceeds.

13. The combination with a roof-shield comprising a plurality of separately-movable sections of a plurality of supports therefor, each of which sustains the weight of the movable sections and may be independently raised and lowered into and out of operative position and advanced as the excavation proceeds.

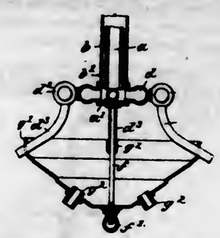
14. The combination with a roof-shield of a plurality of supports therefor, each of which sustains the weight of the shield across its width, together with means for independently raising and lowering the said supports into and out of operative position.

15. The combination with a roof-shield comprising a plurality of separately-movable sections of a plurality of supports therefor, each of which sustains the weight of the movable sections, together with means for independently raising and lowering the said supports into and out of operative position.

16. The combination with a roof-shield of a plurality of supports therefor, each of which sustains the weight of the shield across its width, together with means for independently moving the said supports into and out of operative position.

17. The combination with a roof-shield comprising a plurality of separately-movable sections of a plurality of supports therefor, each of which sustains the weight of the movable sections, together with means for independently moving the said supports into and out of operative position.

810,429. CHANDELIER. WILLIAM J. PETTIGREW, New York, N. Y. Filed Aug. 23, 1905. Serial No. 275,214.



Claim.—1. A chandelier provided with a stem, a rod depending therefrom, a cap engaging the rod, means for locking the cap to the rod, and arms foldably connected to the stem and adapted to be supported on the cap, substantially as specified.

2. A chandelier provided with a stem, a screw-rod depending therefrom, a perforated cap surrounding the rod, a nut on the rod that engages the cap, and arms foldably connected to the stem and adapted to be supported by the cap, substantially as specified.

3. A chandelier provided with a stem, a cap, means for removably securing the cap to the stem, arms foldably connected to the stem and adapted to be supported by the cap, and a shade adapted to be supported by the arms, substantially as specified.

810,430. BUNG-HOLE BUSHING. FRANK PFLUGER and EMIL CHRISTENSEN, Portland, Oreg. Filed Feb. 11, 1904. Serial No. 193,166.

Claim.—1. The combination with a stave having a counterbored bung-hole, of a bushing of ductile metal reduced in external diameter at its inner end and having flanges at both ends, the flange at the inner end conforming to the counterbore of the bung-hole, and a wrapping of packing material about the reduced portion of the bushing and confined between the shoulder formed by said reduced portion and the inner flange.

2. The combination with a stave having a counterbored bung-hole, of a bushing of ductile metal provided with an external shoulder approximately midway between its ends and having flanges at both ends, and a wrapping of packing material about the bushing between the external shoulder and the inner flange.

3. A bung-hole bushing having a flange at each end, one of the flanges being bendable, and the body of the bushing being reduced to form an exterior shoulder opposing the bendable flange, and packing surrounding said reduced portion between the said shoulder and opposing flange.

4. A bung-hole bushing having a bendable flange at one end and having its body portion reduced adjacent to said flange to form a depressed exterior packing-seat bounded by an exterior shoulder opposing the flange.

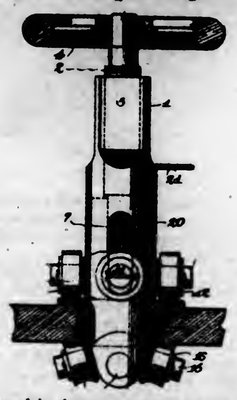
5. A bung-hole bushing having a tapered body initially flared at its inner end and reduced in external diameter adjacent to the inner end with the formation of an external shoulder intermediate of the outer and inner ends of the bushing.

810,431. COMBINED EXPANDER AND FLANGER FOR BUNG-HOLE BUSHINGS. FRANK PFLUGER and EMIL CHRISTENSEN, Portland, Oreg. Filed Feb. 20, 1904. Renewed Sept. 20, 1905. Serial No. 279,219.

Claim.—1. In a device of the character specified, a stock, means carried by the stock for applying pressure to one end of a bushing, and flanging means also carried by the stock and including an axle having rollers for engagement with the other end of the bushing, said axle being held normally in a position transverse to the stock and capable of being adjusted to a position of approximate alinement with the stock.

2. In a device of the class described, a stock, a pressure device carried by the stock and movable thereon, means for adjusting said pressure device longitudinally of the stock, and a flanger including

an axle carried by the stock and provided with rollers for engagement with the inner end of a bushing, said axle being disposed transversely of the stock during the operation of the device and capable of being adjusted into approximate alinement with the stock to permit of the device being inserted through a bushing.



3. In a device of the character specified, a longitudinally-slotted stock, a pressure device disposed transversely of said stock in said slot, means for adjusting said pressure device longitudinally of the stock, and a flanger also carried by said stock in the slot thereof and held normally in a position transverse to the stock, said flanger being adjustable into approximate alinement with the stock.

4. In a device of the class described, a stock, a feed-screw threaded in said stock, a pressure device mounted to move longitudinally upon the stock and engaged with the feed-screw for movement therewith, and a flanger carried by the stock independently of the feed-screw for engagement with the inner end of a bushing.

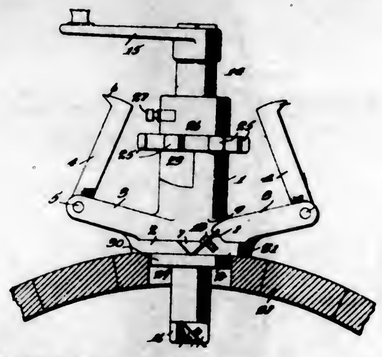
5. In a device of the class described, the combination with a rotatable longitudinally-slotted stock having a bore intersecting the outer end of the slot, and provided with a threaded portion of a presser member adjustable longitudinally within the slot and projected at opposite sides thereof externally of the stock for engagement with one end of the bushing, a screw-threaded adjusting device fitted in the bore of the stock and engaging the screw-threaded portion thereof for controlling the presser device, and a flanger member carried by the stock with the presser member located between the flanger and the screw-threaded adjusting means.

6. In a device of the class described, the combination of a rotatable longitudinally-slotted stock having one edge of the slot enlarged, a flanger pivoted within the slot and capable of being tilted into substantial alinement with the stock, an adjusting device slidable in the enlarged edge of the slot with one end connected to the flanger and its opposite end provided with an outwardly-directed handle, a presser member slidable within the slot with its opposite ends projecting externally of the stock, and means carried by the stock for adjusting the presser member therein to draw said member and the flanger into engagement with the opposite end of a bushing.

7. In a device of the class described, the combination of a rotatable stock which is bifurcated at one end and provided at its opposite end with a longitudinal bore intersecting the back of the bifurcation and having a threaded portion, one edge of the bifurcation being enlarged to form a channel, an axle pivoted within and adjacent the open end of the bifurcation and provided with terminal flanger-rollers, another axle slidable within the bifurcation and projected externally at opposite sides of the stock, rollers carried by the projected ends of said axle, a longitudinally-slotted controlling device slidable in the channel of the stock with its slot receiving the adjacent projected end of the slidable axle, one end of the controlling device being connected to the pivoted axle and its opposite end being formed into an outwardly-directed handle, and an adjusting-screw fitted in the screw-threaded bore of the stock in operative relation with the slidable axle.

810,482. COUNTERBORING-TOOL FOR CASKS. FRANK PHILBRICK and HARRY CHRISTENSEN, Portland, Oreg. Filed June 16, 1904. Serial No. 212,605.

Claim.—1. A tool of the class described comprising a stock, a rotatable and endwise-movable spindle carried by the stock, a counterboring-tool carried by the spindle, and means to rotate and move the spindle endwise for a predetermined distance in a direction to actuate the counterboring-tool, said means capable of being slid in the opposite direction to quickly withdraw the counterboring-tool from the work at the limit of the endwise-operating movement of the spindle.



2. A tool of the class described comprising a stock, a rotatable and endwise-movable spindle carried by the stock, a counterboring-tool carried by the spindle, and means to rotate and move the spindle endwise for a predetermined distance in a direction to actuate the counterboring-tool, said spindle being free to gravitate in the opposite direction to quickly withdraw the counterboring-tool from the work at the limit of the endwise-operating movement of the spindle.

3. A tool of the class described comprising a spindle carrying a cutting element, means to rotate the spindle, and means coöperating with the spindle to force the same endwise by a certain amount of rotation and on further rotation to disengage and permit free movement of the spindle in the opposite direction.

4. A tool of the class described comprising a stock having a longitudinal bore and provided with means to lock the stock against rotation, a cam upon the stock, a rotatable and endwise-movable spindle mounted in the stock and projected at opposite ends thereof, a counterboring-blade carried by one end of the stock, a cam slidable and rotatable upon the spindle in frictional engagement with the cam on the stock, and a stop carried by the spindle to limit endwise movement of the movable cam, each cam having an abrupt shoulder for alinement with the shoulder of the other cam to permit of the spindle being quickly moved in an endwise direction to withdraw the counterboring-blade from the work.

5. A tool of the class described comprising a stock having a longitudinal bore, a fixed spiral cam upon the stock terminating at its outer end in a receding shoulder, a rotatable and endwise-movable spindle mounted in the bore of the stock and projected at opposite ends thereof, a counterboring-blade carried by one end of the spindle, a cam slidable upon the spindle in frictional engagement with the cam of the stock and provided with a spiral surface terminating at its outer end in a receding shoulder, a stop carried by the spindle to limit endwise movement of the movable cam, and means for rotating the spindle, the slidable cam capable of tripping from the fixed cam when their receding shoulders are brought into alinement.

6. A tool of the class described comprising a stock having a longitudinal bore, a fixed cam upon the stock provided with a spiral surface terminating at its upper end in a pendent shoulder, a rotatable and endwise-movable spindle mounted in the bore of the stock and projected at opposite ends thereof, a counterboring-blade carried by one end of the spindle, a cam slidable upon the spindle and provided with a spiral under face in frictional engagement with the spiral face of the fixed cam and terminating at its lower end in an upright shoulder, a stop carried by the spindle to limit upward movement of the movable cam, and means for rotating the spindle, the movable cam capable of automatically tripping from the fixed cam by gravitation when the shoulders of the two cams are brought into alinement.

7. A tool of the class described comprising a stock having a longitudinal bore, a cam upon the stock, a rotatable and endwise-movable spindle mounted in the bore of the stock and projected at opposite ends thereof, a counterboring-blade carried by one end of the spindle, a cam slidable upon the spindle and in frictional engagement with the cam of the stock, a stop adjustable longitudinally upon the spindle to limit endwise movement of the slidable cam, and means to rotate the spindle, the slidable cam capable of rotation independently of the spindle to move the same in an endwise direction by engagement of the slidable cam with the fixed cam and the stop on the spindle.

8. A tool of the class described comprising a stock having a longitudinal bore and provided with an outer spiral edge forming a cam, a rotatable and endwise-movable spindle mounted in the bore of the stock and projected at opposite ends thereof, a counterboring-blade carried by one end of the spindle, an endwise-movable sleeve mounted upon the spindle and provided with a spiral edge in frictional relation with the spiral edge of the stock and also provided with a handle for rotating the sleeve, a stop-collar adjustable longitudinally upon the spindle in the path of the slidable movement of the sleeve, and means to rotate the spindle, the sleeve being rotatable independently of the spindle to feed the latter endwise during its rotatable movement.

9. A tool of the class described comprising a tubular stock having a spiral outer edge, means carried by the stock for engagement with a cask to prevent rotation of the stock and capable of being moved out of engagement with the cask to permit rotation of the stock, a planer-blade carried by the stock, a rotatable and endwise-movable spindle projected at opposite ends of the stock, a counterboring-blade carried by one end of the spindle, an endwise-movable sleeve mounted upon the spindle and having a spiral edge in coöperative relation with the spiral edge of the stock, a stop-collar adjustable longitudinally upon the spindle to limit endwise movement of the sleeve and capable of holding the latter in locked engagement with the spiral of the stock to interlock the latter and the spindle for simultaneous rotation, and means connected to the spindle for rotating the same, the sleeve also capable of rotation independently of the spindle to feed the latter in an endwise direction.

10. A tool of the class described comprising a stock having a cask-engaging anchoring device capable of being engaged with the cask to prevent rotation of the stock and also capable of being disengaged from the cask to permit rotation of the stock, a planer-blade carried by the stock, a rotatable and endwise-shiftable spindle carried by the stock, a counterboring-blade carried by the spindle, means to rotate and feed the spindle in an endwise direction upon the stock, and means to interlock the spindle and the stock for simultaneous rotation.

11. A tool of the class described comprising a stock having a planer-blade, anchor-links pivoted to the stock and having spurs to enter a cask and anchor the stock against rotation, a rotatable and endwise-movable spindle carried by the stock, a counterboring-blade carried by the spindle, means to rotate and to feed the spindle in an endwise direction independently of the stock, and means to interlock the stock and the spindle for simultaneous rotation.

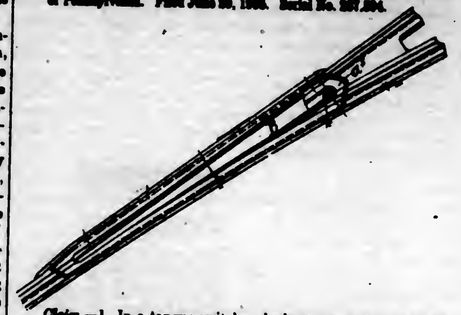
12. A tool of the class described comprising a tubular stock having a terminal annular flange provided with an opening, a concentric tubular guide-boss at the flanged end of the stock, a planer-blade fitted in the opening of the flange, substantially radial arms projected from the stock, anchor-links pivoted to the arms and provided with lateral terminal spurs, the other end of the stock having a spiral edge, a rotatable and endwise-movable spindle projected in opposite directions through the stock and provided at one end with a crank-arm, a counterboring-blade carried by the crank-arm, and endwise-movable sleeve mounted upon the spindle and provided with a spiral edge in coöperative relation with the spiral of the stock, a stop-collar adjustable longitudinally upon the spindle in the path of the sleeve and capable of holding the latter interlocked with the stock for simultaneous rotation of the latter and the spindle, and a crank to rotate the spindle, the sleeve also capable of rotation independently of the spindle to feed the latter in an endwise direction.

13. A tool of the class described comprising a stock which is capable of rotation and provided with a planer-blade, a counterboring-blade capable of adjustment to a position out of contact with the work during operation of the planer-blade, and means to bring the counterboring-blade into engagement with the work and to swing the same around the stock as a center after the completion of the operation of the planer-blade.

14. A tool of the class described including a planer-blade for the exterior of a cask, a counterboring-blade for the interior of a cask, and means to successively operate the blades.

15. A tool of the class described comprising a stock which is capable of rotation and provided with a planer-blade for operation upon the exterior of a cask, and an endwise-movable spindle mounted to rotate independently upon the stock and provided with a crank-arm carrying a counterboring-blade for operation upon the interior of a cask.

810,488. TONGUE-SWITCH. BARNEY B. PERRY, Brooklyn, N. Y., assignor to The Lorain Steel Company, Philadelphia, Pa., a Corporation of Pennsylvania. Filed June 20, 1905. Serial No. 266,304.



Claim.—1. In a tongue-switch, a body structure having a depressed floor portion forming the bed for the body portion of the tongue, and an integral overhanging portion extending forward of the tongue pin or pivot and covering the heel portion of the tongue.

2. In a tongue-switch, a body structure having a depressed tongue-bearing floor, and a raised portion overhanging the heel portion of the tongue to a point in advance of the tongue pin or pivot, said depressed and overhanging portions being integrally connected, and partially separated by an opening.

3. In a tongue-switch, the combination with a base portion, of a face-plate secured to the said base portion, said face-plate being underneath the tongue for a portion of its length, and over the tongue for the balance of its length.

4. In a tongue-switch, the combination with a base portion, of a face-plate secured thereto and forming the bed for the tongue, said face-plate having at its heel portion an integrally-connected portion which overhangs the seat for the heel portion of the tongue.

5. In a tongue-switch, the combination with a body structure having an integral portion overhanging the seat for the heel portion of the tongue, of a tongue having a heel portion shaped to enter said seat, and a pin for the tongue arranged to permit the removal of the tongue.

6. The combination of a body structure having an integral overhanging portion at the heel, a switch-tongue extending underneath said overhanging portion and having a pin or pivot, and means whereby the tongue may be removed without disturbing said overhanging portion.

7. The combination of a body structure having an overhanging portion at the heel, of a tongue having a depressed heel portion arranged to seat underneath said overhanging portion, a pin or pintle for the tongue, and means whereby the pin or pintle may be removed through the said overhanging portion.

8. In a tongue-switch of the character described, the combination with a body structure having an overhanging portion at the heel integral with the tongue-bed, of a tongue extending underneath said overhanging portion, and a pin or pivot for the tongue arranged to permit the tongue to be removed without disturbing said overhanging portion.

9. In a tongue-switch, a body structure having an integral overhanging portion at the heel extending forward of the tongue-pin and having an aperture therethrough to permit the insertion and withdrawal of the said pin.

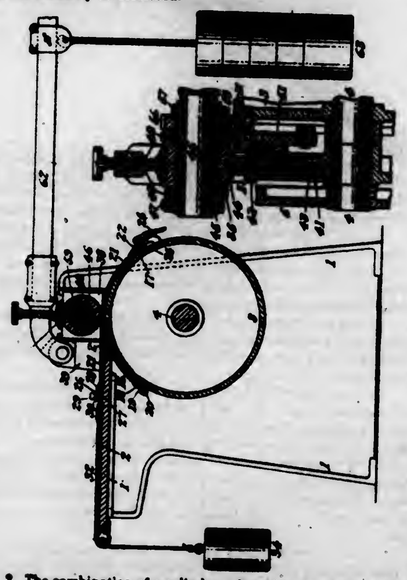
10. In a switch of the character described, the combination with a body structure having an integral overhanging portion at its heel extending forward of the tongue-pin and having an aperture therethrough to permit the insertion and withdrawal of the said pin, of a pin having means for the engagement therewith of lifting or withdrawing means.

11. The combination in a switch structure, of a body having a cavity for the reception of a tongue-pivot, a face-plate having a portion extending over the cavity and grooved for the flanges of the wheels, the said overhanging portion being integral with the facing-plate.

810,484. PHOTOMECHANICAL PRINTING. HENRY L. REED, New York, N. Y., assignor to Albert Henry Walker, trustee, New York, N. Y. Filed July 21, 1905. Serial No. 270,615.

Claim.—1. The combination of a cylinder, adapted to turn in one direction on its axis, and having an elastic cushion affixed to its

periphery, and having a flexible plate affixed on that cushion; and a metal roller, adapted to turn in the other direction on its axis, at the same surface speed as the flexible plate, and with its periphery rolling upon the surface of that plate; and a table adjacent to the cylinder, and adapted to support the rear part of that plate, at the beginning of the turning of the cylinder, and to gradually surrender that plate to the cylinder, as the cylinder turns; and a weight, attached to the rear border of the flexible plate, and subjecting to tension the forward movement thereof; and a pair of levers and weights, adapted to exert pressure on the journal-boxes of the metal roller, as it rolls; all substantially as described.



2. The combination of a cylinder, adapted to turn in one direction on its axis, and having an elastic cushion affixed to its periphery, and having a flexible plate affixed on that cushion; and a metal roller, adapted to turn in the other direction on its axis, at the same surface speed as the flexible plate, and with its periphery rolling upon the surface of that plate; and a table adjacent to the cylinder, and adapted to support the rear part of that plate at the beginning of the turning of the cylinder, and to gradually surrender that plate to the cylinder, as the cylinder turns; and a weight, attached to the rear border of the flexible plate, and subjecting to tension the forward movement thereof; all substantially as described.

3. The combination of a cylinder, adapted to turn in one direction on its axis, and having an elastic cushion affixed to its periphery, and having a flexible plate affixed on that cushion; and a metal roller, adapted to turn in the other direction on its axis, at the same surface speed as the flexible plate, and with its periphery rolling upon the surface of that plate; and a table adjacent to the cylinder, and adapted to support the rear part of that plate, at the beginning of the turning of the cylinder, and to gradually surrender that plate to the cylinder, as the cylinder turns; and a pair of levers and weights, adapted to exert pressure on the journal-boxes of the metal roller, as it rolls; all substantially as described.

4. The combination of a cylinder, adapted to turn in one direction on its axis, and having an elastic cushion affixed to its periphery, and having a flexible plate affixed on that cushion; and a metal roller adapted to turn in the other direction on its axis, at the same surface speed as the flexible plate, and with its periphery rolling upon the surface of that plate; and a weight, attached to the rear border of the flexible plate, and subjecting to tension the forward movement thereof; and a pair of levers and weights, adapted to exert pressure on the journal-boxes of the metal roller, as it rolls; all substantially as described.

5. The combination of a cylinder, adapted to turn in one direction on its axis, and having an elastic cushion affixed to its periphery, and having a flexible plate affixed on that cushion; and a metal roller, adapted to turn in the other direction on its axis, at the same surface speed as the flexible plate, and with its periphery rolling upon the surface of that plate; and a table adjacent to the cylinder, and adapted to support the rear part of that plate, at the beginning of the turning of the cylinder, and to gradually surrender that plate to the cylinder, as the cylinder turns; all substantially as described.

6. The combination of a cylinder, adapted to turn in one direction on its axis, and having an elastic cushion affixed to its periphery, and having a flexible plate affixed on that cushion, and a metal roller, adapted to turn in the other direction on its axis, at the same surface speed as the flexible plate, and with its periphery rolling upon the surface of that plate; and a table adjacent to the cylinder, and adapted to support the rear part of that plate, at the beginning of the turning of the cylinder, and to gradually surrender that plate to the cylinder, as the cylinder turns; and a weight attached to the rear border of the flexible plate, and subjecting to tension the forward movement thereof; all substantially as described.

7. The combination of a cylinder, adapted to turn in one direction on its axis, and having a flexible plate affixed on its periphery; and a metal roller, adapted to turn in the other direction on its axis, at the same surface speed as the flexible plate; and with its periphery rolling upon the surface of that plate; and a table adjacent to the cylinder, and adapted to support the rear part of that plate, at the beginning of the turning of the cylinder, and to gradually surrender that plate to the cylinder, as the cylinder turns; and a weight attached to the rear border of the flexible plate, and subjecting to tension the forward movement thereof; and a pair of weights and levers, adapted to exert pressure on the journal-boxes of the metal roller, as it rolls; all substantially as described.

8. The combination of a cylinder, adapted to turn in one direction on its axis, and having a flexible plate affixed on its periphery; and a metal roller, adapted to turn in the other direction on its axis, at the same surface speed as the flexible plate; and with its periphery rolling upon the surface of that plate; and a table adjacent to the cylinder, and adapted to support the rear part of that plate, at the beginning of the turning of the cylinder, and to gradually surrender that plate to the cylinder, as the cylinder turns; and a weight attached to the rear border of the flexible plate, and subjecting to tension the forward movement thereof; all substantially as described.

9. The combination of a cylinder, adapted to turn in one direction on its axis, and having a flexible plate affixed on its periphery; and a metal roller, adapted to turn in the other direction on its axis; at the same surface speed as the flexible plate, and with its periphery rolling upon the surface of that plate; and a table adjacent to the cylinder, and adapted to support the rear part of that plate, at the beginning of the turning of the cylinder, and to gradually surrender that plate to the cylinder, as the cylinder turns; and a pair of weights and levers, adapted to exert pressure on the journal-boxes of th metal roller, as it rolls; all substantially as described.

10. The combination of a cylinder, adapted to turn in one direction on its axis, and having a flexible plate affixed on its periphery; and a metal roller, adapted to turn in the other direction on its axis, at the same surface speed as the flexible plate; and with its periphery rolling upon the surface of that plate; and a weight attached to the rear border of the flexible plate, and subjecting to tension the forward movement thereof; and a pair of weights and levers, adapted to exert pressure on the journal-boxes of the metal roller, as it rolls; all substantially as described.

11. The combination of a cylinder, adapted to turn in one direction on its axis, and having a flexible plate affixed on its periphery; and a metal roller, adapted to turn in the other direction on its axis, at the same surface speed as the flexible plate; and with its periphery rolling upon the surface of that plate; and a table adjacent to the cylinder, and adapted to support the rear part of that plate, at the beginning of the turning of the cylinder, and to gradually surrender that plate to the cylinder, as the cylinder turns; all substantially as described.

12. The combination of a cylinder, adapted to turn in one direction on its axis, and having a flexible plate affixed on its periphery; and a metal roller, adapted to turn in the other direction on its axis, at the same surface speed as the flexible plate; and with its periphery rolling upon the surface of that plate; and a weight attached to the rear border of the flexible plate, and subjecting to tension the forward movement thereof; all substantially as described.

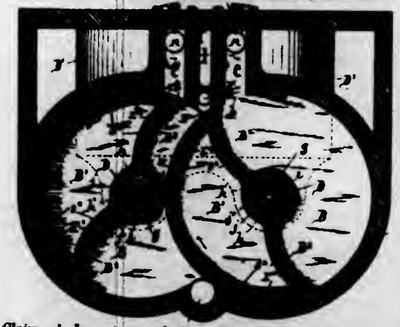
13. The combination of a carrier, having a curved carrying-surface adapted to move through an arc of a circle, and having a flexible printing-plate affixed on that surface; and a metal roller, adapted to revolve at the same surface speed as the movement of the printing-plate on the carrier, and with its periphery rolling upon the surface of that plate; and a weight attached to the rear border of the flexible plate, and subjecting to tension the forward movement thereof; all substantially as described.

14. The combination of a carrier, having a curved carrying-surface adapted to move through an arc of a circle, and having a flexible printing-plate affixed on that surface; and a metal roller, adapted to revolve at the same surface speed as the movement of the printing-plate on the carrier, and with its periphery rolling upon the surface of that plate; and a tension device attached to one border of the flexible plate, and subjecting it to tension, during the movement thereof; all substantially as described.

15. The combination of a carrier, having a curved carrying-surface adapted to move through an arc of a circle, and having a flexible inked printing-plate affixed on that surface; and a metal roller adapted to revolve at the same surface speed as the movement of the printing-plate on the carrier, and with its periphery rolling upon the inked surface of that plate, and having its circumference identical in measurement with the length of the inked surface of the printing-plate, so that one revolution of the roller upon the plate, will take ink from the entire surface of the plate, and so that the ink that taken will precisely encircle the roller; all substantially as described.

16. The combination of a carrier, having a curved carrying-surface adapted to move through the arc of a circle, and having a flexible inked intaglio gelatin printing-plate affixed on its surface; and a metal roller, adapted to revolve at the same surface speed as the movement of the printing-plate on the carrier, and with its periphery rolling upon the inked surface of that plate; and means for pressing the roller with great force upon the inked intaglio gelatin printing-plate, in order to transfer sufficient ink from the depressions in the plate to the periphery of the roller; all substantially as described.

810,435. **ROTARY EXPLOSIVE-ENGINE.** FRANK REYNOLDS, Syracuse, N. Y. Filed Nov. 2, 1903. Serial No. 179,461.



Claim.—1. In a rotary explosive-engine, the combination of a case comprising two intersecting cylindrical compartments and formed with two separate explosion-compartments each provided with a port affording communication with its respective cylindrical compartment, suitable igniters in the explosion-compartments, parallel rotary shafts extending axially through the said cylindrical compartments and geared to rotate in opposite directions, sectoral pistons in the latter compartments and secured to the respective shafts and opening and closing said ports alternately, compression-chambers communicating directly with the respective explosion-compartments, a carburetor communicating with each of said chambers alternately, means supplying the carburetor with air and gasolene, reciprocating pistons in the chambers and operated by the aforesaid shafts, and compressing the mixture in said chambers and forcing the compressed mixture into the explosion-compartments, check-valves in said chambers and explosion-compartments and opened by the suction and compression respectively of the mixture, means automatically closing said valves, and exhaust-ports in the said case, substantially as described.

2. In a rotary explosive-engine, the combination of a case comprising two intersecting cylindrical compartments and explosion-compartments each communicating with the upper portions of its respective cylindrical compartment, parallel shafts extending axially through the latter compartments and geared to rotate in opposite directions, sectoral pistons in the cylindrical compartments and secured to said shafts, suitably-controlled igniters in the explosion-compartments, a pair of upright chambers communicating at their upper portions directly with the respective explosion-compartments, a carburetor communicating with the upper portions of each of the chambers alternately, reciprocating pistons in said chambers operated by the aforesaid shafts and drawing the explosive mixture from the carburetor alternately into said chambers and compressing the mixture therein and subsequently forcing the compressed mixture from the chambers into the corresponding explosion-compartments, automatic check-valves between the latter compartments and compression-chambers and between the said chambers and carburetor, and exhaust-ports in the said case, substantially as described.

3. In a rotary explosive-engine, the combination of a case comprising two intersecting cylindrical compartments and explosion-compartments each communicating with its respective cylindrical compartment, parallel shafts extending axially through the latter compartments and geared to rotate in opposite directions, sectoral pistons in said cylindrical compartments and secured to said shafts, suitably-controlled electric sparking devices in said explosion-compartments, a pair of vertically-disposed cylindrical chambers communicating at their upper portions with the respective explosion-compartments, a carburetor communicating with the tops of said chambers, reciprocating pistons in said chambers, and operated by said shafts and alternately drawing the explosive mixture from the carburetor into the chambers and compressing the same therein and forcing the compressed mixture into the corresponding explosion-compartments, horizontally-movable check-valves in said compression-chambers opened by the suction-strokes of the latter pistons, and like valves in the explosion-compartments opened by the compression-strokes of the pistons, springs closing said valves, and means for exhausting the exploded mixture from the aforesaid cylindrical compartments substantially as described.

4. In a rotary explosive-engine, the combination of a case comprising two intersecting cylindrical compartments and explosion-compartments each communicating with its respective cylindrical compartment, parallel shafts extending axially through the latter compartments and geared to rotate in opposite directions, sectoral pistons in said cylindrical compartments and secured to said shafts, igniters in the explosion-compartments, means for alternately supplying the latter compartments with explosive mixture under compression, and suitable check-valves and exhaust-ports arranged substantially as and for the purpose set forth.

5. In a rotary explosive-engine, the combination of a case comprising two intersecting cylindrical compartments and explosion-compartments each communicating with its respective cylindrical compartment, parallel rotary shafts extending through said cylindrical compartments and geared to rotate in opposite directions, sectoral pistons secured to the respective shafts, igniters in the explosion-compartments, a pair of cylindrical chambers communicating at their upper ends with the respective explosion-compartments, a carburetor communicating with said chambers, a gasolene-chamber communicating with the carburetor, an air-inlet port and a mixture-discharge port in the carburetor, means for simultaneously opening and closing said ports, means controlling the feed of the gasolene to the carburetor, suitably-operated reciprocating pistons in the aforesaid cylindrical chambers, and drawing the explosive mixture from the carburetor alternately into said chambers and compressing the same therein and forcing the compressed mixture into said explosion-compartments, cranks and rods imparting movement from the aforesaid shafts to the latter pistons, check-valves in said explosion-compartments and compression-chambers, and exhaust-ports in said case substantially as described and shown.

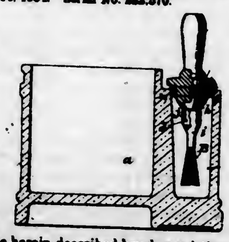
6. In a rotary explosive-engine, the combination of a case comprising two intersecting cylindrical compartments and explosion-compartments each communicating with its respective cylindrical compartments, igniters in the explosion-compartment, parallel shafts extending axially through the cylindrical compartments and geared to rotate in opposite directions, sectoral pistons in said latter compartments and secured to said shafts, exhaust-ports in said case, a pair of cylindrical compression-chambers, pipes conducting the compressed mixture from the chambers to the respective explosion-compartments, check-valves opening and closing said pipes, a carbureter, an inlet-port and a mixture-outlet port in the carbureter, a gasolene-chamber communicating with the carbureter, a supply-pipe connected to the gasolene-chamber, means for simultaneously opening and closing the aforesaid ports in the carbureter, a pipe connected to the carbureter, branch pipes leading from the latter pipe to the tops of the respective compression-chambers, reciprocating pistons in the latter chambers and actuated by the aforesaid shafts, said pistons alternately drawing the explosive mixture from the carburetor into the respective chambers and compressing the mixture therein and forcing the compressed mixture into the said explosion-compartments, and check-valves in said latter compression-chambers opening and closing the aforesaid branch pipes, substantially as described.

7. In the herein-described rotary explosive-engine the combination of a case comprising two intersecting cylindrical compartments, parallel shafts extending axially through said compartments and geared to rotate in opposite directions, said shafts each being provided with a longitudinal bore and at one end with a transverse port, chambers surrounding the respective shafts at said ends and communicating with said bores, a pipe affording communication between the chambers, hollow sectoral pistons in said compartments and formed with hubs by which they are secured to said shafts, transverse ports in the shaft extending from the aforesaid bores, and the said hubs formed with radial passages communicating with said ports and affording communication between the bores of said shafts and interiors of the pistons, as and for the purposes set forth.

8. In the herein-described rotary explosive-engine, the combination with a case formed with two cylindrical compartments, suitably-journaled sectoral pistons in said compartments, grooves formed in the end faces of said pistons, packing in said grooves, and corrugated spring-metal strips disposed back of the packing and pressing the same outward for the purpose set forth.

9. In the herein-described rotary explosive-engine, the combination of a case comprising two intersecting cylindrical compartments main explosion-compartments each communicating with its respective cylindrical compartment and a supplemental explosion-compartment communicating alternately with said cylindrical compartments, oppositely-rotating sectoral pistons journaled in the latter compartments, exhaust-ports in the case, igniters in said explosion-compartments, a main carbureter supplying the main explosion-compartments with mixture, another carbureter supplying the supplemental explosion-compartment with mixture, and a compressed-air tank or chamber communicating with the latter carbureter substantially as and for the purpose set forth.

810,436. **PASTE-JAR BRUSH.** AUGUST N. RITZ, Milwaukee, Wis. Filed Nov. 14, 1904. Serial No. 233,670.



Claim.—The herein-described brush consisting of a handle having a conical central portion formed with an inclined groove and terminating at its lower end in a pintle, a compressible gasket fitting said groove, a tabular holder having the upper portion thereof engaged by said pintle to which it is fastened, and bristles secured in the lower portion of the holder.

810,437. **CAR-WHEEL.** GEORGE D. SPRINGER and FRANK LISTER, South Knoxville, Tenn. Filed June 16, 1905. Serial No. 265,623.

Claim.—1. In a device of the class described, a wheel having a hub, said hub having its interior bearing-surface chilled or hardened, and a bushing or sleeve having its exterior surface chilled or hardened and contacting with the chilled or hardened interior surface of the hub, the hub and bushing or sleeve being relatively rotatable.

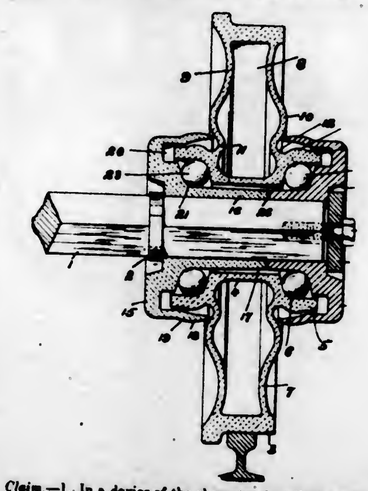
2. In a device of the class described, a wheel having a hub provided with a cylindrical opening therethrough, the interior bearing-surface of said opening being chilled or hardened, and a cylindrical bushing fitted within the said wheel and having its exterior bearing-surface chilled or hardened, said hub and bushing being relatively rotatable.

3. In a device of the class described, a wheel having a hub provided with a cylindrical opening therethrough, the interior surface of said hub being chilled or hardened, a bushing fitted within the hub and having its exterior surface chilled or hardened, an axle and means for securing the bushing to the axle to provide chilled or hardened rotating bearing-surfaces between the wheel-hub and bushing.

4. The combination of a wheel having a hub provided with a cylindrical opening therethrough, the interior surface of said hub being chilled or hardened, a cylindrical bushing, having its exterior surface chilled or hardened, and seated within said hub, an axle and a pin for securing the bushing non-rotatably to the axle to afford chilled rotating bearing-surfaces between the interior surface of the hub and exterior surface of the bushing.

5. The combination of a wheel having a hub provided with an opening therethrough, the interior surface of said hub being chilled or hardened, an inturned portion at one end of the hub, a bushing having its exterior surface chilled or hardened and seated within the opening in the hub, an axle, means for securing the bushing to the axle, and a cap secured to the wheel and extending over the end of the bushing and axle.

810,438. **TRUCK-WHEEL.** FREDERICK W. STICKLE, Waterbury, Conn., assignor of one-half to Edward W. Beach, Waterbury, Conn. Filed Apr. 18, 1904. Renewed Aug. 24, 1905. Serial No. 275,686.

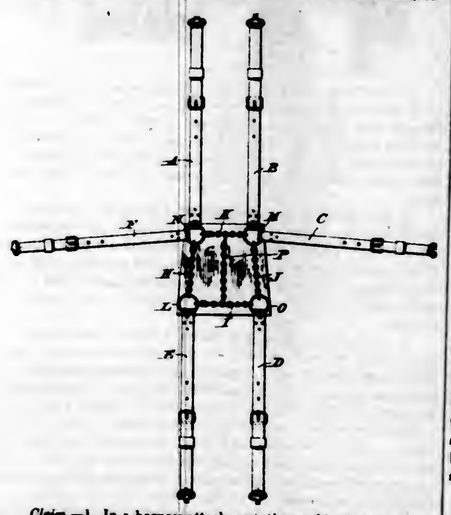


Claim.—1. In a device of the character described comprising a wheel having a web provided with outwardly-curved portions near the base thereof, a hub formed integral therewith, and bearing-collars formed integral with each end of the hub adjacent to the outwardly-curved portions of the web, non-rotatable cones mounted within the hub provided with recesses adapted to receive the ends of the bearing-collars and integral curved flanges formed on said cones adapted to overlie the bearing-collars and extending inwardly to the web to lie beneath the outwardly-curved portions thereof, and a plurality of antifriction-balls mounted between the collars and the cones, substantially as described.

2. In combination with a wheel having a hub formed integral therewith, bearing-collars provided with curved portions formed upon said hub, and a web connecting the hub with the rim provided with outwardly-curved portions overlying the bearing-collars, non-rotatable cones provided with extensions lying within the hub and having recesses formed therein to receive the ends of the bearing-collars, integral curved flanges formed thereon extending over said bearing-collars and lying adjacent to the base of the outwardly-curved portions of the web, and antifriction-balls carried between the cones and the bearing-collars, substantially as described.

3. In a device of the character set forth, a wheel comprising an integral hub web and rim, integral bearing-collars formed at each end of the hub having exterior enlarged rounded portions adjacent to the web, said web having outwardly-curved portions overlying said bearing-collars, cone members having portions extending within the hub, integral curved flanges formed upon said cone members projecting over the curved portions of the bearing-collars and lying adjacent to the web at the base of the outwardly-curved portions thereof, and antifriction-balls mounted between the cones and the bearing-collars, substantially as described.

810,439. **MINE-HARNESS.** JOSEPH P. STRATTON and ROBERT S. STRATTON, Sullivan, Ind. Filed Nov. 30, 1904. Serial No. 234,974.



Claim.—1. In a harness attachment, the combination of a flexible substantially rectangular pad, a ring at each corner of the pad, chains connecting said rings and fastened to the pad, and straps fastened to the rings and adapted to be connected with the whiffletree or traces to hold the pad in position.

2. In a harness attachment, the combination of a flexible substantially rectangular pad, a ring secured to each corner thereof, longitudinal and transverse chains superimposed on said pad and connecting said rings, a longitudinal chain connecting the centers of said transverse chains, with straps fastened to said rings and connected with the whiffletree or traces whereby the latter are supported and the pad held in position.

810,440. **SASH LOCK AND FASTENER.** FRANCIS M. STRAUSS, Boulder, Colo., assignor of one-half to Henry W. Sheets, Boulder, Colo. Filed Aug. 11, 1905. Serial No. 273,743.

Claim.—1. A window-fastener comprising in combination with a rack member adapted to be secured to the window frame or casing, of a pair of semicircular peripherally-racked sections pivotally secured to the window-sash, said sections being adapted to be independently moved into engagement with the rack and interlock therewith, and when swung together forming a circular disk, said sections having semicircular cut-away portions forming a central aperture when the sections are swung together, substantially as shown and described.

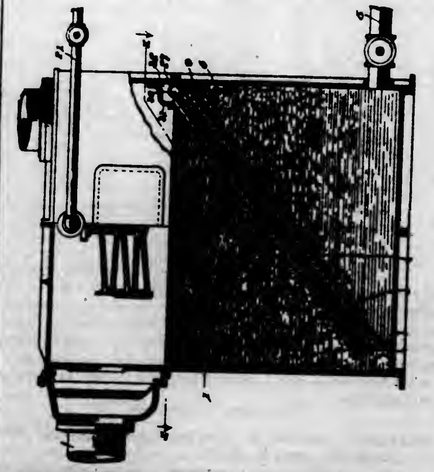
2. A window-fastener comprising in combination with a rack member adapted to be secured to the window frame or casing, of a pair of semicircular peripherally-racked sections pivotally secured to the window-sash, said sections being adapted to be independently moved into engagement with the rack and interlock therewith, and when swung together forming a circular disk, said sections having semicircular cut-away portions forming a central aperture when the sections are swung together, said semicircular sections each having a handle substantially as shown and described.

3. A sash-fastener comprising in combination with a rack securable to the window-frame, of a lock member comprising a pair of semicircular rack-sections pivotally secured to the window-frame, each section adapted to be independently thrown into engagement with the rack and a resilient washer secured between said lock member and the window-sash to hold the sections in their adjusted position, substantially as shown and described.

4. A window-fastener comprising a rack member adapted to be secured to the window frame or casing, a lock member comprising a pair of semicircular peripherally-racked members pivotally secured to the window-sash, said members adapted to be independently moved into engagement with the rack and interlock therewith, said members when swung together forming a circular disk, said members having semicircular cut-away portions forming a central aperture when the sections are swung together, and a resilient washer secured between said lock member and the sash to hold the sections in their adjusted positions, substantially as shown and described.

5. A window-fastener comprising a rack member adapted to be secured to the window frame or casing, a lock member comprising a pair of semicircular peripherally-racked members pivotally secured to the window-sash, said members adapted to be independently moved into engagement with the rack and interlock therewith, said members when swung together forming a circular disk, said members having semicircular cut-away portions forming a central aperture when the sections are swung together, and handle members for said sections, and a resilient washer secured between said lock member and the sash to hold the sections in their adjusted positions, substantially as shown and described.

810,441. **FEED-WATER HEATER.** OMAN L. STUMP, Marion, Ohio, assignor of one-third to John Reidenbaugh and one-third to Edwin D. Packard, Marion, Ohio. Filed Aug. 19, 1904. Serial No. 221,348.



Claim.—1. A feed-water heater having a steam space or chamber above and a filtering-chamber below, and a filtering-bed extending in an inclined position across said filtering-chamber to make it self-cleaning, the water inlet and outlet being respectively on the upper and under sides of said filtering-bed, substantially as described.

2. A feed-water heater having a steam space or chamber above and a filtering-chamber below, and a filtering-bed extending across

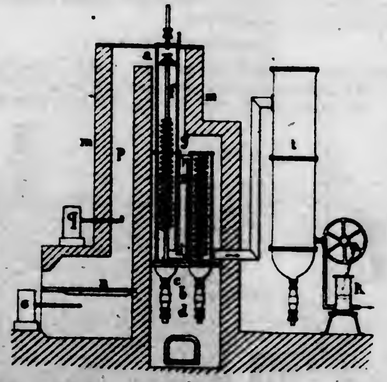
the said filtering-chamber in an inclined position from about the water-line to the bottom of the chamber to make it self-cleaning, the water inlet and outlet being respectively on the upper and under sides of said bed, substantially as described.

2. A feed-water heater having a steam-chamber above and a filtering-chamber below, an inclined filtering-bed extending across the filtering-chamber between the water inlet and outlet, its inclination making it self-cleaning, and a sediment-chamber located at the foot of the filtering-bed and provided with a sediment outlet or blow-off, substantially as described

4. A feed-water heater having a steam-chamber above and a filtering-chamber below, and a filtering-bed extending in an inclined position across said filtering-chamber between the feed-water inlet and outlet, the inclination of the bed making the same self-cleaning by the discharge of the deposit from its upper surface by gravity, the heater being provided with a wash-water conduit located at the upper end of said filtering-bed, connected with a source of supply of water under pressure, and adapted to direct the same over the filtering-bed to wash therefrom any deposit not discharged therefrom in the normal operation of the structure, substantially as described.

5. A feed-water heater having a steam-chamber above and a filtering-chamber below, and a filtering-bed extending in an inclined position across said filtering-chamber between the feed-water inlet and outlet, the inclination of the bed making the same self-cleaning by the discharge of the deposit from its upper surface by gravity, the heater being provided with a wash-water conduit located at the upper end of said filtering-bed, connected with a source of supply of water under pressure, and adapted to direct the same over the filtering-bed to wash therefrom any deposit not discharged therefrom in the normal operation of the structure, said heater being also provided with a sediment-chamber located at the foot of the filtering-bed and having a sediment outlet or blow-off, substantially as described.

810,442. PROCESS OF TREATMENT OF VINASSES. CHARLES SUSSE, Paris, France. Original application filed Dec. 30, 1902, Serial No. 137,127. Divided and this application filed Jan. 6, 1904. Renewed Nov. 7, 1905. Serial No. 286,286.

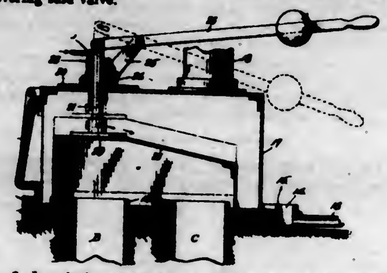


Claim.—The herein-described process of extracting from vinasses the glycerin contained therein in the form of a mixture of glycerin and water to be concentrated and for producing a residue containing all the ammonia which exudate in first rendering the vinasses acid and then causing it to flow in a vacuum along a surface heated to a maximum temperature of 205° centigrade and causing the steam produced to have a gyratory movement to free it of particles carried with it.

810,443. GAS-VALVE. JOHN SOMERSET, Johnstown, Pa. Filed June 30, 1905. Serial No. 267,772.

Claim.—1. The combination with a fixed water-cooled casing, of a plurality of passages having vertically-extended walls terminating above the lower portion of the casing, a water-sealed valve arranged within the casing and movable independently thereof, and a vertically-movable and revolvable carrying-spindle for said valve.

2. In a device of the class specified, a plate provided with a marginal flange, and a plurality of annular flanges within the marginal flange to form a water-containing vessel, a vertically-movable and revolubly-adjustable valve arranged above the plate, and having its lower edge sealed in the water, and a stationary water-sealed casing covering said valve.



3. In a device of the class specified, a plate having a marginal flange and provided with a plurality of flanges within the marginal flange to form a water-containing vessel, a valve, the lower edge of which is sealed in the water, a vertically-movable and revolvable spindle supporting the valve, an operating member connected to said spindle, and a stationary water-sealed casing surrounding said valve.

4. In a device of the class specified, a stationary water-sealed casing inclosing a plurality of ports or passages, an open-bottom valve arranged within said casing and movable independently thereof for controlling communication between the passages, a spindle connected to said valve, a lever connected to the spindle, and a revolvable support on which said lever is mounted to permit turning of the valve.

5. In a device of the class described, a flanged base arranged to form a water seal and provided with a plurality of annular flanges forming the terminals of air or gas passages, a casing extending over all of such passages and provided with a bearing, a longitudinally-movable and revolvable spindle mounted in said bearing, a valve carried by the spindle and controlling communication between the passages, a collar surrounding the bearing, bearing-balls between the collar and bearing, a bracket projecting from the collar, a weighted operating-lever mounted on the bracket, and means for connecting the lever to the spindle.

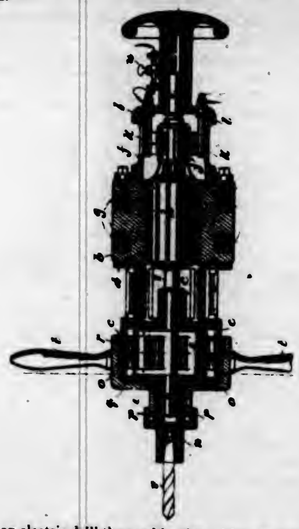
6. In a device of the class described, the combination with a base-plate having a marginal flange to form a water-containing vessel and provided at one side with an overflow-compartment from which waste water is discharged, said plate being further provided with a plurality of annular flanges arranged at the terminals of gas or air passages, a casing inclosing all of said passages, a bearing in said casing, said bearing being in vertical alinement with one of the passages, a longitudinally-movable and revolvable spindle mounted in said bearing, a valve carried by the spindle and controlling communication between the passages, said spindle being hollow and provided at the top with a water-supply connection, and at the bottom with ports for the discharge of the water, a collar surrounding the bearing, and supported by bearing-balls, a bracket projecting from the collar, and a pivotally-mounted weighted lever fulcrumed to the bracket and connected to the upper portion of the spindle.

810,444. ELECTRIC DRILL. CHARLES W. THIEL, Milwaukee, Wis., assignor of one-third to Alexis D. Sussen and one-third to John T. Sussen, Milwaukee, Wis. Filed June 1, 1903. Serial No. 159,695.

Claim.—1. In an electric drill the combination with a suitable case or frame, of a motor-armature and a rotary drill-holder mounted coaxially therein, differential internal gears, fixed one to the drill-holder and the other to said case or frame, and a crank fixed to the armature-shaft and provided with a pinion which meshes with both of said internal gears, said drill-holder being rotatable and the case stationary relatively to each other and the armature-shaft, substantially as described.

2. In an electric drill the combination with a suitable case of a motor-armature and a rotary drill-holder mounted coaxially therein, differential internal gears fixed one to the drill-holder and the other to the case or frame, said drill-holder being rotatable and the case stationary relatively to each other and the armature-shaft, and a crank fixed to the armature-shaft and provided on one side thereof with a pinion which meshes with both internal gears and on the other side with a counterweight, whereby motion is transmitted from the armature-shaft to the drill-holder through said pinion and differential gears, substantially as described.

3. In an electric drill the combination of a case or frame composed of coaxial sections comprising a motor field-piece, a fixed internal gear and end bearing-pieces, a drill-holder provided with an internal gear having a different number of teeth from the fixed gear, and a motor-armature provided with an eccentrically-mounted pinion meshing with both internal gears, said drill-holder being rotatable and the case stationary relatively to each other and the armature-shaft, whereby motion is transmitted to the drill-holder from the motor through said pinion and differential gears, substantially as described.



4. In an electric drill the combination with a case or frame provided with coaxial bearings, with a fixed internal gear and with a motor-field, of a motor-armature mounted in said bearings and provided with an eccentrically-mounted pinion meshing with said internal gear, and a rotary drill-holder having a central bearing on the armature-shaft, an end-thrust bearing on the case or frame and an internal gear meshing with said pinion, one of said gears having a different number of teeth from the other, and said drill-holder being rotatable and the case stationary relatively to each other and the armature-shaft, whereby motion is transmitted to the drill-holder from the motor-armature through said pinion and differential gears, substantially as described.

5. In an electric drill the combination of a case or frame composed of coaxial sections comprising a motor-field, a fixed internal gear and end pieces, of a motor-armature having bearings in said case or frame, and provided with an eccentrically-mounted pinion meshing with said gear, and a drill-holder having an end-thrust ball-bearing between it and said case or frame and an internal gear meshing with said pinion, one of said gears having a different number of teeth from the other, and said drill-holder being rotatable and the case stationary relatively to each other and the armature-shaft, whereby motion is transmitted to the drill-holder from the motor-armature through said pinion and differential gears, substantially as described.

810,445. HOISTING APPARATUS. CHARLES W. THIELEN, Brooklyn, N. Y., assignor to Edgewood Manufacturing Company, New York, N. Y. Filed Sept. 20, 1902. Serial No. 124,303.

Claim.—1. In combination, a hoisting or hauling rope containing two sections having different capacities for engagement, two members adapted for engagement with said hoisting or hauling rope parts, respectively, a slack-pulling rope and means whereby said slack-pulling rope is operatively connected with one of said members.

2. In combination, a hoisting or hauling rope containing two sections having different capacities for engagement, a slack-pulling rope and mechanism whereby said slack-pulling rope is operatively connected with one of said hoisting or hauling rope sections and disconnected from the other thereof.

3. In combination, a hoisting or hauling rope and a slack-pulling rope one of which contains two sections having different capacities for engagement and mechanism whereby said ropes are connected together during the passage of one of said sections and disconnected during the passage of the other thereof.

4. In a hoisting or conveying apparatus, a trackway, a load-carriage traveling thereon, two ropes, one of which is connected with said carriage and one of which contains two sections having different capacities for engagement, an actuating-drum for each rope, and mechanism whereby said ropes are operatively connected during the passage of one of said sections and disconnected during the passage of the other thereof.

5. In a hauling apparatus, in combination, a trackway, a carriage thereon, an outhaul-rope for said carriage, a hoisting or hauling rope composed of two sections having different capacities for engagement, a slack-pulling rope and mechanism supported by said carriage whereby said slack-pulling rope is operatively connected with said hoisting or hauling rope as one section thereof is passing and is operatively disconnected therefrom as the other section thereof is passing.

6. In a hauling apparatus, in combination, an elevated sheave-block, a hoisting or hauling rope mechanism on said block adapted to form a gripping engagement with one part of said hoisting or hauling rope and an ungripping engagement with another part thereof, an inhaul-drum connected with said rope and pay-out means acting upon said rope through said gripping connection.

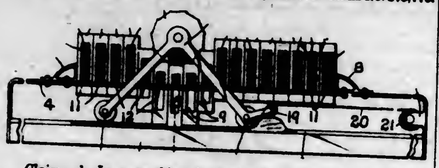
7. In combination, a rope 16, its drum 3, a sheave driven by said rope, a sheave movable independently thereof and a rope and means whereby it is transferred from one of said sheaves to the other in the course of its movement.

8. In combination, an elevated sheave-block, a rope-drum, a hoisting or hauling rope having a part of one capacity for engagement of sufficient length to extend from said block substantially to the ground and having another part of different capacity for engagement connecting said first part with said drum and pay-out mechanism operatively engaging said first part only.

9. In a hoisting apparatus, in combination, two ropes, an actuator for each rope, one of said ropes containing two sections having different capacities for engaging and mechanism whereby said ropes are operatively connected during the passage of one of said sections and disconnected during the passage of the other.

10. In a hoisting apparatus, in combination, two ropes extending to a distant point, one of which contains two sections having different capacities for engagement and mechanism located at said distant point whereby said ropes are operatively connected during the passage of one of said sections and disconnected during the passage of the other thereof.

810,446. WIRED-GLASS-MAKING MACHINE. ROBERT A. B. WALSH, St. Louis, Mo., assignor to Mississippi Glass Company, St. Louis, Mo., a Corporation of Missouri. Filed July 23, 1905. Serial No. 270,776.



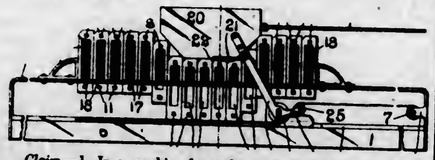
Claim.—1. In a machine for making wired glass, the combination with a base, of vertically-reciprocatory wire-positioning elements above the base, a roller movable over the wire-positioning elements and having offsetted portions for depressing them to position the wire; substantially as described.

2. In a machine for making wired glass, the combination with a base, of vertically-reciprocatory wire-positioning elements above the base, a roller movable over the wire-positioning elements and having offsetted portions for depressing them to position the wire, and means for rolling a sheet of glass; substantially as described.

3. In a machine for making wired glass, the combination with a base, of means for spreading the glass on the base, means for feeding wire on top of the glass, vertically-reciprocatory wire-impressing elements 6 above the base, and a roller movable over said wire-impressing elements for actuating them; substantially as described.

4. In a machine for making wired glass, the combination with a base, means for spreading the glass on the base, means for feeding wire on top of the glass, wire-impressing elements 6 resiliently supported above the base, and a roller 18 having projections for engaging the top edges of the elements 6 to actuate them; substantially as described.

810,447. MACHINE FOR MAKING WIRED PLATE-GLASS. ROBERT A. B. WALSH, St. Louis, Mo., assignor to Mississippi Glass Company, St. Louis, Mo., a Corporation of Missouri. Filed July 23, 1905. Serial No. 270,778.



Claim.—1. In a machine for making wired glass, the combination with a base, of reciprocatory wire-positioning elements carried by said base and arranged in transverse series above the same, of plate-forming elements reciprocatingly mounted between alternate wire-positioning elements, said plate-forming elements being capable of actuation only after the wire-positioning elements have been actuated, and means for actuating both sets of elements; substantially as described.

2. In a machine for making wired glass, the combination with a base, of reciprocatory wire-positioning elements above the base, a reciprocatory means for finishing the sheet of glass by pressing the upper surface thereof, and a weight movable over said wire-positioning elements and said finishing means to actuate first the wire-positioning elements and then the finishing means; substantially as described.

3. In a machine for making wired glass, the combination with a bed or base, of a roller for forming a sheet or plate on the base, vertically-reciprocatory wire-positioning elements for forcing the wire in position with respect to the glass, reciprocatory elements for engaging the glass to smooth out any inequalities formed by the wire-positioning elements, and a weight movable over the reciprocatory wire-positioning elements and the elements for engaging the glass to smooth out any inequalities, the last-named elements being actuated after the actuation of the reciprocatory wire-positioning elements; substantially as described.

4. In a machine for making wired glass, the combination with a base, of means for forming a sheet of glass on said base, means for feeding a wire mesh on the upper surface of the glass, punchers for embedding the wire mesh below the upper surface of the glass, reciprocatory smoothing elements between which said punchers are positioned, and means for actuating the punchers and the smoothing elements; substantially as described.

5. In a machine for forming wired plate-glass, the combination with a base, of means for spreading the glass upon the base, wire-impressing punchers above the base, vertically-movable smoothing elements between which said punchers are positioned, and a sliding element 20 for actuating the punchers and the smoothing elements; substantially as described.

810,448. ELEVATOR OR JACK. GUSTAVE WESSELMANN and EDWARD H. OVERHOLT, Streator, Ill., assignors to The Wesselmann Manufacturing Company, Streator, Ill., a Corporation of Illinois. Filed Sept. 23, 1903. Serial No. 174,269.

Claim.—1. A device of the class described comprising a deck, oppositely-disposed sills supporting the same, a carriage positioned on the deck and normally flush with the top thereof, upwardly-extending ways on said sills at each end of the carriage, sheaves thereon, guides on the carriage positively engaging the ways, a longitudinally-slidable winch-shaft journaled on the sills and extending parallel with the carriage, a drum at each end thereof, chains connecting the ends of the carriage and said drums and leading over said sheaves on the ways, power-operated means adapted to rotate the winch-shaft and means operated by longitudinal movement of said winch-shaft acting to permit said carriage to descend by gravity.

2. In a device of the class described a carriage, a longitudinally-slidable winch-shaft journaled parallel therewith, a rotative gear at one end thereof, a positively-driven snail-gear engaging the same, a drum on each end of said winch-shaft, a clutch adapted to engage said gear at one end of said shaft, a friction-brake on said shaft positioned to engage when said clutch is released and means for shifting said shaft longitudinally.

3. The combination with a deck or platform, of a longitudinally-slidable winch-shaft journaled thereon, a power-shaft at an angle with the winch-shaft, an intermeshing gear and snail-gear on said shafts respectively, a drum on said winch-shaft, a clutch affording connection between said drum and gear, a friction-brake on said winch-shaft positioned to engage when the clutch is released, and a lever engaged on the winch-shaft and acting to shift the shaft longitudinally.

4. A hoisting device comprising a supporting-frame, a longitudinally-slidable winch-shaft journaled thereon, a gear-wheel thereon, a driving-shaft at an angle with the winch-shaft, a snail-gear on the driving-shaft intermeshing with said gear and acting to elevate and support the load.

5. In a hoisting device a frame, a longitudinally-slidable winch-shaft journaled thereon, a gear revoluble on the winch-shaft, a clutch adapted to engage the gear and operated by longitudinal movement of the winch-shaft, a power-shaft arranged at an angle with the winch-shaft, a spiral or snail gear thereon in positive engagement with said gear on the winch-shaft, sheaves located above the winch-shaft, flexible connections extending from said winch-shaft over said sheaves, a friction-brake on the winch-shaft positioned to engage when the clutch is out of engagement whereby a weight suspended on said sheaves may be elevated and supported on said winch-shaft and gears and means acting to shift said shaft longitudinally disconnecting said clutch and supporting the weight on said friction-brakes.

6. A hoisting device embracing a driving-shaft, a snail-gear thereon, a rotatable and longitudinally-slidable winch-shaft, a revoluble gear thereon intermeshing with said snail-gear, a drum rigidly secured on said winch-shaft, a clutch comprising complemental ends on said drum and the gear-hub, a friction-brake positioned to be out of engagement when the clutch is connected and in engagement when the clutch is out of engagement, sheaves positioned above the winch-shaft, chains connected with the drum and extending over the sheaves, an upwardly and rearwardly movable carriage connected with said chains and adapted to be hoisted thereby, means acting to shift said winch-shaft longitudinally, a coupling on the main driving-shaft and automatically-operated means for disconnecting said coupling at a predetermined point in the elevation of the carriage.

7. In a device of the class described a rotative, longitudinally-slidable winch-shaft, a drum on each end thereof, bolts extending through said drums and into the shaft and nuts engaged on said bolts between said drum and the shaft, and a hoisting-chain engaged on one of said bolts on each drum, a clutch operated by longitudinal movement of the shaft and adapted to connect, and to disconnect the driving means therefrom and a friction-brake comprising interfitting parts adapted for engagement when the clutch is out of engagement.

8. In a machine of the class described, a frame, a longitudinally-slidable winch-shaft journaled thereon, a lever fulcrumed on the frame and positively engaging the winch-shaft, a drum on each end of the winch-shaft, bolts extending through said drums and into the shaft, a nut on each bolt between the drum and shaft, a hoisting-chain connected with each drum by means of one of said bolts, driving means for said shaft, a clutch formed by interfitting parts of the driving means and one of said drums, a friction-brake comprising a part carried on the other drum and a part rigid on said frame whereby shifting said shaft in one direction actuates the winch and in the other direction engages the friction-brake.

9. In a machine of the class described a winch-shaft, one or more drums thereon, a revoluble gear adjacent one of said drums, said drum and the gear-hub together affording a clutch, a driving-shaft, a snail-gear on said driving-shaft positioned to mesh with the gear on the winch-shaft and means affording longitudinal movement of the winch-shaft acting to disconnect said clutch.

10. In a machine of the class described a winch-shaft, one or more drums thereon, a revoluble gear adjacent one of said drums, said drum and the gear-hub together affording a clutch, a driving-shaft, a snail-gear on said driving-shaft positioned to mesh with the gear on the winch-shaft and means affording longitudinal movement of the winch-shaft acting to disconnect said clutch, and a friction-brake comprising a cup-shaped friction-disk adapted to receive a conical friction-disk, one of said disks being secured upon the frame and the other rigidly secured to said shaft and positioned to engage when the shaft is shifted to disconnect the clutch.

11. In a hoisting-machine the combination with a winch-shaft and a drum thereon, of a gear on said winch-shaft, a driving-shaft, a snail-gear on the driving-shaft acting to engage said gear and adapted to operate the winch, said snail-gear acting to support the load at any desired point during the hoisting operation.

12. In a hoisting device a revoluble longitudinally-slidable winch-shaft, driving means thereon, a clutch controlling said driving means, a friction-brake comprising male and female friction members one of which is rigidly secured on the frame and the other of which is secured on said shaft and a lever pivoted on the frame and positively engaging said shaft and acting to shift the same longitudinally.

13. In a device of the class described the combination with a platform, of an A-frame positioned at each end thereof, a carriage positioned between the A-frames the ends thereof engaging one leg of each A-frame, and acting to direct the carriage rearwardly and upwardly, a winch-shaft, a sheave at the top of each A-frame, a chain connecting said winch and carriage over said sheave, a main driving-shaft, a coupling in said main driving-shaft, a lever positioned adjacent one of the A-frames and acting to shift the coupling at a predetermined point in the movement of the carriage and coacting friction members on said winch-shaft and frame adapted to control the lowering of the carriage.

14. In a wagon-dump, the combination with standards and an elevating-frame located therebetween, means for raising and lowering the elevating-frame, connected mechanism acting automatically and independent of said elevating-frame for interrupting the upward movement of said elevating-frame.

15. In a hoisting device the combination with standards and an elevating-frame located therebetween, means for raising and lowering the elevating-frame, a trip mechanism and means acting independent of the elevating-frame to engage said trip mechanism and automatically interrupt the upward movement of said elevating-frame.

16. In a hoisting device the combination with standards, of an elevating-frame located therebetween, an adjustable trip mechanism carried on said standards, and means acting independently of said elevating-frame to engage said trip mechanism and automatically interrupt the upward movement of said frame.

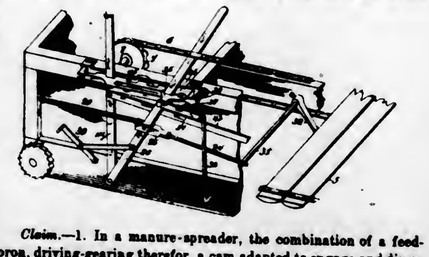
17. In a hoisting device the combination with standards provided with sheaves in the tops thereof, of a carriage thereon, a winch-shaft, a plurality of drums thereon, means for driving said winch-shaft, cables connected with said carriage and passing over said sheaves into engagement with said drums, an adjustable trip mechanism on said standards, connected with the driving means and means carried on one of said cables acting to automatically operate said trip-mechanism and interrupt the upward movement of the carriage.

18. In a hoisting device the combination with standards of a carriage adapted to travel thereon, means for operating said carriage, an adjustable trip mechanism carried on said standards and connected with the operating means, and adjustable means acting independently of the carriage to automatically interrupt the upward travel of said carriage.

19. In a hoisting device the combination with standards, of a carriage adapted to travel thereon, a hoisting-cable for said carriage, means for operating said cable, a trip mechanism on one of said standards comprising a sheave journaled on said standard, a chain trained over said sheave and connected at one end with the operating means, a plate engaged on the other end and pivoted on said standard and an adjustable bracket on said cable adapted to engage said plate and throw the operating means out of operative engagement.

20. In a hoisting device the combination with standards, of an elevating-platform, a winch-shaft, drums thereon, cables connecting said platform with said drums, driving means for said winch-shaft, a sheave journaled on said standards, a chain connected at one end with said driving means and trained over said sheave, an adjustable trigger-plate on the other end of said chain and a bracket adjustably engaged on one of said cables adapted to engage said trigger-plate and disconnect the driving means.

810,449. MANURE-SPREADER FEED MECHANISM. CHARLES W. WEST, Cedar Rapids, Iowa. Filed Jan. 3, 1905. Serial No. 239,315.



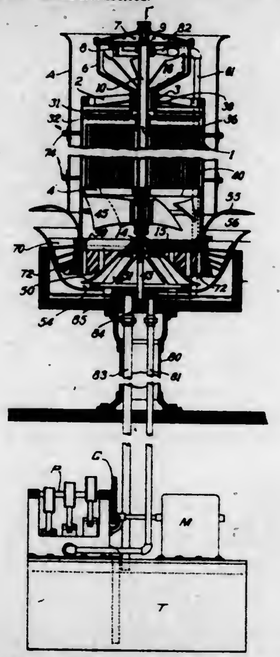
Claim.—1. In a manure-spreader, the combination of a feed-apron, driving-gearing therefor, a cam adapted to engage and disengage said gearing a shift-rod connecting with said cam, a lever connecting directly with said rod, a spring attached to the forward end of said rod and tending to pull it in a disengaging direction with respect to said gearing, a guide for the lever, a latch pivoted on said guide, and adapted to hold the lever in retracted position, a shaft with a crank linked to said latch and an arm depending in the path of the apron as it moves forwardly on the under side, whereby the feed-gearing is automatically disengaged as the apron reaches the extreme unloading position.

2. In a manure-spreader, the combination of a feed-apron, driving-gearing therefor, a hand-lever at one side of the machine a guide therefor, a latch mounted on the guide-casting to engage the lever when retracted mechanism for disengaging the feed-gearing, a rod connecting the same with the hand-lever, a tension-spring connecting with the front end of said rod, mechanism for disengaging the latch as the apron reaches the unloading limit of its movement, a shaft rotated by the movement of the apron through the medium of a sprocket-wheel, a ratchet on said shaft, a pawl to engage the same, and a link connecting said pawl with said hand-lever, substantially as and for the purpose set forth.

3. In a manure-spreader and combined with its feed-apron, a feed-drive therefor embracing a traction-wheel, a spur-gear connecting therewith, a spur and bevel gear engaging the same, a bevel-pinion engaging said bevel-gear, an inclined shaft for said pinion, a series of differential gears mounted on said shaft at right angles thereto, a shaft in line with the faces of said differential gears on one side, a pivoted bearing for one end thereof and a sliding bearing for the other end, a guide for said sliding bearing, a spur-pinion mounted to slide on the pivoted shaft, a lever and a connection for the same with said spur-pinion, a cam for raising and depressing the tilting shaft, a hand-lever connecting therewith, a worm at one end of said

shaft and a worm-gear engaging the same, an apron-driving sprocket and a shaft therefor taking said worm.

810,450. APPARATUS FOR TREATING AIR. FREDERICK WHITE, Boston, Mass., assignor to Regenerated Cold Air Company, Portland, Me., a Corporation of Maine. Filed Sept. 4, 1903. Renewed Nov. 11, 1905. Serial No. 268,708.



Claim.—1. The combination of a vented motor-wheel casing having interior antiswirling plates; a motor-wheel within said casing and fast on a shaft, the casing having a liquid-escape at its lowr end; means for directing a fluid-jet against said motor-wheel to rotate the same and said shaft; a liquid-distributer loose on said shaft but in frictional connection therewith, and thereby driven at a speed less than that of the motor-wheel, said distributer having a cup-like portion into which the liquid-discharge of the motor-casing discharges, and also having a plurality of radial, lengthwise-chambered distributing-arms provided with liquid-escapes on their under sides; a series of concentric cylinders mounted endwise at the liquid-escape side of said distributing-arms; means for keeping said cylinders in fixed position relatively to each other; an air-fan fixed on said shaft, the cylinders being between said distributing-arms and said fan; an open-ended main casing exterior to said cylinders; means for supporting said motor-casing in fixed relation to an end of said main casing; means for securing said cylinders in fixed relation to said main casing; the distributer, cylinders, and air-fan being within the main casing; an air-deflecting flange extending outwardly from the main casing; an air-deflector extending outwardly from the main casing and mounted at a distance from said flange, thereby forming a lateral air-escape from the main casing; a liquid-receiving pan below the main casing, said flange and deflector; a fluid-supply conduit to said jet; a fluid-escape conduit from said pan; a trap for said fluid-escape conduit; and a series of baffle-plates mounted in the air-escape and severally inclined crosswise to the blades of the air-fan.

2. The combination of a vented motor-wheel casing having interior antiswirling plates; a motor-wheel within said casing and fast on a shaft, the casing having a liquid-escape at its lower end; means for directing a fluid-jet against said motor-wheel to rotate the same and said shaft; a liquid-distributer loose on said shaft but in frictional connection therewith, and thereby driven at a speed less than that of the motor-wheel, said distributer having a cup-like portion into which the liquid-discharge of the motor-casing discharges, and also having a plurality of radial lengthwise-chambered distributing-arms provided with liquid-escapes on their under sides; a series of concentric cylinders mounted endwise at the liquid-escape side of said distributing-arms; means for keeping said cylinders in fixed position relatively to each other; an air-fan fixed on said shaft, the cylinders being between said distributing-arms and said fan; an open-ended main casing exterior to said cylinders; means for supporting said motor-casing in fixed relation to an end of said main casing; means for securing said cylinders in fixed relation to said main casing; the distributer, cylinders, and air-fan being within the main casing; an air-deflecting flange extending outwardly from the main casing; an air-deflector extending outwardly from the main casing and mounted a distance from said flange, thereby forming a lateral air-escape from the main casing; a liquid-receiving pan below the main casing, said flange and deflector; a fluid-supply conduit to said jet; a fluid-escape conduit from said pan; a trap for said fluid-escape conduit; and a series of baffle-plates mounted in the air-escape and severally inclined crosswise to the blades of the air-fan; and a tubular pedestal on which the pan is mounted and within which said two conduits are contained.

3. The combination of a vented motor-wheel casing having interior antiswirling plates; a motor-wheel within said casing and fast on a shaft, the casing having a liquid-escape at its lower end; means for directing a fluid-jet against said motor-wheel to rotate the same and said shaft; a liquid-distributer loose on said shaft but in frictional connection therewith, and thereby driven at a speed less than that of the motor-wheel, said distributer having a cup-like portion into which the liquid-discharge of the motor-casing discharges, and also having a plurality of radial, lengthwise-chambered distributing-arms provided with liquid-escapes on their under sides; a series of concentric cylinders mounted endwise at the liquid-escape side of said distributing-arms; means for keeping said cylinders in fixed position relatively to each other; an air-fan fixed on said shaft, the cylinders being between said distributing-arms and said fan; an open-ended main casing exterior to said cylinders; means for supporting said motor-casing in fixed relation to an end of said main casing; means for securing said cylinders in fixed relation to said main casing; the distributer, cylinders and air-fan being within the main casing; an air-deflecting flange extending outwardly from the main casing; an air-deflector extending outwardly from the main casing and mounted a distance from said flange, thereby forming a lateral air-escape from the main casing; a liquid-receiving pan below the main casing, said flange and deflector; a fluid-supply conduit to said jet; a fluid-escape conduit from said pan; a trap for said fluid-escape conduit; and a series of baffle-plates mounted in the air-escape and severally inclined crosswise to the blades of the air-fan; an open-ended, outer casing extending from said flange beyond the farther end of the main casing, and means for holding the outer casing in fixed relation to the main casing.

4. The combination of a vented motor-wheel casing having interior antiswirling plates; a motor-wheel within said casing and fast on a shaft, the casing having a liquid-escape at its lower end; means for directing a fluid-jet against said motor-wheel to rotate the same and said shaft; a liquid-distributer loose on said shaft but in frictional connection therewith, and thereby driven at a speed less than that of the motor-wheel, said distributer having a cup-like portion into which the liquid-discharge of the motor-casing discharges, and also having a plurality of radial, lengthwise-chambered distributing-arms provided with liquid-escapes on their under sides; a series of concentric cylinders mounted endwise at the liquid-escape side of said distributing-arms; means for keeping said cylinders in fixed position relatively to each other; an air-fan fixed on said shaft, the cylinders being between said distributing-arms and said fan; an open-ended main casing exterior to said cylinders; means for supporting said motor-casing in fixed relation to an end of said main casing; means for securing said cylinders in fixed relation to said main casing; the distributer, cylinders, and air-fan being within the main casing; an air-deflecting flange extending outwardly from the main casing; an air-deflector extending outwardly from the main casing and mounted a distance from said flange, thereby forming a lateral air-escape from the main casing; a liquid-receiving pan below the main casing, said flange and deflector; a fluid-supply conduit to said jet; a fluid-escape conduit from said pan; a trap for said fluid-escape conduit; and a series of baffle-plates mounted in the air-escape and severally inclined crosswise to the blades of the air-fan; a sound-deadener on that portion of the main casing which is opposed to the outer ends of the air-fan.

5. The combination of a vented motor-wheel casing having interior antiswirling plates; a motor-wheel within said casing and fast on a shaft, the casing having a liquid-escape at its lower end; means for directing a fluid-jet against said motor-wheel to rotate the same and said shaft; a fluid-distributer loose on said shaft but in frictional connection therewith, and thereby driven at a speed less than that of the motor-wheel, said distributer having a cup-like portion into which the liquid-discharge of the motor-casing discharges, and also having a plurality of radial, lengthwise-chambered distributing-arms provided with liquid-escapes on their under sides; a series of concentric cylinders mounted endwise at the liquid-escape side of said distributing-arms; means for keeping said cylinders in fixed position relatively to each other; an air-fan fixed on said shaft, the cylinders being between said distributing-arms and said fan; an open-ended main casing exterior to said cylinders; means for supporting said motor-casing in fixed relation to an end of said main casing; means for securing said cylinders in fixed relation to said main casing; the distributer, cylinders, and air-fan being within the main casing; an air-deflecting flange extending outwardly from the main casing; an air-deflector extending outwardly from the main casing and mounted a distance from said flange, thereby forming a lateral air-escape from the main casing; a liquid-receiving pan below the main casing, said flange and deflector; a fluid-supply conduit to said jet; a fluid-escape conduit from said pan; a trap for said fluid-escape conduit; and a series of baffle-plates mounted in the air-escape and severally inclined crosswise to the blades of the air-fan, the fluid-escape of the motor-casing extending into the cup-like portion of the distributer but out of contact therewith.

6. The combination of a vented motor-wheel, casing having interior antiswirling plates; a motor-wheel within said casing and fast on a shaft, the casing having a liquid-escape at its lower end; means for directing a fluid-jet against said motor-wheel to rotate the same and said shaft; a liquid-distributer loose on said shaft but in frictional connection therewith, and thereby driven at a speed less than that of the motor-wheel, said distributer having a cup-like portion into which the liquid-discharge of the motor-casing discharges, and also having a plurality of radial, lengthwise-chambered distributing-arms provided with liquid-escapes on their under sides; a series of concentric cylinders mounted endwise at the liquid-escape side of said distributing-arms; means for keeping said cylinders in fixed position relatively to each other; an air-fan fixed on said shaft, the cylinders being between said distributing-arms and said fan; an open-ended main casing exterior to said cylinders; means for supporting said motor-casing in fixed relation to an end of said main casing; means for securing said cylinders in fixed relation to said main casing; the distributer, cylinders, and air-fan being within the main casing; an air-deflecting flange extending outwardly from the main casing; an air-deflector extending outwardly from the main casing and mounted a distance from said flange, thereby forming a lateral air-escape from the main casing; a liquid-receiving pan below the main casing, said flange and deflector; a fluid-supply conduit to said jet; a fluid-escape conduit from said pan; a trap for said fluid-escape conduit; and a series of baffle-plates mounted in the air-escape and severally inclined crosswise to the blades of the air-fan; the main casing having a fluid-escape hole through its wall into the space between the opposed walls of the main casing and flange.

7. The combination of a vented motor-wheel casing having interior antiswirling plates; a motor-wheel within said casing and fast on a shaft, the casing having a liquid-escape at its lower end; means for directing a fluid-jet against said motor-wheel to rotate the same and said shaft; a liquid-distributer loose on said shaft but in frictional connection therewith, and thereby driven at a speed less than that of the motor-wheel, said distributer having a cup-like portion into which the liquid-discharge of the motor-casing discharges, and also having a plurality of radial, lengthwise-chambered distributing-arms provided with liquid-escapes on their under sides; a series of concentric cylinders mounted endwise on the liquid-escape side of said distributing-arms; means for keeping said cylinders in fixed position relatively to each other; an air-fan fixed on said shaft, the cylinders being between said distributing-arms and said fan; an open-ended main casing exterior to said cylinders; means for supporting said motor-casing in fixed relation to an end of said main casing; means for securing said cylinders in fixed relation to said main casing; the distributer, cylinders, and air-fan being within the main casing; an air-deflecting flange extending outwardly from the main casing; an air-deflector extending outwardly from the main casing and mounted a distance from said flange, thereby forming a lateral air-escape from the main casing; a liquid-receiving pan below the main casing, said flange and deflector; a fluid-supply conduit to said jet; a fluid-escape conduit from said pan; a trap for said fluid-escape conduit; and a series of baffle-plates mounted in the air-escape and severally inclined crosswise to the blades of the air-fan, the motor-wheel being near the upper end of the main casing; and the fan being a suction-fan whereby air is drawn into the upper end of the main casing and sucked downwardly over the films of fluid gravitating down the walls of the upright cylinders.

8. The combination of a fluid-supply tank; a motor; a pump driven thereby; a pan; a fluid-escape conduit from the pan into the tank; an air-treating apparatus mounted above said pan, and comprising a vented motor-wheel casing; a motor-wheel within said casing; a shaft on which the motor-wheel is fast; a fluid-distributer loose on said shaft but driven by frictional connection therewith and below the motor-wheel casing, the latter discharging into the distributer and the motor-wheel casing being provided with interior antiswirling plates; a series of open-ended, vertical sheet-metal cylinders fixed at distances apart; a main casing; an air-suction fan fast on said shaft and below the lower ends of said cylinders; a tubular standard on the upper end of which said pan is mounted; and a conduit from said pump to the motor-wheel casing and discharging pumped fluid against the wheel to rotate it, both conduits being within the tubular standard.

9. In air-cooling apparatus, a main casing; an open motor-wheel-casing-supporting frame on its upper end; a motor-casing on said frame; a motor-wheel within said casing; a shaft on which the motor-wheel is fixed; a fluid-distributer loose on said shaft but in frictional connection therewith; a collar fixed on said shaft, the distributer resting on said collar; an air-fan fast on said shaft; a series of vertically-mounted concentric cylinders of varying diameters between the fan and distributer; the motor-casing discharging into the distributer and the distributer having a plurality of radial, lengthwise-chambered arms closed at their outer ends, and formed with liquid-escapes on their under sides; the main casing extending below the fan and above the distributer; a pan below the main casing; a fluid-escape conduit from the pan; and a conduit entering the motor-casing and discharging against the motor-wheel therein.

10. In air-treating apparatus, the combination of a motor-wheel casing having an interior antiswirling plate and a fluid-discharge on its under side; a motor-wheel within said casing; a shaft on which the motor-wheel is fast; a fluid-distributer on said shaft, the motor-wheel casing discharging into the distributer; means for supporting the distributer on said shaft, the distributer being driven by frictional connection with the shaft and having a radial, lengthwise-chambered distributing-arm formed with a fluid-escape; a series of plates separated one from the other, and over and between which the fluid from the distributer flows; an air-fan fast on said shaft; the plates being between the distributer and the fan; a pan below the fan; an air-escape passage above the pan; and means in the air-escape passage to prevent outward spattering of fluid while permitting the escape of air through said passage.

11. In air-treating apparatus, the combination of a shaft; a motor-wheel fixed thereon; an air-fan fixed thereon; a fluid-receiving distributer loose thereon but in frictional connection therewith and thereby rotatable at a speed less than that of the motor and fan; a series of separated non-absorbent plates between the distributer and fan, and over and between which the distributer distributes; an open-ended main casing exterior to the distributer, the plates and the fan; means for rotating the motor; and means of supplying fluid to the distributer.

12. In air-treating apparatus, the combination of a shaft; a motor-wheel fast on it; an air-fan fast on it; a fluid-distributer mounted on it in frictional connection therewith and having lengthwise-chambered, radial arms, closed at their outer ends, and the arms each having a plurality of fluid-escapes between their outer and inner ends; and a series of plates spaced apart and mounted between the radial arms and air-fan; means for rotating the motor-wheel; and means for supplying the distributer with fluid.

13. The combination of a rotatable shaft; an air-fan fast thereon, and driven thereby; a liquid-distributer loose on the shaft, and means for supplying liquid to said distributer.

14. The combination of a rotatable shaft; an air-fan fast on the shaft, and thereby driven; a fluid-distributer loose on the shaft and comprising a central liquid-receiving cap and a plurality of lengthwise-chambered radial distributing-tubes; means for supplying fluid to the distributer; and a series of concentric cylinders mounted endwise below the distributer and receiving on their surfaces the fluid from the distributer.

15. The combination of a vented water-wheel casing having an outlet; a water-wheel shaft; a water-wheel fast on the shaft; a conduit for the wheel-driving current and entering the casing in operative proximity to the water-wheel; a liquid-distributer loose on said shaft, the water-wheel casing discharging into said distributer; and a series of concentric, endwise-mounted cylinders below said dis-

tributer, the distributer discharging thereon; and an air-fan fast on the shaft.

16. The combination of the motor-wheel casing having interior, antiswirling plates; a motor-wheel within said casing; an air-fan; means for exposing fluid from said casing to a current of air; a frictionally-driven fluid-distributer for distributing fluid from said casing on said exposing means; a shaft on which the motor-wheel and fan are fixed; the casing discharging the motor-driving fluid to the distributing means which distribute it over the exposing means; and the fan causing air to travel over the fluid on the exposing means.

17. The combination of a vented water-wheel casing having an outlet; a water-wheel shaft; a water-wheel fast on the shaft; a conduit for the wheel-driving current and entering the casing in operative proximity to the water-wheel; a liquid-distributer loose on said shaft, the water-wheel casing discharging into said distributer; and a series of concentric, endwise-mounted cylinders below said distributer, the distributer discharging thereon; and an air-fan fast on the shaft, the fan expelling air from the apparatus and having laterally-inclined vanes; a series of baffle-plates opposite the outer ends of the vanes and set crosswise to the vanes.

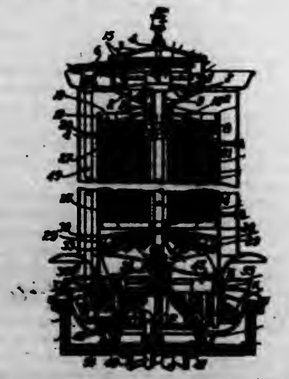
18. The combination of a motor-wheel and its casing with a rotatable shaft and a water-distributer on the shaft, the distributer traveling at a speed less than that of the shaft.

19. The combination of the outer casing with a troughed support therefor having fluid-discharge outlets; a shaft; an air-fan fast on the shaft; plates within the casing on which fluid is exposed; means for supplying fluid to the plates; and means for rotating the shaft.

20. The combination of a shaft; means for rotating it; an air-fan fast on the shaft; a casing within which the shaft and fan are contained; means within the casing for exposing fluid to air caused by the fan to travel downwardly through the casing; a fluid-distributer frictionally driven from said shaft; a pan below the casing, leaving an air-escape space between the lower end of the casing and the upper edge of the pan for the outward escape of air from the casing; a cone-like support within the pan and above the upper portion of which the casing is supported, the walls of the support inclining downwardly and outwardly; an air-deflector extending upwardly from within and outwardly of the pan; an upwardly and outwardly extending flange at the lower end of the casing, the air-escape passage being between said deflector and flange; and means in said passage to permit the exit of air through and to prevent fluid from spattering outwardly therethrough.

21. The combination of the outer casing; the troughed support therefor; an air-suction fan within the casing and near the troughed support; the air-deflecting flanges one above the other at a distance apart; a series of baffle-plates arranged edgewise in said space between said flanges; and a series of downwardly-extending fluid-escape tubes opening out of said trough.

810,451. APPARATUS FOR TREATING AIR. FREDERICK WHITE, South Boston, Mass., assignor to Regenerated Cold Air Company, Kittery, Me., a Corporation of Maine. Filed Aug. 8, 1904. Renewed Nov. 11, 1905. Serial No. 286,791.



Claim.—1. The combination of a motor-wheel casing; a motor-wheel fast on its shaft; an air-fan fast on said shaft; between said wheel and fan, a series of concentric, open-ended cylinders spaced apart; a rotatable liquid-distributer which rotates slower than the fan, is opposed to the cylinder ends, and supported by a stationary part of the machine, the casing being vented.

2. The combination of a motor-wheel casing; a motor-wheel fast on its shaft; an air-fan fast on said shaft; between said wheel and fan, a series of concentric, open-ended cylinders spaced apart; a rotatable liquid-distributer which rotates slower than the fan, is opposed to the cylinder ends, and supported by a stationary part of the machine; a pair of annular air-deflectors spaced apart; and an annulus of separated baffle-plates in said space.

3. The combination of a motor-wheel casing; a motor-wheel fast on its shaft; an air-fan fast on said shaft; between said wheel and fan, a series of concentric, open-ended cylinders spaced apart; a rotatable liquid-distributer which rotates slower than the fan, is opposed to the cylinder ends and supported by a stationary part of the machine; a pair of annular air-deflectors spaced apart; an annulus of separated baffle-plates in said space; and an annulus of separated baffle-plates between the cylinders and air-fan.

4. The combination of a motor-wheel casing; a motor-wheel fast on its shaft; an air-fan fast on said shaft; between said wheel and fan, a series of concentric, open-ended cylinders spaced apart; a rotatable liquid-distributer which rotates slower than the fan, is opposed to the cylinder ends and supported by a stationary part of the machine; a pair of annular air-deflectors spaced apart; an annulus of separated baffle-plates in said space; a shell inclosing said cylinders; a troughed annular frame into which the shell discharges; and a series of discharge-tubes depending from the trough and extending below the baffle-plates which are inclined crosswise to the inclination of the vanes of the air-fan.

5. The combination with a motor-wheel casing; a motor-wheel; its shaft; an air-fan fast on the shaft; a series of concentric open-ended cylinders; annular air-deflectors spaced apart; a supply-pipe and an escape-pipe, all substantially such as described, of means for preventing the escape of water through the space between the air-deflectors; and means for distributing water over said cylinders in a series of separated streams.

6. In apparatus substantially such as described, the combination of a motor-wheel casing; a regulable liquid-jet nozzle therefor; an air-fan fast on a shaft on which the motor-wheel is fast; and a liquid-distributer which has arms provided with regulable vanes against which liquid from said wheel strikes, and also has troughed arms with liquid-escape ports.

7. In apparatus substantially such as described, the combination of a pan; an upwardly and outwardly extending air-deflector therein having such shape as to form a dead-air space at the lower corner of the pan.

810,452. NON-REFILLABLE BOTTLE. CHARLES L. B. WOLF, New York, N. Y. Filed Feb. 1, 1905. Serial No. 243,686.

Claim.—1. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages, and a valve comprising a circular disk adapted to rest on said seat and having legs engaging and slidable against said annulus, substantially as described.

2. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages, a valve comprising a circular disk adapted to rest on said seat and having legs engaging and slidable against said annulus and provided with laterally-projecting feet engaging and slidable against the interior surface of the plug, substantially as described.

3. The combination with the neck of a receptacle having a ver-

tical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages, a valve comprising a circular disk adapted to rest on said seat and having laterally-extending projections and downwardly-extending legs engaging and slidable against said annulus and provided with laterally-extending feet, said feet and projections engaging and slidable against the interior surface of the plug, substantially as described.

4. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages, a valve comprising a circular disk adapted to rest on said seat and having legs engaging and slidable against said annulus and a gravity-sphere above said valve, substantially as described.

5. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages, a valve comprising a circular disk adapted to rest on said seat and having legs engaging and slidable against said annulus, and provided with laterally-projecting feet engaging and slidable against the interior surface of the plug, and a gravity-sphere above said valve, substantially as described.

6. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages, a valve comprising a circular disk adapted to rest on said seat and having laterally-extending projections and downwardly-extending legs engaging and slidable against said annulus and provided with laterally-extending feet, said feet and projections engaging and slidable against the interior surface of the plug, and a gravity-sphere above said valve, substantially as described.

7. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages and a circular series of converging lugs, and a valve comprising a circular disk adapted to rest on said seat and having legs engaging and slidable against said annulus, substantially as described.

8. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages and a circular series of converging lugs, a valve comprising a circular disk adapted to rest on said seat and having legs engaging and slidable against said annulus, and provided with laterally-projecting feet engaging and slidable against the interior surface of the plug, substantially as described.

9. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages and a circular series of converging lugs, a valve comprising a circular disk adapted to rest on said seat and having laterally-extending projections and downwardly-extending legs engaging and slidable against said annulus and provided with laterally-extending feet, said feet and projections engaging and slidable against the interior surface of the plug, substantially as described.

10. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages and a circular series of converging lugs, a valve comprising a circular disk adapted to rest on said seat and having legs engaging and slidable against said annulus, and a gravity-sphere above said valve, substantially as described.

11. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages and a circular series of converging lugs, a valve comprising a circular disk adapted to rest on said seat and having legs engaging and slidable against said annulus, and provided with laterally-projecting feet engaging and slidable against the interior surface of the plug and a gravity-sphere above said valve, substantially as described.

12. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages and a circular series of converging lugs, a valve comprising a circular disk adapted to rest on said seat and having laterally-extending projections and downwardly-extending legs engaging and slidable against said annulus and provided with laterally-extending feet, said feet and projections engaging and slidable against the interior surface of the plug, and a gravity-sphere above said valve, substantially as described.

13. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages and a circular series of converging lugs, a valve comprising a circular disk adapted to rest on said seat and having an upwardly-projecting rounded protuberance and downwardly-extending legs engaging and slidable against said annulus, and a gravity-sphere above said valve, substantially as described.

14. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages and a circular series of converging lugs, a valve comprising a circular disk adapted to rest on said seat and having an upwardly-projecting rounded protuberance and downwardly-extending legs engaging and slidable against said annulus and provided with laterally-projecting feet engaging and slidable against the interior surface of the plug and a gravity-sphere above said valve, substantially as described.

15. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages and a circular series of converging lugs, a valve comprising a circular disk adapted to rest on said seat and having an upwardly-projecting rounded protuberance, laterally-extending projections and downwardly-extending legs engaging and slidable against said annulus and provided with laterally-extending feet, said feet and projections slidable against the interior surface of the plug and a gravity-sphere above said valve, substantially as described.

16. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages, means for locking the plug within the neck and a valve comprising a circular disk adapted to rest on said seat and having legs engaging and slidable against said annulus, substantially as described.

17. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages, means for locking the plug within the neck, a valve comprising a circular disk adapted to rest on said seat and having legs engaging and slidable against said annulus and provided with laterally-projecting feet engaging and slidable against the interior surface of the plug, substantially as described.

18. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages, means for locking the plug within the neck, a valve comprising a circular disk adapted to rest on said seat and having laterally-extending projections and downwardly-extending legs engaging and slidable against said annulus and provided with laterally-extending feet, said feet and projections engaging and slidable against the interior surface of the plug, substantially as described.

19. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages and a circular series of converging lugs, means for locking the plug within the neck, a valve comprising a circular disk adapted to rest on said seat and having legs engaging and slidable against said annulus, and a gravity-sphere above said valve, substantially as described.

20. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages and a circular series of converging lugs, means for locking the plug within the neck, a valve comprising a circular disk adapted to rest on said seat and having legs engaging and slidable against said annulus and provided with laterally-projecting feet engaging and slidable against the interior surface of the plug and a gravity-sphere above said valve, substantially as described.

21. The combination with the neck of a receptacle having a vertical annulus forming a valve-seat, of a cylindrical plug located in said neck and provided with baffle-passages and a circular series of converging lugs, means for locking the plug within the neck, a valve comprising a circular disk adapted to rest on said seat and having laterally-extending projections and downwardly-extending legs engaging and slidable against said annulus and provided with laterally-extending feet, said feet and projections engaging and slidable against the interior surface of the plug, and a gravity-sphere above said valve, substantially as described.

22. The combination with a receptacle-neck containing a seating, of a valve movably guided relative to said seating, a plug within the neck and embodying a circular series of converging lugs, and a partition contributing to form a baffling-passage and having a stop located centrally with regard to the inner ends of the lugs, a gravity-

sphere between said lugs and valve, whereby when the neck is in a vertical position, the sphere will coact with the lugs at one side and with the valve, to lock the latter in a closed position upon the seating, and upon the tilting of the neck, the sphere will assume a clearance position at the inner ends of the lugs and limited by the stop to permit the uncoating of the valve and discharge of the liquid.

23. The combination with a receptacle-neck containing a seating and having an inner guiding-surface contiguous to said seating, of a valve having vertical means guided on the seating, said valve also having upper and lower lateral projections coacting with said inner surface to guide the valve, and an upper portion within the neck and containing baffling-passages.

810,453. LAND-ROLLER. JOHN H. WOLF, Cottagegrove, Wis. Filed Mar. 28, 1905. Serial No. 252,555.

Claim.—1. In an implement of the class described, the combination of a frame, supporting members pivoted at the front ends thereof to the frame, rollers carried by the rear ends of the supporting-bars aforesaid, bars arranged across the frame, springs between said bars and the supporting members of the rollers, and levers pivoted at their front ends to the frame and having adjustable connection with the bars aforesaid.

2. In an implement of the class described, the combination of a frame, supporting members pivoted at the front ends thereof to the frame, rollers carried by the rear ends of the supporting-bars aforesaid, bars arranged across the frame, springs between said bars and the supporting members of the rollers, levers pivoted at their front ends to the frame and having adjustable connection at their rear ends with the frame, and connecting means between the levers and the bars aforesaid.

3. In a implement of the class described, the combination of a frame, a pintle-bar mounted in the frame, supporting members pivoted at their front ends to the pintle-bar, rollers at the rear ends of the supporting members, adjusting-levers pivoted to the pintle-bars and arranged at opposite sides of the frame, connecting means between said adjusting-levers and the supporting members of the rollers, and means for adjusting the adjusting-levers.

4. In an implement of the class described, the combination of a frame, a pintle-bar mounted in the front portion of the frame, supporting members pivoted at their front ends to the pintle-bar and comprising spaced bars, blocks connecting the bars of each supporting member at a point between the ends thereof, rollers journaled between the spaced bars of each supporting member at the rear portions of the latter, adjusting-levers pivoted at their front ends to the pintle-bars and having adjustable connection at their rear ends with the frame, transverse bars extended across the frame and adjustably connected at the ends of the adjusting-levers aforesaid, and springs interposed between the transverse bars and the blocks of the supporting members of the rollers.

810,454. PROCESS OF MAKING STANNIC CHLORID. CHARLES B. ACKER, Niagara Falls, N. Y., assignor to Acker Process Company, a Corporation of New Jersey. Filed June 8, 1903. Renewed June 14, 1905. Serial No. 265,527.

Claim.—1. The method of making stannic chlorid, which consists in bringing metallic tin into contact with a solvent containing chlorin, thereby producing a solution containing stannous chlorid, and subjecting said solution to the action of a gaseous mixture containing free chlorin and a diluent, the diluent being in sufficient proportion to prevent undue rise of temperature, substantially as described.

2. The method of making stannic chlorid which consists in bringing metallic tin into contact with a solvent containing chlorin, thereby producing a solution containing stannous chlorid, and subjecting said solution to the action of a gaseous mixture containing free chlorin, hydrochloric acid and a diluent, the diluent being in sufficient proportion to prevent undue rise of temperature, substantially as described.

3. The method of making stannic chlorid which consists in bringing metallic tin into contact with a solvent containing chlorin, thereby producing a solution containing stannous chlorid, and subjecting said solution to the action of a gaseous mixture containing free chlorin, hydrochloric acid, and atmospheric air, the air being in sufficient proportion to prevent undue rise of temperature, substantially as described.

4. The method of making solutions containing stannic chlorid which consists in bringing metallic tin into contact with a solvent containing chlorin, thereby producing a solution of stannous chlorid, subjecting said solution to the action of free chlorin to convert it into stannic chlorid, bringing said stannic chlorid into contact with further quantities of tin, and again converting it into stannic chlorid, and repeating the operation until the desired concentration is reached, substantially as described.

5. The method of making highly-concentrated solutions containing stannic chlorid which consists in bringing metallic tin into contact with a solvent containing chlorin, thereby producing a solution of stannous chlorid, subjecting said solution to the action of free chlorin to convert it into stannic chlorid, bringing said stannic chlorid into contact with further quantities of tin, and again converting it into stannic chlorid, and repeating the operation until the concentration exceeds 1.800 specific gravity, substantially as described.

6. The method of making solutions containing stannic chlorid which consists in bringing metallic tin into contact with a solvent containing chlorin, thereby producing a solution of stannous chlorid, subjecting said solution to the action of a gaseous mixture containing free chlorin and hydrochloric acid to convert it into stannic chlorid, bringing said stannic chlorid into contact with further quantities of tin, and again converting it into stannic chlorid, and repeating the operation until the desired concentration is reached, substantially as described.

7. The method of making solutions containing stannic chlorid which consists in bringing metallic tin into contact with a solvent containing chlorin, thereby producing a solution of stannous chlorid, subjecting said solution to the action of a gaseous mixture containing free chlorin hydrochloric acid and oxygen to convert it into stannic chlorid, bringing said stannic chlorid into contact with further quantities of tin, and again converting it into stannic chlorid, and repeating the operation until the desired concentration is reached, substantially as described.

8. The method of making solutions containing stannic chlorid which consists in bringing metallic tin into contact with a solvent containing chlorin, thereby producing a solution of stannous chlorid, subjecting said solution to the action of a gaseous mixture containing free chlorin, hydrochloric acid and atmospheric air to convert it into stannic chlorid, bringing said stannic chlorid into contact with further quantities of tin, and again converting it into stannic chlorid, and repeating the operation until the desired concentration is reached, substantially as described.

9. The herein-described method of making stannic chlorid, which consists in subjecting a solution containing stannous chlorid to the action of a gaseous mixture containing free chlorin and a diluent, the diluent being in sufficient proportion to prevent undue rise of temperature, substantially as described.

10. The herein-described method of making stannic chlorid, which consists in subjecting a solution containing stannous chlorid to the action of a gaseous mixture containing free chlorin, hydrochloric acid and a diluent, the diluent being in sufficient proportion to prevent undue rise of temperature, substantially as described.

11. The herein-described method of making stannic chlorid, which consists in subjecting a solution containing stannous chlorid to the action of a gaseous mixture containing free chlorin, hydrochloric acid and atmospheric air, substantially as described.

12. The method of making stannic chlorid, which consists in subjecting a solution containing stannous chlorid to the action of a fluid containing free chlorin, thereby producing a solution containing stannic chlorid, bringing said stannic-chlorid solution into contact with metallic tin to form stannous chlorid, and subjecting said stannous-chlorid solution to the action of a fluid containing free chlorin, substantially as described.

13. The method of making stannic chlorid, which consists in subjecting a solution containing stannous chlorid to the action of a fluid containing free chlorin, thereby producing a solution containing stannic chlorid, bringing said stannic-chlorid solution into contact with metallic tin to form stannous chlorid, subjecting said stannous-chlorid solution to the action of a fluid containing free chlorin, and repeating the operation until the desired concentration is reached, substantially as described.

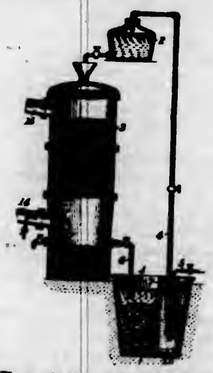
14. The method of making stannic chlorid, which consists in subjecting a solution containing stannous chlorid to the action of a fluid containing free chlorin, thereby producing a solution containing stannic chlorid, bringing said stannic-chlorid solution into contact with metallic tin to form stannous chlorid, subjecting said stannous-chlorid solution to the action of a fluid containing free chlorin, and repeating the operation until the concentration exceeds 1.8 specific gravity, substantially as described.

15. The method of making stannic chlorid, which consists in subjecting a solution containing stannic chlorid to the action of metallic tin, thereby forming stannous chlorid, and subjecting said stannous-chlorid solution to the action of a fluid containing free chlorin to produce a solution containing an increased amount of stannic chlorid, substantially as described.

16. The herein-described method of producing solutions containing stannic chlorid, which consists in subjecting a solution capable of dissolving tin as chlorid to the successive action of metallic tin and a fluid containing free chlorin, substantially as described.

17. The herein-described method of producing solutions containing chlorid of tin, which consists in subjecting a solution containing a compound of chlorin to the alternate action of metallic tin and a fluid containing free chlorin, substantially as described.

810,455. PROCESS OF MAKING STANNOUS CHLORID. CHARLES B. ACKER, Niagara Falls, N. Y., assignor to Acker Process Company, a Corporation of New Jersey. Filed June 8, 1903. Renewed June 14, 1905. Serial No. 265,526.



Claim.—1. The method of making stannous chlorid which consists in bringing metallic tin into contact with a solvent containing chlorin, thereby producing a solution containing stannous chlorid, subjecting said solution to the action of a gaseous mixture containing free chlorin, hydrochloric acid, and atmospheric air, substantially as described.

2. The method of making stannous chlorid which consists in bringing metallic tin into contact with a solvent containing chlorin, thereby producing a solution containing stannous chlorid, subjecting said solution to the action of free chlorin to form stannic chlorid, bringing said solution of stannic chlorid into contact with metallic tin to again form stannous chlorid, repeating the operation until the concentration of the stannic-chlorid solution exceeds 1.800, reducing said solution to stannous chlorid by contact with tin, and permitting said stannous-chlorid solution to crystallize, substantially as described.

4. The method of making stannous chlorid which consists in bringing metallic tin into contact with a solvent containing chlorin at a temperature above normal, thereby producing a solution containing stannous chlorid, subjecting said solution to the action of a fluid containing free chlorin to form stannic chlorid, bringing said solution of stannic chlorid into contact with metallic tin to again form stannous chlorid, repeating the operation until the concentration of the stannic-chlorid solution exceeds 1.800, reducing said solution to stannous chlorid by contact with tin, and permitting said stannous-chlorid solution to cool, whereby crystals of stannous chlorid are obtained, substantially as described.

5. The method of making stannous chlorid which consists in bringing metallic tin into contact with a solvent containing chlorin, thereby producing a solution containing stannous chlorid, subjecting said solution to the action of a gaseous mixture containing free chlorin and hydrochloric acid to form stannic chlorid, and bringing said solution of stannic chlorid into contact with metallic tin to again form stannous chlorid, substantially as described.

6. The method of making stannous chlorid which consists in bringing metallic tin into contact with a solvent containing chlorin, thereby producing a solution containing stannous chlorid, subjecting said solution to the action of a gaseous mixture containing free chlorin, hydrochloric acid, and atmospheric air to form stannic chlorid, and bringing said solution of stannic chlorid into contact with metallic tin to again form stannous chlorid, substantially as described.

7. The herein-described method of producing solutions containing stannous chlorid, which consists in subjecting solutions containing tin to the successive action of a fluid containing free chlorin and metallic tin, substantially as described.

8. The method of making stannous chlorid, which consists in subjecting solutions containing stannous chlorid to the action of a fluid containing free chlorin to form stannic chlorid, and bringing said stannic chlorid into contact with metallic tin, thereby producing a solution containing an increased amount of stannous chlorid, substantially as described.

810,456. PROCESS OF MAKING CHLORIN COMPOUNDS OF TIN. CHARLES B. ACKER, Niagara Falls, N. Y., assignor to Acker Process Company, a Corporation of New Jersey. Filed Dec. 30, 1903. Renewed June 14, 1905. Serial No. 265,529.

Claim.—1. The herein-described method of making chlorin compounds of tin, which consists in subjecting a solvent for tin to the alternate action of metallic tin and chlorin, and cooling the solution, whereby the tendency to produce metastannic compounds is avoided, substantially as described.

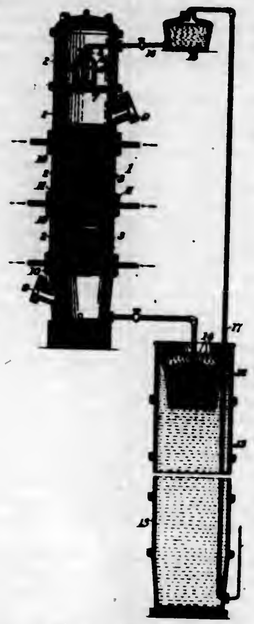
2. The herein-described method of making chlorin compounds of tin, which consists in subjecting a solvent for tin to the alternate and repeated action of metallic tin and chlorin, and cooling the solution, whereby the tendency to produce metastannic compounds is avoided, substantially as described.

3. The herein-described method of making chlorin compounds of tin, which consists in subjecting a solvent for tin to the alternate action of metallic tin and a gaseous mixture containing chlorin, and cooling the solution, whereby the tendency to produce metastannic compounds is avoided, substantially as described.

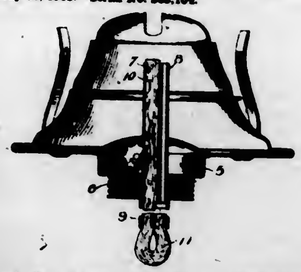
4. The herein-described method of making chlorin compounds of tin, which consists in subjecting a solvent for tin to the alternate and repeated action of metallic tin and a gaseous mixture containing chlorin, and cooling the solution, whereby the tendency to produce metastannic compounds is avoided, substantially as described.

5. The herein-described method of making chlorin compounds of tin, which consists in subjecting a solvent for tin to the alternate action of metallic tin and a gaseous body containing chlorin, and cooling the solution by a medium out of contact therewith, whereby the tendency to produce metastannic compounds is avoided, substantially as described.

6. The herein-described method of making chlorin compounds of tin, which consists in subjecting a solvent for tin to the alternate and repeated action of metallic tin and a gaseous body containing chlorin, and cooling the solution by a medium out of contact therewith, whereby the tendency to produce metastannic compounds is avoided, substantially as described.



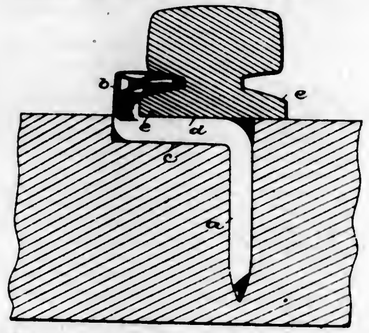
810,457. LAMP-BURNER. MARTIN O. ARNDERSON, Ivanhoe, Minn. Filed May 31, 1905. Serial No. 263,104.



Claim.—1. In a burner for lamps, the combination with a threaded portion arranged for engagement in the threaded collar of a lamp-body and having wick and air tubes extending therethrough, of a metallic tube secured at one end to the lower face of the threaded portion and depending therefrom and into which the wick and air tubes open, and a wick engaged in the wick-tube and extending through the depending tube, the lower portion of the wick being turned upwardly upon itself and inserted in the lower end of the depending tube.

2. In a burner for lamps, the combination with a central portion arranged for engagement of its lower end in the opening of a lamp-body and having wick and air tubes extending vertically therethrough, of a flattened tube secured at its upper end to the lower face of the central portion and depending therefrom and into which the wick and air tubes open, a wick disposed in the wick-tube and extending through the depending tube, the lower end of the wick being turned upwardly and tucked into the lower end of the depending tube, said wick being of a slightly lesser width than said tube and the wick-tube, and a wire inserted in the depending tube at one edge of the wick, the metal of said depending tube being crimped over the wire, said tube beyond the wire snugly fitting the wick.

810,458. RAILROAD-SPIKE. ROWLAND ANDERSON, Chihuahua, Mexico. Filed May 13, 1905. Serial No. 260,183.



Claim.—1. A railroad-spike having a stem or shank adapted to enter a cross-tie beneath the rail thereon, and a lateral extension of said stem forming a shoulder above which the rail is adapted to engage.

2. A railroad-spike having a stem or shank adapted to enter a cross-tie beneath the rail, a head adapted to engage over the edge of the flange of the rail, and a lateral extension of said stem connecting the same to the head and forming a shoulder above which the rail engages.

3. A railroad-spike having a head portion adapted to engage the flange of a rail, and a shank portion adapted to enter a cross-tie beneath the rail, said head and shank portions being connected by a shank extension or shoulder portion lateral to both said head and shank portions and above which shank extension the rail is adapted to engage.

4. A railroad-spike having a head portion adapted to engage the flange of a rail, and a shank portion adapted to enter a cross-tie beneath the rail, said head and shoulder portions being connected by a shank extension or shoulder portion approximately at right angles to both said head and shank portions and above which shank extension the rail is adapted to engage.

5. The combination with a flanged rail and a tie for supporting the same, of a railroad-spike having a head portion engaging above the rail-flange, a stem or shank portion penetrating downward into the tie beneath the rail, and a shank extension of said stem connecting the same to the head and passing transversely beneath the bottom surface of the rail, thereby forming a shoulder upon which the rail bears.

6. The combination with a flanged rail and a tie for supporting the same, of a railroad-spike having a head portion engaging above the rail-flange, a stem or shank portion penetrating downward into the tie approximately beneath the center of the rail, and a shank extension of said stem connecting the same to the head and passing transversely beneath the bottom surface of the rail, thereby forming a shoulder upon which the rail bears.

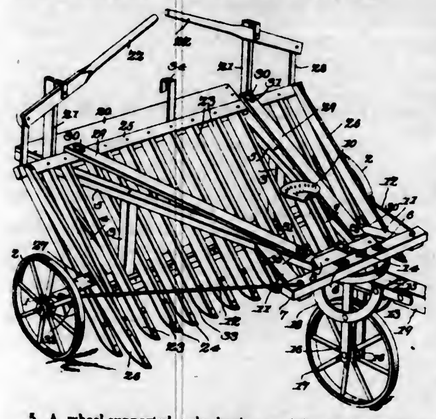
810,459. MANURE-SPREADER. JOHN M. BERINGER, Pomeroy, Wash. Filed Apr. 19, 1905. Serial No. 256,436.

Claim.—1. In a machine of the class described, a wheel-supported frame including uprights, braces, and side members, a spreader-head having teeth straddling the uprights of the frame, and bars loosely jointed with the side members of the frame and with the spreader-head and connecting the latter with the frame.

2. In a machine of the class described, a wheel-supported frame including an axle, uprights and side members, in combination with a spreader-head having teeth straddling the side members and the uprights and supported against the axle, and means movably connecting the spreader-head with the frame.

3. A wheel-supported axle having uprights and side frame members supported by said uprights, a spreader-head having teeth some of which straddle the side members and the uprights, and connecting-bars loosely connected with the spreader-head and with the side members of the frame.

4. A wheel-supported axle having uprights and side frame members supported by said uprights, a vertically-movable spreader-head having teeth engaging the front side of the axle and provided with a top cross-bar, and connecting-bars loosely connected with said top cross-bar and with the side members of the frame.



5. A wheel-supported axle having uprights and side frame members supported by said uprights, a vertically-movable spreader-head having teeth engaging the front side of the axle, connecting-bars loosely connecting the top of the spreader-head with the side bars of the frame near the front end of the latter, and a supporting-truck for the front end of the frame.

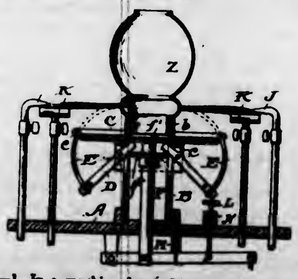
6. A wheel-supported frame, a spreader-head vertically movable in said frame, means for spacing the top of the spreader-head from the front end of the frame, a platform upon the frame, levers supported adjacent to said platform, links connecting the outer ends of said levers with the spreader-head, and a hook connected with the latter for engagement with the inner ends of the levers.

7. A wheel-supported frame, a spreader-head vertically movable in said frame, and means for spacing the top of the spreader-head from, and flexibly and slidably connecting it with the front end of the frame.

8. A wheel-supported frame, a spreader-head vertically movable with relation to said frame, spacing members connecting the top of the spreader-head flexibly and slidably with the frame near the front end of the latter, and means for independently manipulating the ends of the spreader-head.

9. A wheel-supported frame including an axle, uprights and side members supported upon said uprights, a vertically-movable spreader including teeth straddling the side members and the uprights, a wear-plate upon the front side of the axle, and shoes upon the points of the teeth of the spreader-head; said shoes having upward extensions engaging the wear-plate upon the axle.

810,460. MACHINE FOR MAKING AIR-HOLE GLASSWARE. FRANK H. BLACKBURN, Pontoria, Ohio, assignor to The National Electric Lamp Company, Cleveland, Ohio, a Corporation of New Jersey. Filed Feb. 24, 1905. Serial No. 247,161.



Claim.—1. In a machine for making air-hole glassware, the combination of means for holding the material, means for heating it in spots, and mechanism for engaging the material at such spots and then receding therefrom to draw out projections from the material.

2. In a machine for making air-hole glassware, the combination of means for holding the material, means for heating the same, in a plurality of places, members for simultaneously engaging the material at such plurality of places, and means for moving said members away from the body of the material.

3. In a machine for making air-hole glassware, the combination of a central support, a plurality of rods placed about the axis of the support and adapted to engage the globe at several points, means for heating the globe, means for simultaneously moving said rods toward the globe to strike it at the heated spots without puncturing the glass and for then retracting the rods with the glass clinging thereto.

4. In a machine for making air-hole glassware, the combination of means for holding a globe, means for directing a series of flames radially against it to heat separated spots thereon, a series of rods, and mechanism for causing them to move against the heated spots on the globe and then retreat.

5. In a machine for making air-hole glassware, the combination of a central support adapted to hold a glob, a series of rods arranged about the support and guided to move against the globe, means for so moving the rods and for causing them to move away from the globe, and means for heating the globe and the ends of the rods before they engage the globe.

6. In a machine for making air-hole glassware, the combination of a support for the globe, a series of gas-burners and air-jets arranged radially about the globe, a series of rods and mechanism for simultaneously moving them to engage the globe at the heated spots and for then moving them away from the globe to draw out horns from it.

7. In a machine for making air-hole glassware, the combination of a support for the globe, a series of heating members therefor, a series of rods, mechanism for simultaneously moving them to engage the globe at the heated spots and for then moving them away from the globe to draw out horns, and means for clearing the ends of the rods from glass tending to adhere thereto.

8. In a machine for making air-hole glassware, the combination of a support for the globe, means for directing a series of flames against the globe, a series of arc-shaped members located radially of the glassware, and means for swinging said members upward in vertical planes about the centers of their arcs to engage the glassware.

9. In a machine for making air-hole glassware, the combination of means for holding a globe, means for directing a series of flames radially against it, a series of rods, mechanism for causing them to move against the heated spots on the globe and then retreat, and means for causing said rods to pause during their forward movement with their forward ends in the flames whereby said ends become heated.

10. In a machine for making air-hole glassware, the combination of a tubular support for the globe, means for directing a series of flames against the globe, a series of levers pivotally carried by said support, a common operating-rod within said support and operatively connected with the inner ends of said levers, and rods operated by said levers and adapted to move against the globe and then away from it.

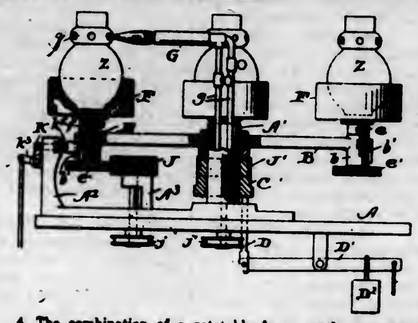
11. In a machine for making air-hole glassware, the combination of a support for the glassware, means for directing a series of flames against the glassware, a series of arc-shaped rods located about the glassware, means for swinging said rods about the centers of their arcs to engage the glassware, and a disk carried by the supports and having a series of openings guiding said rods.

810,461. MACHINE FOR GLAZING AIR-HOLE GLASSWARE. FRANK H. BLACKBURN, Pontoria, Ohio, assignor to The National Electric Lamp Company, Cleveland, Ohio, a Corporation of New Jersey. Filed Feb. 24, 1905. Serial No. 247,162.

Claim.—1 The combination of a rotatable support, globe-holders carried thereby, a heating-burner adapted to direct the flame against one of the globes, a glazing-burner adapted to direct a flame which comes substantially to a point against another of said globes, and means for adjusting such latter globe with reference to the flame whereby the flame will be caused to pass centrally through a hole in the globe.

2. The combination of a rotatable support, globe-holders carried thereby, a burner adapted to direct a glazing-flame which comes substantially to a point into an opening in a globe, means for frictionally driving the globe-holder in such position, and means for simultaneously raising or lowering such globe-holder to center the hole with reference to the flame.

3. The combination of a central standard, a support rotatably mounted thereon, a gas-burner, means for conducting gas and air thereto which extend upward through said standard, globe-holders carried by said support, whereby successive globes are brought into coöperation with the flame from said burner, each globe-holder being individually rotatable on its own axis.



4. The combination of a rotatable frame, sockets mounted therein, means for rotating said sockets on their individual axes in certain positions, globe-holders having stems frictionally engaging said sockets, a heating-burner adapted to coöperate with one of the globes, and a glazing-burner adapted to coöperate with another.

5. The combination of a rotatable frame, globe-holders each consisting of a recessed block with a stem, sockets carried by said frame adapted to receive said stem, pinions on said sockets, and means for engaging said pinions in a certain position to frictionally rotate the corresponding globe-holder, and a burner coöperating with the globe carried by such holder.

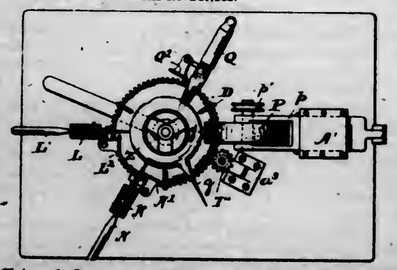
6. The combination of a rotatable frame, globe-holders each consisting of a recessed block with a stem, sockets carried by said frame adapted to receive said stem, pinions on said sockets, means for engaging said pinions in a certain position to frictionally rotate the globe-holders, a heating-burner and a glazing-burner coöperating with globes carried by said holders, and means for raising or lowering said frame to adjust the position of the globe being glazed.

7. The combination of a tubular standard, a frame rotatably journaled on the standard, means for raising or lowering the frame, gas and air pipes passing upward through the standard, a burner fed thereby and located above the rotatable frame and pointing outwardly, and individual globe-holders rotatably mounted on the frame.

8. The combination of a tubular standard, a collar slidable thereon, a rotatable frame journaled on the standard and resting on said collar, means for raising or lowering the collar, gas and air pipes passing upward through the standard, a burner fed thereby and located above the rotatable frame and pointing outwardly, individual globe-holders rotatably mounted on the frame, and means for frictionally rotating said globe-holders when in position to coöperate with said flame.

810,462. APPARATUS FOR MAKING AIR-HOLE GLASSWARE.

FRANK H. BLACKBURN, Fostoria, Ohio, assignor to The National Electric Lamp Company, Cleveland, Ohio, a Corporation of New Jersey.
Filed Feb. 24, 1905. Serial No. 247,163.



Claim.—1. In an apparatus for making air-hole glassware, the combination of a heater for the glassware, means for rotating the glassware, and means controlled according to such rotation for governing the heater.

2. In an apparatus for making air-hole glassware, the combination of means for rotating the glassware, a plurality of heaters adapted to act on the glassware, and means operating automatically with the rotation of the glassware to shut off said heaters successively.

3. In an apparatus for making air-hole glassware, the combination of a support for the glassware, a burner, means for rotating one with reference to the other, and automatically-operated means for shutting off the flame at predetermined positions of the glassware.

4. In an apparatus for making air-hole glassware, the combination of a plurality of burners placed radially about the glassware, means for rotating said glassware, shields for said burners, and means for moving them into and away from the flames from said burners.

5. In an apparatus for making air-hole glassware, the combination of a support for the glassware, heaters placed radially thereabout, shields for interrupting the flames from said heaters, means for rotating said support, and means controlled thereby for automatically operating said shields.

6. In an apparatus for making air-hole glassware, the combination of a burner, means for rotating the glassware, a shield for said burner, and mechanism for moving said shield into and out of the flame from said burner, said mechanism being controlled automatically according to the rotation of said support.

7. In an apparatus for making air-hole glassware, the combination of mechanism for rotating the glassware by successive steps, agencies to adapt it to coöperate with the glassware and placed radially about the same, and mechanism timed with respect to the rotation of the glassware for controlling said agencies.

8. In an apparatus for making air-hole glassware, the combination of a plurality of agencies located around the material to be acted upon and adapted to successively coöperate with said material, means for rotating the material, rotatable mechanism for governing said agencies, and means for rotating the same at a different speed from the material, whereby the material may be acted upon at a greater number of positions than that presented by one rotation thereof.

9. In an apparatus for making air-hole glassware, the combination of agencies to adapt it to coöperate with the glassware and placed radially about the same, means for rotating the glassware by successive steps, and mechanism governed by said means for controlling said agencies, said mechanism making a complete rotation at the same time that the glassware makes something more than a complete rotation, whereby the several agencies may act simultaneously around the glassware but will be prevented from acting on the finished holes.

10. In an apparatus for making air-hole glassware, the combination of mechanism for rotating the glassware by steps which amount each to an integral fraction of a complete rotation, a plurality of agencies placed around the glassware and adapted to coöperate with it at points whose distance apart correspond to a step or an integral multiple thereof, whereby as the glassware is rotated the spot which was acted upon by one agency comes into coöperation with another agency, and means governed according to said rotation for controlling said agencies.

11. In an apparatus for making air-hole glassware, the combination of a support for the glassware, mechanism for rotating said support by steps which amount to an integral fraction of a complete rotation, a plurality of agencies placed around the glassware and adapted to coöperate with it, and means governed according to said rotation for controlling said agencies, said means making a complete rotation while said support is making some steps more than a complete rotation, whereby on the second rotation of the glassware the agencies may not interfere with the completed portions thereof.

12. In an apparatus for making air-hole glassware, the combination of a support, means for rotating the same intermittently, a preliminary heater, an intense heater and a glazing-heater placed radially about the glassware on said support, whereby the same spot may be subjected successively to the three heaters, there being a position intermediate of the second heater and the glazer to allow the formation of a hole at the heated spot.

13. In an apparatus for making air-hole glassware, the combination of a heating-burner and a glazing-burner, means for rotating the glassware by successive steps to locate a given spot thereof in front of the heating-burner and later in front of the glazing-burner, an intermediate step leaving such spot in position to have a hole made through it.

14. In an apparatus for making air-hole glassware, the combination of a heating-burner and a glazing-burner, means for rotating the glassware by successive steps to position a given spot thereof in front of the heating-burner and later in front of the glazing-burner, an intermediate step leaving such spot in position to have a horn formed on it and broken off and the rough edge ground down, and means located for grinding such rough edge.

15. In an apparatus for making air-hole glassware, the combination of heaters and a grinder placed radially, and means for rotating the glassware on its axis to bring given spots successively to the action of the heaters and the grinder.

16. In an apparatus for making air-hole glassware, the combination of a support for the glassware, a heater and a grindstone placed radially about the same, means for rotating said support to bring a given spot on the glassware successively to said heater, then to a position where a horn may be formed on it, and then to said grindstone.

17. In an apparatus for making air-hole glassware, the combination of a ratchet mechanism for rotating the glassware step by step, a series of heaters placed about the glassware, cams for controlling said heaters, and means for operating said cams according to the rotation of the glassware.

18. In an apparatus for making air-hole glassware, the combination of means for intermittently rotating the glassware, a plurality of flame-producers placed radially about the glassware, individual shields adapted to interrupt such flames, cams for operating said shields mounted on a common support, and mechanism for rotating said cams at a definite rate in proportion to the rotation of the glassware.

19. In an apparatus for making air-hole glassware, the combination of means for rotating the glassware by steps which are each an integral fraction of a complete rotation, means for heating spots on said glassware, mechanism for controlling such means, said mechanism including cams connected with the glassware-rotating mechanism.

20. In an apparatus for making air-hole glassware, the combination of means for rotating the glassware by steps which are each an integral fraction of a complete rotation, means for heating spots on said glassware, mechanism for controlling such means including cams connected with the rotating mechanism and timed so that the rotating mechanism makes at least two complete rotations minus one step when the cams make one complete rotation.

21. In an apparatus for making air-hole glassware, the combination of a support for the glassware, heaters coöperating therewith and placed radially about the glassware separated by angles of sixty degrees or a multiple thereof, means for rotating said support by steps of sixty degrees, cams for controlling said heaters, and mechanism for giving said cams one complete rotation when the support is given one and five-sixths rotations.

22. In an apparatus for making air-hole glassware, a support for the glassware, ratchet mechanism for rotating the same by steps, there being as many steps in a complete rotation as there are holes to be made in the glassware, burners for projecting flames against the glassware, means for controlling such flames, cams for operating said means, said cams being geared with said ratchet mechanism to make a complete rotation when the support is making at least one rotation and a fraction of a second rotation whose denominator is the number of holes to be in the finished product, and whose numerator is one less than the number of holes.

23. In an apparatus for making air-hole glassware, a rotatable chuck, means for opening and closing the same, means for rotating said chuck on its axis by intermittent movements to bring the glassware successively into coöperation with different characters of heaters, combined with radially-placed heaters of different characters.

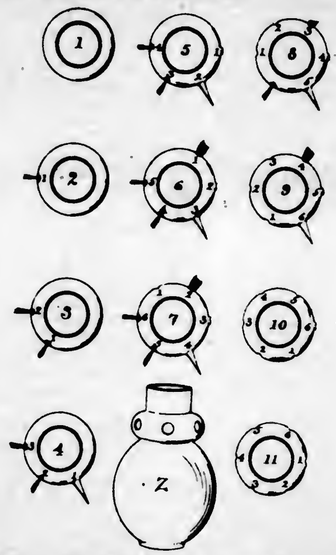
24. In an apparatus for making air-hole glassware, the combination of a support, means under the control of the operator for rotating the same intermittently, a heater, means automatically controlled by said rotation for governing said heater, a grinder, and means under the control of the operator for causing the same to engage the glassware.

25. In an apparatus for making air-hole glassware, the combination of a heating-burner, a glazing-burner, means for rotating the glassware on its axis by successive steps to locate a given spot thereof in front of the heating-burner, and later in front of the glazing-burner, there being means for causing said spot to stop temporarily in an unobstructed position between such burners where a hole may be made through it.

26. In an apparatus for making air-hole glassware the combination of a heating-burner, a glazing-burner, means for rotating the glassware on its axis by successive steps to locate a given spot thereof in front of the heating-burner, and later in front of the glazing-burner, there being means for causing said spot to stop temporarily in two positions intermediate of the burners, the first position allowing the formation of a horn on the glassware, and a grindstone at the second position.

810,463. PROCESS OF MAKING AIR-HOLE GLASSWARE.

FRANK H. BLACKBURN, Fostoria, Ohio, assignor to The National Electric Lamp Company, Cleveland, Ohio, a Corporation of New Jersey.
Filed Feb. 24, 1905. Serial No. 247,164.



Claim.—1. The process of making air-hole glassware consisting in heating a spot thereon, drawing out a horn from the outside of the ware at such a heated spot, removing said horn, grinding the rough edges, and glazing the hole.

2. The process of making air-hole glassware consisting of subjecting spots on the glassware successively to a preliminary heating, then an intense heating, then drawing out a horn on the outside of the ware at the heated spot, then breaking off said horn, then grinding the rough edges, and then glazing the hole.

3. The process of making air-hole glassware consisting of successively subjecting equidistant spots thereon to the action of a heating-flame, drawing out from the outside of the ware a horn or projection from the heated spots successively while the preceding spot is being heated, then removing the horn and grinding the rough edges and glazing the hole, said operations being performed one at one spot while another is going on at another spot.

4. The process of making air-hole glassware consisting in heating spots thereon, moving such spots away from the surrounding surface of the glassware to make horns, removing such horns, grinding the rough edges, and glazing the holes.

5. The process of making air-hole glassware consisting of successively subjecting equidistant spots thereon to the action of a heating-flame, forming a horn or projection from the heated spots successively while the preceding spot is being heated, then removing the horn and grinding the rough edges, said operations being performed one at one spot while another is going on at another spot.

6. The process of making air-hole glassware consisting in heating a spot thereon, forming a projection at such heated spot, removing such projection and grinding the rough edge thereat.

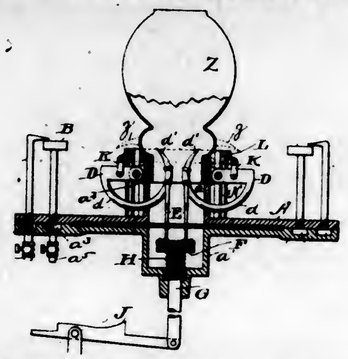
7. The process of making air-hole glassware consisting in subjecting spots on the glassware successively to a preliminary heating, then an intense heating, then forming a horn on the ware at the heated spot, then breaking off said horn, and then grinding the rough edges.

810,464. MACHINE FOR MAKING AIR-HOLE GLASSWARE.

FRANK H. BLACKBURN, Fostoria, Ohio, assignor to The National Electric Lamp Company, Cleveland, Ohio, a Corporation of New Jersey.
Filed Mar. 2, 1905. Serial No. 248,621.

Claim.—1. In a machine for making air-hole glassware, the

combination of means for holding the glassware, means for heating the same in a plurality of separated spots, and means for forcing such heated spots away from the adjacent surface of the glassware to make a horn which may be easily broken off to leave a hole.



2. In a machine for making air-hole glassware, the combination of means for holding the glassware, means for heating the same in a plurality of spots, mechanisms for engaging such heated spots on their inner sides and adapted to move outwardly to shove the spots outward in the form of horns, and means for simultaneously operating such mechanisms.

3. In a machine for making air-hole glassware, the combination of a series of movable members shaped to extend into the glassware, and common operating mechanism for moving said members outwardly to engage the glassware and press out horns thereon.

4. In a machine for making air-hole glassware, the combination of a standard adapted to hold the glassware, a series of rocking members projecting upwardly within the standard, means for heating the glassware, and means for rocking said members to cause their ends to engage the glassware and force out horns thereon.

5. In a machine for making air-hole glassware, the combination of a tubular standard adapted to receive at its upper end the glassware to be treated, a series of rocking members pivoted on the outer side of said standard and having arcual arms extended into the interior of the standard and adapted to point upwardly, mechanism for heating spots on the glassware which are in the path of said arms, and mechanism for rocking said arms to engage and force outwardly said spots.

6. In a machine for making air-hole glassware, in combination, a support for the glassware, a series of heaters arranged about the same and adapted to project flames against it, a series of rocking members having arcual arms, said members being pivotally carried about the support and normally having their arms projecting upwardly within it, and mechanism for rocking said members on their pivots to cause the points of their arms to engage the heated spots on the glassware and force the same outwardly to make horns thereon.

7. In a machine for making air-hole glassware, the combination of a series of movable members, mechanism for moving said members to engage the glassware and press horns thereon, and mechanism for engaging said horns to break them off.

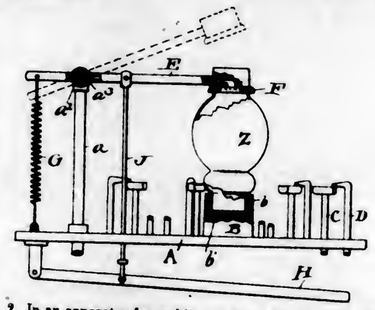
8. In a machine for making air-hole glassware, the combination of a series of rocking members, means for heating the glassware, means for rocking said members to cause their ends to engage the inner surface of the glassware and force out horns thereon, and correlatively-timed means for breaking off the horns.

9. In a machine for making air-hole glassware, the combination of a support for the glassware, a series of heaters arranged about the same and adapted to project flames against it, a series of pivoted rocking members having arcual arms, mechanism for rocking said members on their pivots to cause the points of their arms to engage the inner side of the heated spots on the glassware and force the same outwardly to make horns thereon, and mechanism operated on the return movement of said members to engage and break off said horns.

810,465. APPARATUS FOR MAKING AIR-HOLE GLASSWARE.

FRANK H. BLACKBURN, Fostoria, Ohio, assignor to The National Electric Lamp Company, Cleveland, Ohio, a Corporation of New Jersey. Filed Mar. 2, 1905. Serial No. 248,622.

Claim.—1. In an apparatus for making air-hole glassware, the combination of a support for the glassware, a series of flame-producers placed thereabout and immovable with reference to the support, and means for causing compressed air to pass into the interior of the glassware.



2. In an apparatus for making air-hole glassware, in combination, means for stationarily supporting the glassware, a series of flame-producers placed thereabout, a hood means for conveying compressed air thereto, and means for moving the hood into engagement with the glassware.

3. In an apparatus for making air-hole glassware, a support adapted to make an approximately air-tight connection with the glassware at its base, a series of flame-producers each adapted to project a point of flame against the glassware above such support, means adapted to tightly engage the upper end of the globe, said means having a passage-way for compressed air, and mechanism for operating said means.

4. In an apparatus for making air-hole glassware, the combination of means for engaging in approximately air-tight manner the ends of the ware, a compressed-air conduct leading through one of said means, and a series of flame-producers placed about the ware and adapted to project flames against the glassware in directions slightly out of the radial, whereby the air forcing outward and puncturing the heated glass will not blow out the flames.

5. In a machine for making air-hole glassware, a support for the glassware lined with asbestos to make a non-conducting and approximately air-tight connection with the glassware, means for heating the glassware simultaneously in a plurality of places above such support, and means for forming projections at the heated points of the glassware.

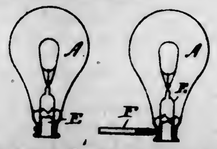
6. In an apparatus for making air-hole glassware, the combination of a support for the glassware, means for maintaining compressed air within the glassware, and means for heating a plurality of spots around the glassware, which spots are adapted to be forced outward by the compressed air.

7. In a machine for making air-hole glassware, the combination of means for engaging in a substantially air-tight manner the lower end of the glassware, a pivoted arm carrying a hood adapted to engage the upper end of the glassware, means for conducting compressed air to said hood, a spring tending to raise said arm, and means for lowering the arm to bring the hood into engagement with the glassware.

8. In an apparatus for making air-hole glassware, the combination of a support for the glassware, a series of flame-producers placed thereabout and adapted to project points of flame against the glassware above its lower edge to soften spots thereon, and means for conducting compressed air into the interior of the glassware.

810,466. PROCESS OF MAKING INCANDESCENT LAMPS.

FRANK H. BLACKBURN, Fostoria, Ohio, assignor to The National Electric Lamp Company, Cleveland, Ohio, a Corporation of New Jersey. Filed Mar. 2, 1905. Serial No. 248,623.



Claim.—1. The process of making incandescent lamps consisting in forming an opening into the globe substantially at the surface thereof, heating the neck of the globe to seal off the end thereof, then applying to such opening a tube separate from the globe and forcing pressure through the tube to blow off the end of the globe.

2. The process of making incandescent lamps consisting of taking a globe having an open neck, forming an opening into it without substantial projection thereat, sealing off by heat the neck of the globe, then applying to the opening a tube unsealed thereto, and by air-pressure through the tube blowing off the end of the globe to free it.

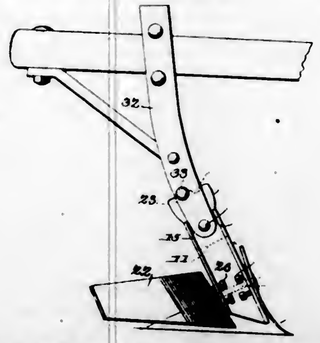
3. The process of making tipless incandescent lamps consisting in taking a globe having a neck, forming a small opening in it near the point where the neck joins the globe proper, sealing off by heat the neck of the globe just below such opening, then blowing air into the globe through such opening by means of a tube unsealed thereto the air blowing off the end of the neck.

4. The process of making tipless incandescent lamps consisting in taking a globe having a neck, forming a small opening into it near the point where the neck joins the globe proper, sealing off by heat the neck of the globe just below such opening, then blowing air into the globe through such opening by means of a tube unsealed thereto, the air blowing off the end of the neck, then placing the filament and its support in the globe, fusing the support to the globe below such opening, and then fusing a tube to the opening.

5. The process of making incandescent lamps consisting in forming a small hole in the neck, fusing off the surplus neck and sealing together the edges of that part which is not removed, blowing a puff of air into said hole through a tube which is independent of the bulb, sealing in the mount, and sealing an exhausting-tube to the neck over the aforesaid hole.

810,467. PLOW ATTACHMENT.

SAMUEL H. CLARK, Ringgold, Tex. Filed Feb. 7, 1905. Serial No. 244,605.



Claim.—1. A plow-foot having lateral flanges at the front and rear sides and with transversely-disposed threaded apertures through the flanges, a furrow-opener movably connected to the forward side of said foot member and a coverer member connected movably to the rear side of said foot member, set-screws operating in the threaded apertures of the forward flanges and bearing against said furrow-opener, set-screws operating through the threaded apertures of said rear flanges and bearing against said coverer member.

2. A plow-foot having a longitudinal aperture extending from front to rear and with lateral flanges at the front and rear provided with transverse threaded apertures therethrough, a furrow-opener and a coverer member disposed respectively at opposite sides of said foot member, a clamp-bolt connecting said furrow-opener and coverer member and extending through said longitudinal aperture, set-screws operating in one set of said threaded apertures for bearing against said furrow-opener, and set-screws operating through the other set of said threaded apertures and bearing against said coverer member.

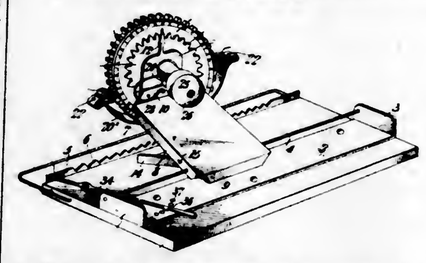
3. A plow-standard, a foot member having lateral flanges at the front and rear with transversely-disposed threaded apertures therethrough, means for connecting said foot member to swing upon said standard, means for coupling said foot member adjustably to said standard, a furrow-opener and a coverer member movably connected respectively to the opposite faces of said foot member, and set-screws operating through said threaded apertures for bearing respectively upon said furrow-opener and coverer member.

4. A plow-standard, a foot member having lateral flanges at the front and rear and with transversely-disposed threaded apertures therethrough and pivoted to swing from said standard, said foot member having spaced transverse recesses at its upper end, a stop-bolt carried by said standard for alternate engagement with said recesses whereby the foot member is connected adjustably to said standard, a furrow-opener and a coverer member movably connected respectively to the opposite faces of said foot member, and set-screws operating through said threaded apertures for bearing, respectively upon said furrow-opener and coverer member.

5. A plow-standard, a foot member pivoted to swing from said standard and provided with spaced transverse recesses, a stop-bolt carried by said standard for alternate engagement with said recesses, a furrow-opener and a coverer member connected to the opposite faces of said foot member.

810,468. MARKING-MACHINE.

GEORGE W. COFFMAN, St. Louis, Mo. Filed Apr. 15, 1904. Serial No. 203,369.



Claim.—1. In a marking-machine, a vibratory carriage supporting printing mechanism, a carriage-locking dog, and a spring operating to lift the carriage and actuate the dog.

2. In a marking-machine, a vibratory carriage supporting printing mechanism, a locking-dog combined therewith, and a spring operating to lift the carriage and to actuate the dog.

3. In a marking-machine, a vibratory carriage supporting printing mechanism, a carriage-locking dog pivotally combined therewith, and a spring having outward-diverging terminals to engage respectively with the carriage and with the dog.

4. In a marking-machine, a vibratory carriage supporting printing mechanism, a bar carried thereby, a carriage-locking dog hinged upon the bar, and a coiled spring mounted upon the bar and having its terminals bearing respectively against the under side of the carriage and the upper side of the locking-dog.

5. In a marking-machine, a track-bed, a carriage supported over the track-bed for longitudinal and vibratory movements, a flange carried by the rear end of the carriage, a locking-dog combined with the carriage, and a spring operating to actuate the locking-dog and to lift the carriage thereby to bring the flange into engagement with the track-bed to lock the carriage against movement.

6. In a marking-machine, a carriage provided with downturned flanges at its sides and one end, a bar passing through the side flanges, a locking-dog hinged upon the bar, and a spring having coils engaging the bar and its terminals in engagement with the under side of the carriage and the upper side of the dog, and operating normally to hold the dog and terminal flange in engagement with the base portion of the machine.

7. In a marking-machine, a vibratory carriage, a plate disposed at an angle thereto and provided with a slot and with a pointer, a type-wheel having its shank mounted in the slot, a type-centering and type-wheel-locking disk carried by the type-wheel, and a stud carried by the plate to engage with the disk to lock it against rotation.

8. In a marking-machine, the combination with a base of a vibratory carriage for supporting a type-wheel, a feed-rack combined with the base, a lever fulcrumed upon the base and having one end in engagement with the feed-rack to effect shifting thereof thus to vary the point of imprint of the type, and means for locking the lever at any desired adjustment.

9. In a marking-machine, a base a vibratory carriage combined therewith and supporting a type-wheel, a feed-rack combined for longitudinal movement with the base, and a lever fulcrumed upon the base and having one terminal in engagement with the feed-rack, and its other terminal furnished with an offset to interlock with suit-

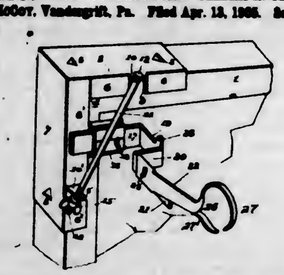
able orifices in the base to hold the feed-rack at any desired adjustment.

10. In a marking-machine, the combination with a vibratory carriage, of a plate provided near its upper portion with a slot, and near its lower portion with a trough provided with an orifice, a type-wheel carried by the plate and adapted to have its type projected through the orifice in the trough, a shield having an orifice registering with that of the trough, said shield being provided with flexible extensions, and yieldable inking-pads carried by the extensions.

11. In a marking-machine, the combination with a vibratory carriage, of a plate combined therewith and provided with a slot, a type-wheel having its shank projected through the slot and provided with an operating-knob, a spring carried by the plate and engaging the knob-shank and exerting upward pressure thereon, a type-centering and type-wheel-locking disk rigid with the type-wheel, and a stud carried by the plate to coact with the teeth of the disk to hold the type-wheel against rotation when its shank is moved to the lower end of the slot.

12. The combination with a base, of a track-bed, a track carried thereby, a vibratory carriage supported upon the track and provided with a stop coacting with the track-bed to limit the upward movement of the carriage, a spring-pressed dog combined with the carriage and coacting with the base to lock the former against lateral movement, a plate provided with a vertical slot, a printing element having a shank projected through the slot, a perforated shield disposed below the printing element and carrying inking mechanism, a stud carried by the plate, a toothed disk combined with the printing element and designed to engage the stud to lock the printing element against rotation during the printing operation, means for returning the printing element to its normal position after the printing operation, and means for returning the carriage to its normal position.

810,469. WINDOW-FIXTURE. CHARLES A. CRIBBS and HARRY R. McCOY, Vandergrift, Pa. Filed Apr. 13, 1905. Serial No. 255,307.



Claim.—1. A window-fixture, comprising an angular clamp adapted to embrace the corner of a frame, means for securing said clamp to said frame, embodying an angularly-disposed rod, a keeper carried by said clamp, a bracket adjustably mounted in said keeper and a curtain-supporting rod adjustably mounted on said bracket.

2. In a window-fixture, an angular clamp adapted to embrace the corner of a window or like frame, and having brads to impinge with the said frame, means engaging the angularly-extending portions of said clamp for binding the same on the frame, a keeper carried by said clamp, a bracket adjustably mounted in said keeper, and a curtain-supporting arm adjustably mounted on said bracket.

810,470. FOUNTAIN-BRUSH. ELIJAH C. DAVEY, Chicago, Ill. Filed Apr. 16, 1903. Serial No. 152,312.

Claim.—1. In a fountain-brush, a reservoir having an air-inlet and an outlet for its contents, the latter being arranged adjacent to the bristles, an outwardly-unseating valve controlling said outlet, an inwardly-unseating valve closing the air-inlet, and an air-pump arranged to supply air to said air-inlet.

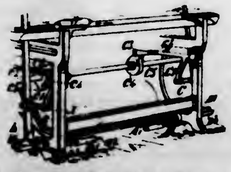
2. In a fountain-brush, a hollow handle, a reservoir arranged therein having an air-inlet and an outlet for its contents, the latter being arranged adjacent to the bristles, an outwardly-unseating valve controlling said outlet, an inwardly-unseating valve closing the air-inlet, an air-chamber in said handle adjacent to the air-inlet of the reservoir, and a piston movable in said air-chamber and operable from the exterior of the handle.

3. In a fountain-brush, a hollow handle, a reservoir arranged therein having an air-inlet and an outlet for its contents, the latter being arranged adjacent to the bristles, an outwardly-unseating valve controlling said outlet, an inwardly-unseating valve closing the air-inlet, an air-chamber adjacent to the air-inlet of the reservoir, a piston movable in said chamber, and a thumb-piece movable upon the exterior of the handle for operating said piston.

4. In a fountain-brush, a hollow handle, a reservoir arranged therein having an air-inlet and an outlet for its contents, the latter being arranged adjacent to the bristles, an outwardly-unseating valve controlling said outlet, an inwardly-unseating valve closing the air-inlets, springs holding said valves normally seated, an air-chamber arranged in the handle adjacent to the air-inlet of the reservoir, a piston movable in said chamber, a rod for said piston, a laterally-extending pin carried by said rod projecting through and movable in a slot in the wall of the handle, a thumb-piece carried by the projecting end of the pin, and a spring for returning the piston to its normal position after it has been operated.

5. A fountain-brush comprising a hollow handle having a reservoir therein provided with an air-inlet and outlet, an air-chamber adjacent to the air-inlet, a piston movable in said chamber, and means for operating said piston, substantially as specified.

810,471. LOOM. HERBERT W. DAVIS, Fall River, Mass. Filed Dec. 23, 1904. Serial No. 238,065.



Claim.—1. In a loom, a picker-stick having movement to throw a shuttle across the loom and mechanism for operating the picker-stick to throw the shuttle; means whereby such picker-stick is maintained normally in position intermediate its inward and outward limits of movement, such picker-stick being unopposed and being free to move for a distance in either direction from such normal position; and means acting after the beginning of the inward movement of such picker-stick to restrain the same, such means tending to return the picker-stick to its normal inactive position.

2. In a loom, a picker-stick; driving mechanism operating the picker-stick to throw a shuttle; and means whereby a force opposing that of the driving mechanism is offered to the picker-stick after the driving mechanism has begun to operate the picker-stick; restrains the inward movement of the picker-stick; and causes the picker-stick to move part way to its outward position, where it receives the impact of an incasing shuttle to move the picker-stick to its outward position.

3. In a loom, a picker-stick; driving mechanism operating the picker-stick to throw a shuttle; and means whereby a force, increasing in strength, opposes the movement of the picker-stick after the driving mechanism has ceased to act upon the picker-stick, and, with decreasing strength causes the picker-stick to return to a position between the extreme limits of its travel, to receive the impact of an incasing shuttle, the picker-stick being free to be moved by the shuttle into its extreme outward position, to be acted on by the driving mechanism.

4. In a loom, a picker-stick; driving mechanism operating the picker-stick to throw a shuttle; and means whereby a force, with increasing strength, opposes the movement of the picker-stick after the driving mechanism has ceased to act upon the picker-stick, and causes, with decreasing strength, the picker-stick to return to a position between the limits of its travel; said driving mechanism and said restraining means being so adjusted in relation to the picker-stick that neither of them opposes the operation of the other, and yet each permits the picker-stick to occupy freely a position between the extreme limits of its travel, and, upon receiving the impact of the incasing shuttle, to be moved to its extreme outward position, to be acted upon by the driving mechanism.

5. In a loom, a picker-stick; driving mechanism operating the picker-stick to throw a shuttle; and a spring operatively connected with the picker-stick, and opposing the movement of the picker-stick after the driving mechanism has ceased to act upon the picker-stick, and causing the picker-stick to return to a position between the extreme limits of its travel, to receive the impact of an incasing shuttle, which in turn, moves the picker-stick freely to its extreme outer position, to be acted upon by the driving mechanism.

6. In a loom, a picker-stick; driving mechanism operating the picker-stick to throw a shuttle; and a spring operatively connected with the picker-stick and opposing, by compression, the movement of the picker-stick, after the driving mechanism has ceased to act upon the picker-stick, and causing, by expansion, the picker-stick to return to a position between the extreme limits of its travel, to receive the impact of an incasing shuttle, the picker-stick being free to be moved by the shuttle into its extreme outward position, to be acted upon by the driving mechanism.

7. In a loom, a picker-stick; driving mechanism operating said picker-stick, during a portion of the pick; a spring, a draw-bar, an adjusting-nut threaded therein, all combined with a shell or guide fixed to the loom, and operatively connected to the picker-stick, to oppose by compression of the spring, the movement of the picker-stick after the driving mechanism has ceased to act upon the picker-stick, and to cause by expansion, the picker-stick to return to a position between the extreme limits of its travel to receive the impact of an incasing shuttle, the picker-stick being free to be moved by the shuttle into its extreme outward position, to be acted upon by the driving mechanism.

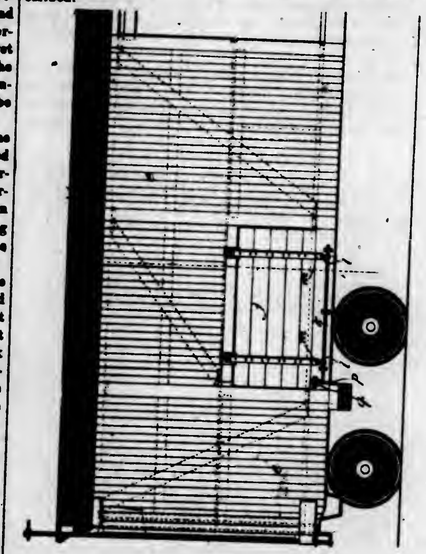
8. As an article of manufacture, a shell, or guide; a spring mounted therein; a draw-bar, axially arranged within the spring; a slot in said shell, parallel with the axis of the draw-bar; a threaded adjusting-nut engaging said draw-bar, and having a depending lug to engage said slot, whereby the nut may be locked to the bar.

810,472. BOX-CAR. FREDERICK A. DELANO, Chicago, Ill. Filed Mar. 26, 1903. Serial No. 149,627.

Claim.—1. In a box-car of the class described, the combination of a supporting-framework, side frames, end frames and a roof portion, a main central door in each side portion, and supplementary dumping-doors arranged on the inside and outside of each side frame between each end thereof and the main-door apertures depending metallic projections on the lower side of the outer dumping-doors, a rock-shaft on the car having projections engaging the depending metallic portions to lock the door, and means for holding the rock-shaft in locking position, substantially as described.

2. In a car of the class described, the combination of a supporting-framework, side frames and end frames extending upwardly therefrom and provided with a roof portion, main door at each side of the car at or near the central portion thereof, and swinging doors arranged in pairs on the inside and outside of each side frame extending downward to the floor-level when in closed position and adapted to be swung upwardly on the inside and outside depending metallic projections on the lower side of the outer dumping-doors, a rock-shaft on the car having projections engaging the depending metallic portions to lock the door, and means for holding the rock-shaft in locking position, respectively, substantially as described.

3. In a box-car of the class described, the combination of a supporting-framework, a rigid floor, rigid end boards, a roof, side frames having rigid portions extending from each roof to the floor, a main central door in each of such side frames extending substantially from the roof to the floor, supplementary vertical dumping-doors arranged in each side of the car between each end thereof and the main door swinging outward for automatically discharging a portion of the load and facilitating the discharge of the remainder thereof, depending metallic projections on the lower side of the outer dumping-doors, a rock-shaft on the car having projections engaging the depending metallic portions, to lock the door, and means for holding the rock-shaft in locking position and inner doors mounted adjacent to such dumping-doors swinging inward and resting against the rigid portion of the side frames when in closed position, substantially as described.



810,473. ADAPTER FOR INCANDESCENT-LAMP SOCKETS. SAMUEL B. DOANE, Cleveland, Ohio, assignor to The National Electric Lamp Company, Cleveland, Ohio, a Corporation of New Jersey. Filed Mar. 27, 1905. Serial No. 252,159.

Claim.—1. An adapter for incandescent lamps comprising a sleeve formed to engage a lamp-base and contact members carried thereby to engage the contacts of the socket, one of said members being rotatable independently of the other and accessible from within the sleeve and formed to allow the application of means within the sleeve for rotating such member when the sleeve is in the socket.

2. An adapter for incandescent-lamp sockets provided with a bushing adapted to fit over a post, and a sleeve adapted to receive the lamp-base, said sleeve and bushing being independently movable.

3. An adapter for incandescent-lamp sockets comprising a

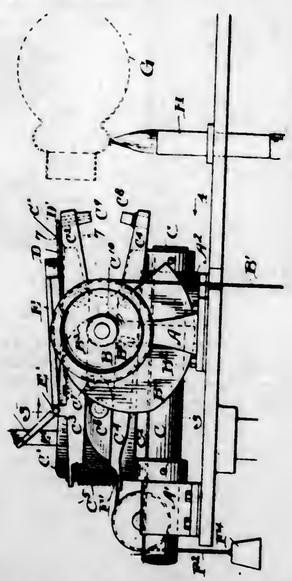
sleeve adapted to receive the lamp, a diaphragm within the end of the sleeve, an internally-threaded bushing supported by the diaphragm, the bushing and the sleeve being relatively movable, said bushing being formed on its outer face to allow the application of means for rotating the bushing.

4. An adapter for incandescent-lamp sockets comprising a sleeve adapted to receive the lamp and adapted to abut against a terminal ring within a lamp-socket, a diaphragm within the end of the sleeve and fixedly attached thereto, a bushing loosely supported by the diaphragm and adapted to be secured to a terminal post within the socket.

5. An adapter for incandescent-lamp sockets comprising a sleeve adapted to receive the lamp, a diaphragm within the end of the sleeve, an internally-threaded bushing supported by the diaphragm and rotatable and adapted to engage an externally-threaded terminal post within the socket, said bushing having a screw-driver slot across its upper surface.

6. In an adapter for incandescent-lamp sockets, an annular contact portion provided with a roughened surface adapted to bite into the metal of the terminal opposed thereto, and an independently-rotatable center member constituting the other terminal of the adapter.

810,474. MACHINE FOR PERFORATING GLASS. SAMUEL B. DOANE, Cleveland, Ohio, assignor to The National Electric Lamp Company, Cleveland, Ohio, a Corporation of New Jersey. Filed May 22, 1905. Serial No. 261,528.



Claim.—1. A process of perforating glass consisting in locally heating the same to a point of plasticity, attenuating and chilling a zone of the plastic glass, and striking a portion of the glass adjacent to said zone.

2. A process of perforating glass consisting in rendering it plastic, forming an attenuated annular zone and chilling the glass adjacent thereto and delivering a blow within the chilled attenuated zone.

3. A glass-perforating apparatus comprising means adapted to attenuate and chill the plastic glass, and means adapted to deliver a blow adjacent to the attenuated and chilled portion.

4. A machine for perforating glassware provided with perforating-jaws adapted to be advanced to operative position, means for causing each of said jaws to be advanced and means for automatically bringing the perforating-jaws together when so advanced.

5. A machine for perforating glass comprising two perforating members, one of which is equipped with a cutting edge, the other of which is provided with a face against which the cutting edge is adapted to bear, and a striking member adapted to deliver a blow to the glass.

6. A glass-perforating apparatus comprising two coöperative members, one of which is provided with an annular cutting edge, the other of which is provided with an annular surface against which the cutting edge is adapted to bear, a striking member within the annular bearing-surface and adapted to deliver a blow to the glass.

7. Mechanism for perforating glass, comprising means for holding the glass within a heating-flame, means for advancing a pair of perforating-jaws, and means for automatically bringing said jaws together as soon as they come within operative radius of the heated glass.

8. Mechanism for perforating glass comprising feeding means adapted to advance the glass to a heating-flame, means for automatically stopping said advancing movement, perforating-jaws adapted to be advanced toward the glass, and means for automatically bringing the jaws together when their advancing movement ceases.

9. Mechanism for perforating glass comprising jaws pivoted to a plate mounted on a reciprocative carriage, one of said jaws being provided with a cutting-annulus having an interior taper, the other of said jaws being provided with an annular bearing-surface for said cutting edge, and a striking member positioned within said annular bearing, and means for delivering a blow to said striking member.

10. A glass-perforating apparatus comprising jaws bearing perforating-annuli, means for causing said annuli to approach each other, and means for automatically delivering a blow to the glass inclosed by said annuli when they are brought together.

11. Glass-perforating mechanism comprising a frame-plate carrying a pair of pivoted perforating-jaws held apart at their perforating ends by spring means secured to their opposite ends, a double cam interposed between said jaws in such manner to bring the perforating ends of the jaws together when it is rotated, means for advancing the frame carrying the jaws, said advancing means being adapted to rotate the said cam.

12. A machine for perforating glass provided with two coöperating annuli adapted to outline a disk in the plastic glass, and means for automatically delivering a blow to the glass when said disk is outlined.

13. Means for perforating glass comprising a burner adapted to locally soften the glass, means adapted to advance the glass to said burner, means for automatically stopping said advance, means for advancing the perforating-jaws toward the glass and bringing them together, and means for automatically delivering a blow to the glass when said jaws are closed.

14. In a glass-perforating apparatus, a pair of perforating-jaws, means for holding the glass while being perforated, said latter means comprising a threaded shaft rotatable within a partially-threaded rotatable nut, and differential gears whereby the speed of the nut relatively to the shaft may be varied so as to be either greater or less than that of the shaft.

15. A machine for perforating glass comprising a carriage bearing perforating elements, means for retaining the carriage in a retracted position, means for retaining the perforating elements apart while the carriage is in such retracted position, means for advancing the carriage, and means for automatically bringing said perforating elements together on the termination of the advancing movement.

16. A machine for perforating glass comprising means adapted to form a thin chilled line in the glass when plastic, and means for automatically delivering a blow adjacent to said line upon the formation thereof.

17. A machine for perforating glass comprising unitary means adapted to excise a portion from the body of the glass and maintain all of said excised portion out of contact with the body of the glass.

18. A machine for perforating glass comprising means for exciding a portion therefrom when in a plastic state and automatic means for removing all of the excised portion clear of the body of the glass.

19. A process of perforating glass consisting in locally heating the same to a point of plasticity, attenuating and chilling a zone of the plastic glass and delivering a blow within the chilled attenuated zone of sufficient force to effect excision and drive the excised portion clear of the body of the glass.

810,475. BARRETTE-FASTENER. GEORGE W. DOVER, Cranston, R. I. Filed Aug. 25, 1905. Serial No. 275,763.

Claim.—1. In a fastener of the class described, the combination with the body and bearing-lugs, of a bar provided with a twisted flat integral lug upon one extremity, a socket upon the other end of the bar and disposed at right angles to said lug, a pivot-pin traversing the bearing-lugs and terminal lug, and a post upon the body adapted to engage the socket, as and for the purpose set forth.

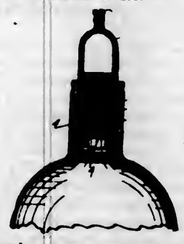
2. In a fastener of the class described, the combination with the body and bearing-lugs, of a spring-bar having a broad intermediate resilient portion, and provided with a flat integral twisted lug upon one extremity, a socket upon the other extremity, a pivot-pin traversing the bearing-lugs and terminal lug, and a post upon the body adapted to engage the socket, as and for the purpose set forth.

3. In a fastener, of the class described, the combination with the body and bearing-lugs, of a bar consisting of a strip of wire bent upon itself, the folded end comprising a flat lug, a cap upon the free ends of said wire, the two strands of the wire being separated to form a socket adjacent the cap, a pivot-pin traversing the bearing-lugs and terminal lug, and a post upon the body adapted to engage the socket, as and for the purpose set forth.

4. In a fastener of the class described, a body with bearing-lugs near one end and a post near the other end, and a bar bent upon itself with one end twisted in a plane at right angles to the body of the bar and formed into a flattened terminal lug, the other end of said bar formed with a socket between the strands thereof and intermediate said ends having its strands expanded to form an enlarged opening therebetween.

5. In a fastener of the class described, a curved body with bearing-lugs near one end and a post near the other end, and a bar bent upon itself with one end twisted in a plane at right angles to the body of the bar and formed into a flattened terminal lug, the other end of said bar formed with a socket between the strands thereof and intermediate said ends having its strands expanded to form an enlarged opening therebetween, said bar being curved longitudinally to conform to the curvature of the body.

810,476. CORK-EXTRACTOR. HERBERT H. DUNN, Dayton, Ohio. Filed May 1, 1905. Serial No. 258,188.



Claim.—1. A cork-extractor consisting of a metallic member incased throughout its length with packing material, the middle portion of said packing material being impervious to moisture, substantially as set forth.

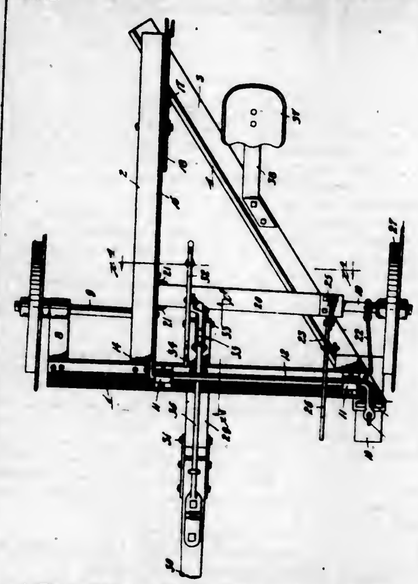
2. As a new article of manufacture, a combined cork-extractor and cork-retainer, consisting of a pliable metallic member adapted to span the lower end of the cord and to extend up the opposite sides of said cork, said member being inclosed in a casing, the portions of the casing lying at the sides of the cork and below the cork being impervious to moisture, and the extreme ends of said member being extended above the mouth of the bottle and carried down on opposite sides of the neck of the bottle, and means for securing said ends against the sides of the neck of the bottle, substantially as set forth.

810,477. ROAD GRADER AND DITCHER. CHARLES D. EDWARDS, Albert Lea, Minn. Filed June 24, 1905. Serial No. 266,005.

Claim.—1. In a grading-machine, the combination with a frame and a moldboard applied thereto, of a fixed axle projecting from one side of said frame, a floating axle pivotally connected to said frame and projecting at the other side thereof, wheels on said axle, and connection between said floating axle and said frame, whereby the weight of that side of the frame may be thrown onto the wheel of said floating axle, at will, substantially as described.

2. The combination with a triangular frame and a moldboard applied to the oblique side thereof, of a fixed axle projecting from one side of said frame, a floating axle hinged to said frame and projecting at the other side thereof, and flanged ground-wheels on said axles, substantially as described.

3. The combination with a triangular frame and a moldboard applied to the oblique side thereof, of a shoe applied at one corner portion of said frame, means for raising and lowering the frame of said shoe, a fixed axle projecting at the other side of said frame, a floating axle hinged to said frame and projecting at the landside thereof, wheels mounted on said axles, and a connection between said frame and floating axle for throwing the weight of that side of the frame onto the wheel of said floating axle, substantially as described.



4. The combination with a triangular frame and a moldboard applied to the oblique side thereof, of a pole hinged to the forward portion of said frame, and means for raising and lowering the rear portion of said frame, to vary the position of said moldboard with respect to a horizontal plane, substantially as described.

5. The combination with a triangular frame and a moldboard applied to the oblique side thereof, of a pole pivoted to the forward portion of said frame, a shoe and a wheel supporting the forward portion of said frame, and a connection between said frame and said pole, for raising and lowering the rear portion of said frame and moldboard, with a rocking action on said shoe and wheel, substantially as described.

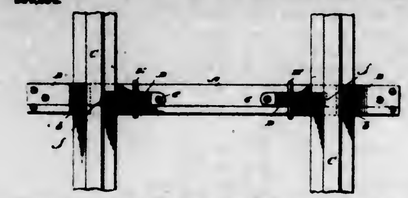
6. A grading-machine having a wheel arranged to resist side thrusts and mounted to move freely upward and downward with respect to its moldboard or scraper and without lifting the said moldboard or scraper from the ground, substantially as described.

7. In a grading-machine, the combination with a frame having a moldboard or scraper, of an axle extending across said moldboard, hinged at one end to said frame, and a wheel on the other end of said axle provided with projecting plates arranged to resist side thrusts, substantially as described.

810,478. LANDSIDE-WHEEL. CHARLES D. EDWARDS, Albert Lea, Minn. Filed June 24, 1905. Serial No. 266,006.

Claim.—A wheel having a hub 1, arms 2, rim 3 and an annular flange 4, said parts being cast integrally, and said flange 4 having the radial seats 5, of detachable thrust-resisting blades 6 lying in a common plane and a plurality of sharp-edged thrust-resisting blades fitting in said seats 5 and detachably held therein by nutted bolts 7, substantially as described.

810,479. RAILWAY. FRANK HUGLER, New Philadelphia, and ALBERT G. GUERNSEY, Uhrichsville, Ohio. Filed Oct. 24, 1905. Serial No. 284,304.



Claim.—1. In a railway, the combination of a tie, rail-braces fixed with respect to the tie, rails arranged on the tie and against said braces, locking-arms pivoted to the tie at the opposite sides of the rails, with reference to the braces, and arranged to engage the rails, and rings surrounding the tie and the locking-arms and slidable on and off the latter.

2. In a railway, the combination of a tie, rail-braces fixed with respect to the tie and provided with teats or projections, rails arranged on the tie and against the braces and having transverse openings receiving the teats or projections of the latter, locking-arms pivoted to the tie at the opposite sides of the rails, with reference to the braces, and having beveled ends arranged to engage the rails, and rings surrounding the tie and the locking-arms and slidable on and off the latter.

3. In a railway, the combination of a tie, a rail-brace carried by and fixed with respect to the tie, a rail arranged against the said brace, a locking-arm pivoted to the tie at the opposite side of the rail, with reference to the brace, and arranged to be swung into and out of engagement with the rail, and slidable means carried by the rail and engaging the arm for securing the latter in its working position.

4. A railway-tie having a rail-brace fixed with respect thereto and also having a rail-locking arm pivoted thereon, and a slidable ring surrounding the said arm and movable in the direction of the length thereof.

810,480. NON-REFILLABLE BOTTLE. JOHN M. GARDNER, St. Louis, Mo. Filed Nov. 26, 1904. Serial No. 234,103.

Claim.—1. A non-refillable bottle comprising a bottle-body provided with a neck, a valve in said neck, means to hold said valve in its seat except when the bottle is substantially inverted, a case closed at its upper end and secured to said neck and provided with openings in its side near its upper end, a cage in said case between said openings and said valve and provided with non-aligned openings.

2. An attachment for bottles comprising a case closed at its upper end and provided with lateral openings near its upper end and a cage in said case below said openings comprising diaphragms provided with non-aligned openings.

3. An attachment for bottles comprising a case closed at its upper end and provided with lateral openings near its upper end, a cap arranged to fit on the closed end of said case and close said openings, and a cage in said case below said openings provided with substantially parallel diaphragms corresponding in area to the area of the cross-section of said case and provided with non-aligned openings.

810,481. NON-REFILLABLE BOTTLE. WILLIAM H. GARNETT, Little Rock, Ark. Filed Aug. 31, 1905. Serial No. 276,269.

Claim.—1. A device of the character described comprising a casing provided with two chambers connected by a neck or contracted passage-way, the inlet for said casing being formed in one of said chambers, one of said chambers being provided with an overhanging bottom wall adjacent said neck, the outlet for said casing being formed in said bottom wall, a valve for the inlet, and means for holding said valve normally to its seat.

2. A device of the character described comprising a casing provided with two circular chambers of different diameters, connected by a neck or contracted passage-way, the smaller chamber being provided with an overhanging bottom wall, the inlet for said casing being formed in the larger chamber, the outlet therefor being formed in the bottom wall of the small chamber adjacent said neck, a valve for said inlet, and means for holding said valve normally to its seat.

3. A device of the character described comprising a casing formed of two chambers connected by an integral neck, the inlet for said casing being formed in one of said chambers in line with said neck, the other casing being provided with an overhanging bottom wall surrounding said neck and in which the outlet for said casing is formed, a valve for said inlet, and means for holding said valve normally to its seat.

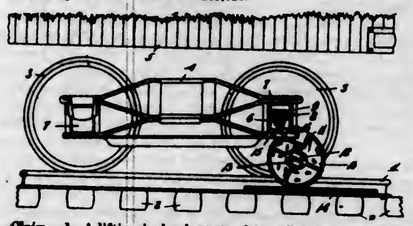
4. The combination with a bottle the neck of which is provided with an annular shoulder, of a casing formed of two chambers of different diameters united by a neck or contracted portion, the larger chamber resting upon said shoulder, the inlet for said casing being formed in the larger chamber and the outlet being formed in the smaller chamber, a valve for said inlet, and means for holding said valve normally to its seat.

5. The combination with a bottle the neck of which is provided with a plurality of holes or openings, of a casing located in said neck and formed of upper and lower communicating chambers, said casing being provided with an inlet and an outlet, rods or pins inserted through said openings and engaging the top wall of said lower chamber, a valve for said inlet, and means for holding said valve normally to its seat.

6. The combination with a bottle the neck of which is provided with an annular shoulder and an annular groove or offset the outer wall of which is provided with a plurality of holes or openings, of a casing resting upon said shoulder and formed of upper and lower communicating chambers, said casing being provided with an inlet and an outlet, rods or pins passed through said holes or openings and engaging the top wall of said lower chamber, a cement filling for said groove or offset, a valve for said inlet, and means for holding said valve normally to its seat.

7. The combination with a bottle the neck of which is provided with an annular shoulder, of a collar arranged adjacent said shoulder, a casing resting upon said shoulder and collar and formed of upper and lower communicating chambers, said casing being provided with an inlet and an outlet, means for locking said casing in position, a valve for said inlet provided with a depending stem, an arm or member depending from said collar, and a spring connecting said arm or member and said valve-stem.

810,482. LIFTING-JACK. GEORGE H. GILMAN, St. Paul, Minn. Filed July 14, 1905. Serial No. 269,726.

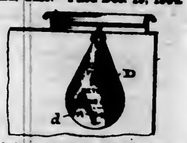


Claim.—1. A lifting-jack adapted to be applied between a journal-box of a car and the road-bed and constructed to frictionally engage with both thereof and arranged to lift the journal-box under a movement of the car, with a leverage action, and without slippage of any of the parts with respect to each other, substantially as described.

2. A lifting-jack of the character described, in the form of an eccentric wheel or disk adapted to be applied between the journal-box of a car and the road-bed, and arranged to roll and lift said journal-box, under a movement of the car, substantially as described.

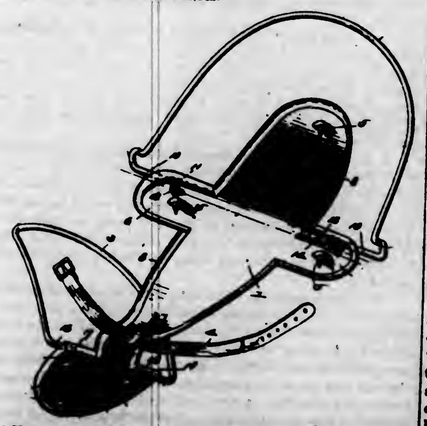
3. A lifting-jack in the form of an eccentric disk or wheel having in line with its minor axis, a projecting push-lug, as, and for the purposes specified.

810,483. VOUCHER FOR SHIPPING VESSELS. FREDERICK A. GILBERT, Cleveland, Ohio. Filed Dec. 19, 1904. Serial No. 237,490.



Claim.—A containing vessel provided with an opening, in combination with a closing device for said opening and a voucher detachably engaged with said closing device and of a size smaller in cross-section than said opening, whereby said voucher is confined within the vessel when the vessel is closed, and is removed therefrom with said closing device when the vessel is opened.

810,484. ICE-CREEPER. JOHN M. GRAY, Port Carbon, Pa. Filed Jan. 24, 1905. Serial No. 242,662.



Claim.—1. An ice-creeper comprising a sole-plate, and resilient loops disposed at the toe and heel portions thereof, and having their terminals permanently secured to the plate.

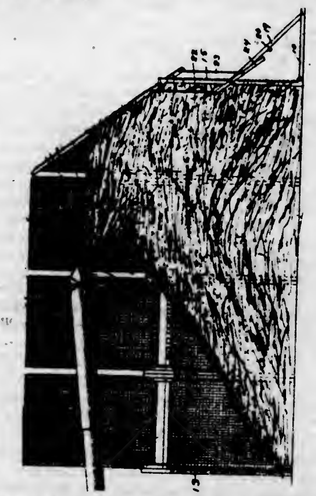
2. An ice-creeper comprising a sole-plate and resilient loops disposed at the toe and heel portions thereof, and having their terminals permanently secured to the plate, one of the terminals of each of the loops being adjustable relatively to the plate.

3. An ice-creeper comprising a sole-plate provided with a toe and heel portion, and with notched slots, and resilient loops each having one of its terminals rigidly secured to the plate, and its other terminal mounted for movement within one of the slots.

4. An ice-creeper comprising a sole-plate, and attaching-loops disposed at the toe and heel portions thereof, the toe-loop being provided with lateral shoulders or offsets to engage the sole of the shoe, and the terminals of the loops being permanently secured to the plate.

5. An ice-creeper comprising a sole-plate provided with lateral wings, and a heel-plate, calks carried by the plate, wings, and heel-plate, and resilient loops disposed at the toe and the heel portions of the plate, each having one of its terminals rigidly combined with the plate, and the other terminal adjustably connected therewith.

810,485. METHOD OF AND APPARATUS FOR STACKING STRAW. JOHN A. GUNN, Des Moines, and JOSEPH J. MCBRIDE, Leports, Iowa; said McBride assignor to said Gunn. Filed Nov. 20, 1904. Serial No. 234,262.



Claim.—1. The method of stacking straw which consists in first erecting a screen-barrier around the place upon which the stack is to be formed with the upper end portion of the barrier inclined toward the center of the place upon which the stack is to be formed, then depositing a quantity of straw within the barrier spaced apart from the barrier and finally discharging a blast of air ladened with straw downwardly and toward the barrier, said barrier retaining the straw and permitting the air to pass through and laying the straws adjacent to the barrier with their outer ends lower than their inner ends.

2. The method of stacking straw which consists in first erecting a screen-barrier then depositing a quantity of straw spaced apart from the barrier, then discharging a blast of air ladened with straw downwardly and toward the barrier and then directing the air-blast ladened with straw to different parts of the stack being formed to cause the straw to lie upon the stack with the outer ends of the straws lower than their inner ends.

3. The method of stacking straw which consists in first erecting a screen-barrier around the place upon which the stack is to be erected, said barrier having its upper portion inclined inwardly toward the center of the place upon which the stack is to be formed, then discharging a blast of air ladened with straw into the barrier in a direction tending to lay the straws within the barrier with their outer ends slightly lower than their inner ends, then directing the air-blast and straw to different parts of the stack to build up the stack with a greater quantity of straw upon its center than upon its edges.

4. The method of stacking straw which consists in discharging a blast of air ladened with straw in a nearly horizontal direction

against a screen-barrier which will permit parts of the straw to project through it and then removing the screen-barrier to permit the outer ends of the straws adjacent to the barrier to settle.

5. The method of stacking straw which consists in first erecting a screen-barrier with its upper end inclined inwardly, then discharging a blast of air ladened with straw against the barrier in a direction to lay the outer ends of the straws in a plane slightly lower than the inner ends and discharging the straw against the barrier in a manner to project portions of the straw through the barrier, and then removing the barrier, to form a stack with inclined sides and to permit the outer ends of the straws that were adjacent to the barrier to settle more than the inner ends, and to incline the straws on the exterior of the stack downwardly and outwardly for the purpose of shedding rain.

6. The method of stacking straw which consists in first erecting a screen-barrier and then discharging a blast of air ladened with straw toward the barrier, said barrier tending to retain the straw and permit the air to pass through it.

7. The method of stacking straw, which consists in first erecting a barrier, then discharging a blast of air ladened with straw toward the barrier, said barrier retaining the straw and permitting the blast of air to pass through and then removing the barrier.

8. The method of stacking straw which consists in first erecting a barrier, then arranging a chute adjacent to the barrier, then forcing a blast of air ladened with straw through the chute toward the barrier, said barrier retaining the straw and permitting the blast of air to pass through it and finally removing the barrier.

9. A stack-former comprising a screen-barrier member, means for supporting it in an upright position, a second screen-barrier member hinged to the top of the first capable of folding adjacent to the first and also of projecting upwardly above the first, and means for supporting it in its upwardly-projecting position.

10. A stack-former comprising a number of independent self-supported collapsible sections.

11. A stack-former comprising a number of screen-covered sections, each stack-forming section comprising an upright screen-covered frame and a screen-covered frame hinged to the upper end thereof capable of folding parallel with the upright frame and means for supporting it in an upwardly-inclined position.

12. A stack-forming section comprising a base portion and an upright portion hinged to the base portion and a top portion hinged to the upright portion and screens for covering the upright and top portions.

13. A stack-forming section comprising an upright screen-covered section member, an outwardly-projecting base member hinged to the bottom of the upright member and a top section member hinged to the upright section member and capable of folding from the position adjacent to the upright member inwardly and upwardly.

14. A stack-forming section comprising a base, an upright section member hinged to one end of the base and capable of lying parallel with the base, means for supporting the upright member in an upright position upon the base and a screen-covered top section member, hinged to the top of the upright section member, capable of folding parallel with the upright section member and means for swinging the top section member inwardly away from the base and upwardly.

15. A stack-forming section comprising a base, an upright section member hinged to one end of the base and capable of lying parallel with the base, means for supporting the upright member in an upright position upon the base and a screen-covered top section member, hinged to the top of the upright section member and means for swinging the top section member inwardly away from the base and upwardly, and means for locking the top section member in its upwardly-extended position.

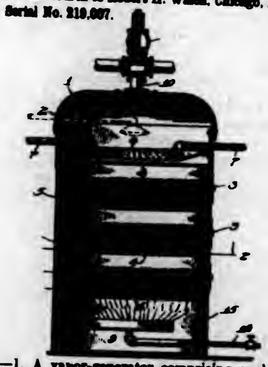
16. A straw-stack-former section comprising a base-frame, a screen-covered section member hinged to one end of the base-frame, arms provided with elbow-joints pivoted to the sides of the base member and the upright member, a top, screen-covered, section member hinged to the upper end of the upright section member, a lever pivoted to one side of the upright section member, rods connecting the lever and one side of the top section member for raising and lowering the top section member, means attached to the other side of the top section member and to the upright section member for locking said other side in its upright position.

17. A straw-stack-former section, comprising a base-frame, a screen-covered section member hinged to one end of the base-frame, arms provided with elbow-joints pivoted to the sides of the base member and the upright member, a top, screen-covered, section member hinged to the upper end of the upright section member, a lever pivoted to one side of the upright section member, rods connecting the lever and one side of the top section member for raising and lowering the top section member, means attached to the other side of the top section member and to the upright section member for locking said other side in its upright position, a rod attached to said lever, and means for adjustably securing it to the adjacent portion of the upright section member.

18. A straw-stack-former section comprising a base-frame, a screen-covered section member hinged to one end of the base-frame, arms provided with elbow-joints pivoted to the sides of the base member, a top screen-covered section member hinged to the upper end of the upright section member, a lever pivoted to the sides of the base member and the upright member, a top, screen-covered, section member hinged to the upper end of the upright section member, a lever pivoted to one side of the upright section member, rods connecting the lever and one side of the top section member for raising and lowering the top section member, means attached to the other side of the top section member and to the upright section member for locking said other side in its upright position, a rod attached to said lever, means for adjustably securing it to the adjacent portion of the upright section member and means for locking together the base and top section member when in their folded positions.

19. In a stack-former, a collapsible screen-barrier.

810,486. VAPOR-GENERATOR. AMOS HARRISON, Chicago, Ill., assignor of one-fourth to Robert H. Walsh, Chicago, Ill. Filed Aug. 1, 1904. Serial No. 219,607.



Claim.—1. A vapor-generator comprising a chamber, an incombustible porous body arranged within said chamber, and means for maintaining combustion within said chamber to heat said porous body, in combination with means for showering a liquid upon said heated body, and means for drawing off the steam and gases of combustion.

2. A vapor-generator comprising a chamber, an incombustible porous body arranged within the chamber, and means for continuously introducing material for supporting combustion into said chamber, whereby said porous body is heated to a suitable temperature, in combination with means for showering a liquid upon said porous body, and means for drawing off the commingled steam and gases of combustion.

3. A vapor-generator comprising an inclosing shell provided with a transverse vaporizing-partition dividing the shell into a vapor-dome above and a combustion-chamber below the same, a burner below the partition arranged to heat the same to a vaporizing temperature and means for permitting the products of combustion to pass to the vapor-dome, in combination with means for delivering a fluid to the vaporizing-partition and means for drawing off the resultant gases.

4. A vapor-generator comprising an inclosing shell provided with a transverse vaporizing-partition dividing the shell into a vapor-dome above and a combustion-chamber below the same, said combustion-chamber being open to atmospheric pressure, a burner arranged below the partition to heat the same to a vaporizing temperature, and means for permitting the products of combustion to pass to the vapor-dome, in combination with means for delivering a fluid to the vaporizing-partition and means for drawing off the resultant gases.

5. A vapor-generator comprising an inclosing shell provided with a transverse vaporizing-partition dividing the shell into a vapor-dome above and a combustion-chamber below the same, a burner below the partition arranged to heat the same to a vaporizing temperature and means for permitting the products of combustion to pass to the vapor-dome, in combination with means for delivering a fluid to the vaporizing-partition, a pipe for drawing off the commingled vapor and products of combustion, and a baffle-plate arranged before the entrance to said pipe.

6. A device of the kind described, comprising the combination of a suitable shell one or more porous vaporizing-bodies extending horizontally across said shell each consisting of a plurality of blocks of incombustible material, means for supporting the same, means for maintaining combustion within a portion of said shell to heat said blocks to a vaporizing temperature and means for thoroughly distributing a liquid upon the upper surface of the heated blocks, thereby producing a vapor within the shell composed of steam and the products of combustion.

7. A device of the kind described, comprising the combination of a shell provided with a covering of heat-insulating material one or more porous layers of incombustible material extending horizontally across said shell, a burner adapted to maintain combustion within said shell for heating said porous layers, means for distributing a liquid upon the upper surface of said heated porous layers thereby producing within the shell a heating medium composed of vapor mixed with the products of combustion.

8. A device of the kind described, comprising the combination of a shell provided with a covering of heat-insulating material, one or more layers of incombustible material extending horizontally across said shell, a burner adapted to maintain combustion within said shell for heating said layers, means for supplying said burner with a suitable combustible material, means for showering a liquid upon the upper surface of said heated layers thereby producing within the shell a heating medium composed of vapor mixed with the products of combustion.

9. A device of the kind described, comprising the combination of a suitable shell, one or more layers extending horizontally across said shell, each consisting of a plurality of blocks of incombustible material, means for supporting the same, means for maintaining combustion within said shell to heat said blocks, a foraminated trough arranged within said shell above said blocks adapted to shower a liquid discharged therein upon the upper surface of said heated blocks, thereby producing a vapor within the shell composed of steam and the products of combustion.

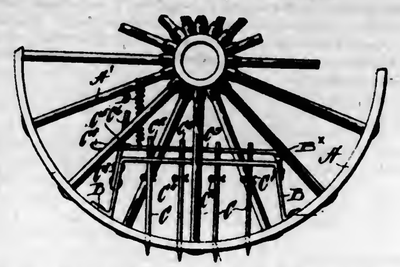
10. A device of the kind described, comprising the combination of a shell provided with a covering of heat-insulating material, one or more layers extending horizontally across said shell each layer consisting of a plurality of blocks of incombustible material, means for supporting the same, a burner adapted to maintain combustion within said shell for heating said blocks and means for supplying said burner with a suitable combustible material, a foraminated trough adapted to shower a liquid discharged therein upon the upper surface of said heated blocks, thereby producing a vapor within the shell composed of steam and the products of said combustion.

11. A device of the kind described, comprising the combination of a suitable shell provided with a covering of heat-insulating material, a discharge-pipe connected to said shell a baffle-plate arranged before the opening to said discharge-pipe, one or more layers of incombustible vaporizing material extending horizontally across said shell, a burner adapted to maintain combustion within said shell for heating said layers, and means for showering a liquid upon said heated layers, thereby producing a vapor within the shell composed of steam and the products of combustion.

12. A device of the kind described, comprising the combination of a suitable shell provided with a covering of heat-insulating material, a discharge-pipe connected to said shell, a baffle-plate arranged before the opening to said discharge-pipe, one or more layers extending horizontally across said shell each layer consisting of a plurality of blocks of incombustible vaporizing material, means for supporting the same, one or more burners adapted to maintain combustion within said shell for heating said blocks, means for supplying said burner with a suitable combustible material, a foraminated trough adapted to shower a liquid discharged therein upon the upper surface of said heated blocks, thereby producing a vapor within the shell composed of steam and the products of said combustion.

810,487. WHEEL FOR TRACTION-ENGINES. IRVIN O. HOSALUS, Crab Orchard, Nebr. Filed June 12, 1905. Serial No. 264,973.

Claim.—1. An attachment for wheels, comprising a bracket-plate adapted to be applied to the rim thereof, a series of spurs extending through said plate, and an operating-lever connected to each of said spurs and pivotally mounted upon said bracket.



2. An attachment for wheels, comprising a bracket-plate adapted to be applied to the rim thereof, a series of spurs extending through said plate, an operating-lever connected to each of said spurs and pivotally mounted upon said bracket, and a ratchet-bar carried at the opposite end of the bracket from the pivot of said lever.

3. An attachment for wheels, comprising a bracket-plate adapted to be applied to the rim thereof, a series of spurs extending through said plate, an operating-lever connected to each of said spurs and pivotally mounted upon said bracket, a ratchet-bar carried at the opposite end of the bracket from the pivot of said lever, and a retracting-spring extending from said lever to a relatively fixed portion of the wheel.

4. An attachment for wheels, comprising an apertured supporting-bracket, a series of spurs extending therethrough and through the wheel, eyes at the inner ends of said spurs, an operating-lever extending through said eyes, a pivotal lug carried by the bracket at one end of said operating-lever, a ratchet-tooth carried by said lever, and a coöperating ratchet-plate at the opposite end of said bracket.

5. An attachment for wheels, comprising an apertured supporting-bracket, a series of spurs extending therethrough and through the wheel, eyes at the inner ends of said spurs, an operating-lever extending through said eyes, a pivotal lug carried by the bracket at one end of said operating-lever, a ratchet-tooth carried by said lever, a coöperating ratchet-plate at the opposite end of said bracket, a stop projection carried by said spurs to engage the under face of said bracket, and a retracting-spring extending from said lever to a spoke of the wheel.

810,488. SHOVEL-GUARD. GEORGE W. JARVIS, Townsend, Mont. Filed Aug. 3, 1905. Serial No. 272,406.

Claim.—1. A shoe-guard for shovels comprising a tube split longitudinally to form a pair of inwardly-extending spring clamping-jaws having smooth continuous gripping-faces for engagement with the bit of the shovel.

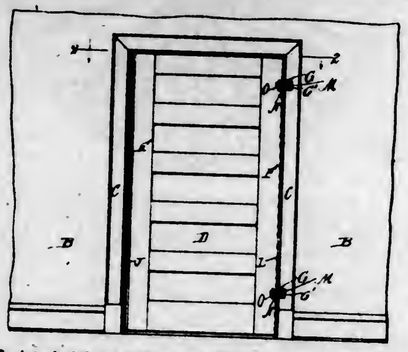
2. A shoe-guard for shovels comprising a cylindrical tube of uniform width split longitudinally to form a pair of parallel spring-jaws having smooth continuous gripping-faces for engagement with the bit of the shovel.

3. A shoe-guard for shovels comprising a reversible tube having curved exterior walls provided with a longitudinal slot defining a pair of inwardly-extending spring clamping-jaws the gripping-faces of which are smooth and continuous and adapted to engage the bit of the shovel, said gripping-faces being of equal length and disposed flush with the curved exterior walls of the tube.

810,489. GAGE FOR USE OF CARPENTERS AND JOINERS IN FITTING DOORS. JOHN A. JOHNSON, Chicago, Ill. Filed Apr. 5, 1905. Serial No. 253,933.

Claim.—1. A tool of the kind described, consisting of the several parts comprising the combination of a pair of stops, G, adapted to be attached to the stile of the door, and means for securing said stops to said door; each of said stops having a projecting shoulder-stop, I, and a shoulder-stop, K, said stops being adapted to fit the edge, B, and the face of a door-jamb, A; with a gage, P, having a

main part, Q, adapted at R to support a marker, F; and a marker, S, secured in the part, R, of the main body, Q, by screws, T; said main body, Q, being adapted to support a gage-bar, V, and a gage-bar, V, pivotally supported in said main part, Q, and means for adjustably securing said bar to said body; said bar, V, having curved points, V', near the ends of said bar; substantially as described and for the purposes specified.

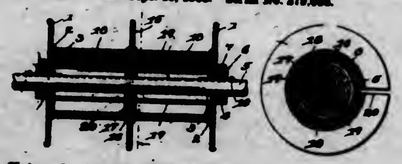


2. A tool of the kind described, consisting of the several parts described and forming the combination of a pair of stops, G, having shoulder-stops, I and K, and means for attaching said stops to the stile of a door; with a gage, P, having a main body, Q, adapted to support a marker, S, and gage-bar, V, and means for securing said marker and gage-bar to said body; a marker, S, adapted to be adjustably secured in said main body, and a gage-bar, V, adjustably secured to said main body; substantially as described and for the purposes specified.

3. A tool of the kind described, consisting of the several parts comprising the combination of a gage having a main body, Q, adapted to hold a marker, S, and a marker, S, adapted to be held in said main body, and means for adjustably securing said marker in said body; said main body, Q, being adapted to support a gage-bar, V; a gage-bar, V, supported in said main body, said bar having a curved bearing-point, V', near each end, the distance between said points being equal to the length of the marker, S; and means for adjusting said bar in said body in a position parallel with said marker, or at an angle thereto; with a pair of stops, G, having shoulder-stops, I and K, and means for attaching said stops to the stile of the door; substantially as described and for the purposes specified.

4. A tool of the kind described, consisting of the several parts comprising the combination of a gage having a main body, Q, adapted to hold a marker, S, and a gage-bar, V; and a marker, S, supported by said main body, and means for securing said marker to said main body; a gage-bar, V, supported in said main body, and means for adjustably securing the said bar to said body; with a pair of stops, G, having shoulder-stops, I and K, and means for attaching said stops to a door; substantially as described and for the purposes specified.

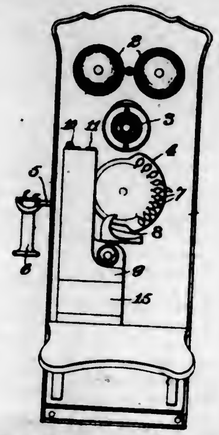
810,490. SAND-REEL. JACOB C. KNUPP and JAMES G. GREBER, Warren, Pa. Filed Sept. 13, 1905. Serial No. 278,093.



Claim.—1. A sand-reel including two heads each provided on its inner side with a pair of concentric annular flanges, said heads being provided with hubs having key-seats and set-screws disposed in registry with the key-seats; in combination with staves having their ends seated between the flanges of the heads, means for drawing the latter tightly in the direction of each other, a shaft extending through the hubs of the heads and having a longitudinal groove in alinement with the key-seats in the hubs, and keys or splines engaging said groove and key-seats and secured by the set-screws.

2. A sand-reel including a pair of heads, means for drawing said heads in the direction of each other, staves interposed between the heads and constituting the reel-body or drum, and an intermediate or auxiliary disk having a radial slot.

810,491. TELEPHONE TOLL APPARATUS. GEORGE A. LOUD, Hartford, Conn., assignor to The Gray Telephone Pay Station Company, Hartford, Conn., a Corporation of Connecticut. Filed Jan. 9, 1904. Serial No. 188,944.



Claim.—1. The combination with a set of telephone instruments including a receiver and a receiver-hook lever, of a toll-collecting device comprising a coin-channel, a coin-stop pivotally supported at its lower end forming a coin-pocket, independent plungers arranged at each side of said coin-pocket adapted to be connected through a coin deposited on the coin-stop to ring the bells at the called station, and operative connections between said coin-stop and said receiver-hook lever for rocking said coin-stop, substantially as described.

2. In a toll-collecting device for use with automatic telephones the combination with the telephone instrument including the switch-hook lever, of a casing having a coin-slot and a coin-channel communicating therewith, independent plungers arranged in axial alinement and located at the bottom of said coin-channel, a coin-stop closing the lower end of said coin-channel and located between and in operative relation to the opposing ends of the said plungers whereby a coin deposited on the said coin-stop will form a connection between the said plungers, and operative connections between said coin-stop and said switch-hook lever, substantially as described.

3. In a toll-collecting device for use with automatic telephone systems, the combination with the instrument including a switch-hook lever, of a casing having a coin-slot, and a channel registering with said coin-slot, independent plungers in axial alinement with their opposing ends located at each side of the channel, a pivotally-mounted coin-stop forming a bottom for the channel and arranged in operative relation to the plunger ends whereby a coin dropping through the channel is positioned on the coin-stop between the plunger ends, and means operated by the switch-hook lever for moving said coin-stop, substantially as described.

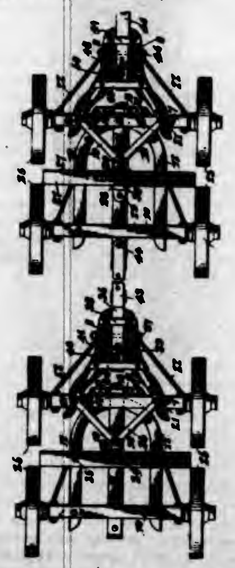
4. A toll-collecting device for use with automatic telephone systems comprising a casing having a coin-slot and coin-channel, independent plungers in axial alinement with their opposing ends located at each side of the coin-slot, and a pivotally-mounted coin-stop adapted in one position to close the bottom of said coin-channel and position a coin between the opposing ends of said plungers and in its other position to open the bottom of said coin-channel and discharge the coin, and actuating mechanism connected with said switch-hook lever for said coin-stop, substantially as described.

5. The combination with a set of telephone instruments including a receiver and receiver-hook lever, and the normally open contacts of the call-circuit, of a coin-channel operatively arranged with reference to said instruments, a pivotally-supported coin-stop forming a coin-pocket at the bottom of said channel, a plunger having one end in operative relation with said contacts and its other end arranged at one side of said coin-stop, a second plunger in axial alinement with said first plunger and having one end arranged on the opposite side of said coin-stop, its outer end being provided with a button, the parts being so arranged that a coin supported on said coin-stop forms a connection between said plungers whereby a pressure on the said button will move both of said plungers lengthwise to close said contacts, and operative connections between said coin-stop and said switch-hook lever to rock said coin-stop to discharge the coin from the channel.

6. The combination with an automatic telephone instrument including the receiver, the receiver-hook lever, and the normally open contacts for the call-circuit, of a toll-collecting device comprising a coin-channel, a coin-stop forming a bottom for the channel, the plungers in axial alinement with their opposing ends arranged at either side of said coin-stop, the opposite end of one of said plungers being in operative relation to said contacts, operative connections between said coin-stop and the receiver-hook lever, and a spring to move said mechanism when the receiver-hook lever is raised, substantially as described.

7. In a toll-collecting device for use with automatic telephones the combination with the telephone instrument including a switch-hook lever, of a casing having a coin-slot and a coin-channel communicating therewith and having a delivery-orifice, a coin-stop adapted to close said delivery-orifice and form a bottom for said slot, plungers having their opposing ends arranged in operative position at each side of said coin-stop whereby said plungers are connected for lateral movement, and means for moving said coin-stop to open said delivery-orifice and eject a coin.

810,492. VEHICLE. RANDOLPH H. MARTZ, Frederick, Md. Filed Aug. 19, 1905. Serial No. 274,896.



Claim.—1. In a vehicle of the class described, a truck comprising front and rear axles, a frame secured to one of the axles, a connection for the other axle pivoted to the frame between the axles, and means for limiting the swinging movement of the pivotally-connected axle, said means being adjustable to vary the limits of movement of said axle.

2. In a vehicle of the class described, a truck comprising front and rear axles, a frame secured to one of the axles, a connection for the other axle pivoted to the frame between the axles, and means detachably mounted on the swinging axle and movable into engagement with a portion of the frame to limit the swinging movement of the said pivotal axle.

3. In a vehicle of the class described, a truck comprising front and rear axles, a frame secured to one of the axles and having a portion transversely overlapping the other, a connection for said other axle pivoted to the frame between the axles, and a pin detachably and adjustably mounted in the swinging axle and engaging the overlapping portion of the frame to limit the swinging movement of said axle.

4. In a vehicle of the class described, a truck comprising front and rear axles, a bar rigidly affixed to one of the axles and transversely overlapping the other, a connection rigidly affixed to said other axle and pivoted to the bar, and pins carried by the swinging axle and located on opposite sides of the bar, said pins being adjustable toward and away from each other to vary the limits of the swing ing movement of the axle.

5. In a vehicle of the class described, a truck comprising a rear axle, a frame fixed to said rear axle and consisting of a central bar, and a truck-bound having side members secured to the rear axle on opposite sides of the bar, said bar extending in advance of the front end of the truck-bound, a front axle, rearwardly-extending braces connected to the front axle and pivoted to the bar in rear of its front end, said front axle swinging upon the bound and bar, and pins detachably carried by the front axle and located on opposite sides of the front end of the bar.

6. In a vehicle of the class described, a truck comprising axles, connections rigidly carried by the respective axles and pivoted to each other between the axles, the connection of one of the axles transversely overlapping the other axle and being longitudinally slidable upon the same, and means for limiting such sliding movement.

7. In a vehicle of the class described, the combination with an axle, of a bolster mounted on the axle, another axle, a frame carried by the other axle and having a portion disposed transversely of and slidable longitudinally with respect to the bolster, means pivotally connecting the axle and bolster to the frame, and means carried by the bolster for limiting the relative movement of the bolster and the portion of the frame associated therewith.

8. In a vehicle of the class described, the combination with an axle, of a bolster mounted on the axle in spaced relation thereto, another axle, connecting means carried by the other axle and having a portion sliding between the first-mentioned axle and bolster longitudinally of the same, and means connecting said axle and bolster for limiting such sliding movement.

9. In a vehicle of the class described, the combination with a front axle, of a bolster extending longitudinally thereof, fore hounds interposed between the axle and axle-bolster and separating the same a rear axle, a frame secured to the rear axle and including a bar that is slidable between the axle and bolster carried thereby, means connecting the front axle and bolster to the frame, and detachable devices connecting the front axle and bolster to limit the movement of the portion of the frame that is between them.

10. In a vehicle of the class described, the combination with a front axle, of a bolster rigidly secured thereto and spaced therefrom, a rear axle, a frame rigidly secured to the rear axle and comprising a truck-hound and bar, the front portions of which are slidable between the front axle and bolster, shoes carried by the truck-bound, wear-plates carried by the axle and bolster, and pins passing through the wear-plates and located on opposite sides of the frame-bar to limit the movement thereof.

11. In a vehicle of the class described, the combination with a truck, of a member pivoted to the truck, said truck member and being provided, one with a socket, the other with a locking device that is movable into the socket to hold the member against its pivotal movement.

12. In a vehicle of the class described, the combination with a truck, of a pole member pivoted to the truck and having an up-and-down swinging movement with respect to the truck, said truck and pole member being provided, one with a socket, the other with a movable locking device that is arranged to engage in the socket to hold the member against its pivotal movement.

13. In a vehicle of the class described, the combination with a truck having a socket, of a pole member pivoted to the truck and having an up-and-down swinging movement with respect thereto, and a locking device slidably mounted on the pole member and movable into the socket to hold the pole member against its swinging movement.

14. In a vehicle of the class described, the combination with a truck having forwardly-projecting spaced hounds, cross-bars connecting the hounds and forming a socket between them, a pole member pivoted to and between the hounds in advance of the socket, and a locking device slidably mounted on the rear end of the pole member and movable into and out of the socket.

15. An eight-wheeled wagon comprising separate four-wheeled trucks, each truck consisting of a front axle, a bolster, forwardly-extending hounds interposed between the axle and bolster, a rear truck, a frame rigidly secured to the rear truck and slidably mounted between the front axle and bolster, pivotal connections between the front axle and bolster and the frame, means connecting the front axle and

bolster to limit the swinging movement of the same, said means engaging the frame, and a truck-bolster mounted on the frame, a reach-pole pivoted between the bounds of the rear truck and connected to the front truck, means for limiting the swinging movement between the rear pole and rear truck, a tongue pivoted between the bounds of the front truck, and means for limiting the swinging movement of said tongue.

16. In a vehicle of the class described, a truck comprising front and rear axles, a frame connecting the axles, a truck-bolster pivotally mounted on the frame, and a rotary bearing for said bolster interposed between the same and the frame, said bearing comprising revolubly associated plates, one of which is provided with a curved recess, the other having a flange that turns in said recess.

810,493. RAIL-JOINT CHAIR. DANIEL HINSPELDER, Cincinnati, and WILLIAM L. HINSPELDER, Norwood, Ohio. Filed Oct. 26, 1905. Serial No. 284,374.

Claim.—1. In rail-end-alining means, a base-plate having rims on opposite edges to receive between them the base of two adjoining rail ends and wedges adapted to act against the under side of this plate to hold it against the under side of the rail ends.

2. In rail-end-alining means, the combination of a base-plate extending under both adjoining rail ends, and having inclined, wedge-engaging surfaces on its under side, wedges fitted to act against these surfaces, supports for these wedges and bolts to adjust them laterally on these supports with reference to the base-plate above.

3. In a rail-joint, the combination of rail-end-connecting means which are extended downwardly to form a closed housing, and rail-end-alining means contained in this housing.

4. In a rail-joint, the combination of rail-end-connecting means which are extended downwardly to form a closed housing, rail-end-alining means contained therein, bolts to adjust these means and a box on one side of this housing to permit access to these bolts.

5. In a rail-joint, the combination of rail-end-connecting means which are extended downwardly to form a closed housing, wedges in this housing, a base-plate between them and the rail ends above and means to act upon these wedges in a manner to hold the base-plate against both rail ends.

6. In rail-end-alining means, the combination of a base-plate below both rail ends, wedges adapted to act against the same from below, they being perforated to receive bolts for such purpose and supports for these wedges to hold them in opposition to their action against the base-plate above.

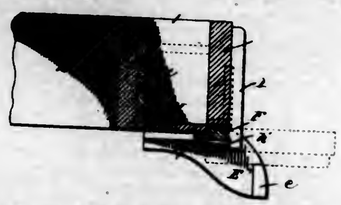
7. In a rail-joint, the combination of a housing, rail-alining means contained therein and tie-engaging attaching-flanges at opposite ends of this housing.

8. In a rail-joint, the combination of rail-end-connecting fish-plates which at their lower edges are extended outwardly and downwardly over the rail-base and inwardly again at some distance below the rail-base so as to form a housing thereat, bolts to connect these fish-plates to the rail ends, additional bolts to connect their extended parts below the rail-base which form the housing, a rail-end-alining base-plate with wedges under it contained in the housing mentioned and bolts to manipulate these wedges in a manner to cause them to hold the base-plate against the under side of the adjoining rail ends.

810,494. BLOCK-MOLD. JOHN C. MILLER, Jackson, Mich. Filed July 22, 1905. Serial No. 270,557.

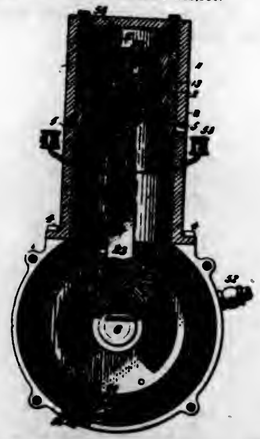
Claim.—1. A mold comprising a back plate and ends, a turning bar pivotally supported at the lower front corner of the mold and having spaced fingers extending therefrom, a removable pallet supported on the bar against the fingers, and forming the front side of the mold, and a face-plate secured to the bar and swinging between the ends and forming the bottom of the mold.

2. A mold comprising a back plate and ends, arms projecting forwardly from the ends and adjustable thereon, and having inwardly-projecting lugs, and a tilting front side and bottom pivoted between the arms and arranged to swing between the ends and down and out upon the lugs.



3. A multiple mold having a fixed back side and ends, division-plates projecting from the back between the ends, arms extending at the ends, and having inwardly-projecting lugs, a turning bar pivoted between the arms at the lower front corner of the mold and having projecting arms arranged to strike the lugs, a removable pallet supported upon the said projecting arms and forming the side of the mold, and a plurality of spaced face-plates secured to the bar and forming the bottom of the mold.

810,495. GAS-ENGINE. WILLIAM G. MILLER, West Medway, Mass. Filed Mar. 20, 1905. Serial No. 251,267.



Claim.—1. An engine comprising a casing, a piston reciprocally movable therein and dividing the casing into two compartments, one of said compartments forming the explosion-chamber, an inlet-valve to the other compartment, said piston adapted to draw the working agent into the said other compartment during one portion of its stroke, said casing having piston-controlled exhaust-ports for the explosion-chamber, means carried by the piston for passing the working agent into the explosion-chamber from the other chamber, and means carried by the piston for closing the exhaust-ports in advance of the admission of said working agent, substantially as shown and described.

2. An engine comprising a casing, a piston reciprocally movable therein and dividing the casing into two compartments, one of said compartments forming the explosion-chamber, an inlet-valve to the other compartment, said piston adapted to draw the working agent into the said other compartment during one portion of its stroke, said casing having piston-controlled exhaust-ports for the explosion-chamber, means carried by the piston for passing working agent into the explosion-chamber from the other chamber, means carried by the piston for closing the exhaust-port in advance of the admission of said working agent, and means mounted within the casing for automatically operating said first-mentioned piston-carried means.

3. An engine comprising a casing, a piston reciprocally movable therein, and dividing the casing into two compartments, one of said compartments forming the explosion-chamber, an inlet-valve to the other compartment, said piston adapted to draw the working agent into the said other compartment during one portion of its stroke, said casing having piston-controlled exhaust-ports for the explosion-chamber, means carried by the piston for passing working agent into the explosion-chamber from the other chamber, means carried by the piston for closing the exhaust-ports in advance of the admission of said working agent, and means mounted within the casing for automatically operating said piston-carried means.

4. An engine comprising a casing, a piston reciprocally movable therein and dividing the casing into two compartments, one of said compartments forming the explosion-chamber, an inlet-valve to the other compartment, said piston adapted to draw the working agent into said other compartment during one portion of its stroke, said casing having piston-controlled exhaust-ports for the explosion-chamber, means carried by the piston for passing working agent into the explosion-chamber from the other chamber, means carried by the piston for closing the exhaust-ports in advance of the admission of said working agent, and means mounted within the casing for automatically operating both of said piston-carried means.

5. In an engine of the character stated, a working cylinder and a crank-casing in communication with each other, a piston operatable in the working cylinder, a crank-shaft rotatably mounted in the crank-casing, a piston-rod connecting said crank-shaft with said piston, an intake-valve for said crank-casing, said piston arranged to draw working agent into said crank-casing when moving in one direction and to compress the working agent in the crank-casing when moving in the opposite direction, an inlet-valve in the piston-head for passing the working agent from the crank-casing into the explosion-chamber of the cylinder, said cylinder having exhaust-ports adapted to normally be closed by said piston and opened when the piston is at the limit of its stroke in one direction, and valve-controlling means carried by the piston, all being arranged substantially as shown and described.

6. In an engine of the character stated, a working cylinder and a crank-casing in communication with each other, a piston operatable in the working cylinder, a crank-shaft rotatably mounted in the crank-casing, a piston-rod connecting said crank-shaft with said piston, an intake-valve for said crank-casing, said piston arranged to draw working agent into said crank-casing when moving in one direction and to compress the agent in the crank-casing when moving in the opposite direction, an inlet-valve in the piston-head for passing the working agent from the crank-casing into the explosion-chamber of the cylinder, said cylinder having exhaust-ports adapted to be closed by said piston and opened when the piston is at the limit of its stroke in one direction, an exhaust-valve carried by the piston, means for automatically opening said inlet piston-valve, and means for automatically moving said exhaust-controlling valve to close the said exhaust-ports in advance of the opening of the inlet-valve.

7. In an engine of the character stated, a working cylinder and a crank-casing in communication with each other, a piston operatable in the working cylinder, a crank-shaft rotatably mounted in the crank-casing, a piston-rod connecting said crank-shaft with said piston, an intake-valve for said crank-casing, said piston arranged to draw working agent into said crank-casing when moving in one direction and to compress the working agent in the crank-casing when moving in its opposite direction, an inlet-valve in the piston-head for passing the working agent from the crank-casing into the explosion-chamber of the cylinder, said cylinder having exhaust-ports to be normally closed by said piston and opened when the piston is at the limit of its stroke in one direction, an exhaust-valve carried by the piston, means for automatically opening said inlet piston-valve, means for automatically moving said exhaust-controlling valve to close the exhaust-ports in advance of the opening of inlet-valve, and means for returning said inlet-valve to its seat.

8. In an engine of the character stated, a working cylinder and a crank-casing in communication with each other, a piston operatable in the working cylinder, a crank-shaft rotatably mounted in the crank-casing, a piston-rod connecting said crank-shaft with said piston, an intake-valve for said crank-casing, said piston arranged to draw working agent into said crank-casing when moving in one direction and to compress the agent in the crank-casing when moving in the opposite direction, an inlet-valve in the piston-head for passing the working agent from the crank-casing into the explosion-chamber of the cylinder, said cylinder having exhaust-ports adapted to be normally closed by said piston and opened when the piston is at the limit of its stroke in one direction, an exhaust-valve carried by the piston, means for automatically opening said inlet piston-valve, and means for automatically moving said exhaust-controlling valve to close the said exhaust-ports in advance of the opening of the inlet-valve, and means for returning said exhaust-controlling valve to its seat.

9. In an engine of the character stated, a working cylinder and a crank-casing in communication with each other, a piston operatable in the working cylinder, a crank-shaft rotatably mounted in the crank-casing, a piston-rod connecting said crank-shaft with said piston, an intake-valve for said crank-casing, said piston arranged to draw working agent into said crank-casing when moving in one direction and to compress the agent in the crank-casing when moving in the opposite direction, an inlet-valve in the piston-head for passing the working agent from the crank-casing into the explosion-chamber of the cylinder, said cylinder having exhaust-ports adapted to be closed by said piston and opened when the piston is at the limit of its stroke in one direction, an exhaust-valve carried by the piston, means for automatically opening said inlet piston-valve, means for automatically moving said exhaust-controlling valve to close the exhaust-ports in advance of the opening of the inlet-valve, and means for locking said exhaust-valve to its seat at times.

10. In an engine of the character stated, a working cylinder and a crank-casing in communication with each other, a piston operatable in the working cylinder, a crank-shaft rotatably mounted in the crank-casing, a piston-rod connecting said crank-shaft with said piston, an intake-valve for said crank-casing, said piston arranged to draw working agent into said crank-casing when moving in one direction and to compress the agent in the crank-casing when moving in the opposite direction, an inlet-valve in the piston-head for passing the working agent from the crank-casing into the explosion-chamber of the cylinder, said cylinder having exhaust-ports adapted to be closed by said piston and opened when the piston is at the limit of its stroke in one direction, an exhaust-valve carried by the piston, means for automatically opening said inlet piston-valve, and means for automatically moving said exhaust-controlling valve to close the said exhaust-ports in advance of the opening of the intake-valve, means for locking said exhaust-valve to its seat at times, and means for automatically releasing said locking means at times.

11. An engine comprising a working cylinder, a piston reciprocally mounted therein, said piston adapted to draw working agent into one end of said cylinder during one portion of its stroke and to compress said working agent on the return portion of its stroke, an inlet-valve in the piston-head adapted to open at predetermined times to admit said compressed working agent into the explosion-chamber of the cylinder, said cylinder having piston-controlled exhaust-ports substantially as shown and described.

12. An engine comprising a working cylinder, a piston reciprocally mounted therein, said piston adapted to draw working agent into one end of said cylinder during one portion of its stroke and to compress said working agent on the return of its stroke, an inlet-valve in the piston-head adapted to open at predetermined times to admit said compressed working agent into the explosion-chamber of the cylinder, said cylinder having piston-controlled exhaust-ports, and supplemental means carried by the piston for closing said exhaust-ports after the exploded mixture has escaped therethrough and before the opening of the piston inlet-valve.

13. In an engine of the class described, a working cylinder and a piston operatable therein, and an automatically-operated means carried by the piston for drawing oil into the cylinder to lubricate the moving parts, and an oil-containing vessel in communication with said cylinder substantially as shown and described.

14. In an engine of the class described, a working cylinder and a crank-casing, a piston reciprocally mounted in the working cylinder, a crank-shaft mounted in the crank-casing, a piston-rod connecting the crank-shaft to the piston, said piston having its head apertured and provided with a valve-seat, an inlet-valve carried by said piston with its stem passing through the piston-head, a valve-operating rod for said inlet-valve connected to its stem and held in bearings on the piston-rod, cam devices within the crank-casing for engaging said rod at times to open the valve, said cylinder having piston-controlled exhaust-ports, substantially as shown and described.

15. In an engine of the class described, a working cylinder and a crank-casing, a piston reciprocally mounted in the working cylinder, a crank-shaft mounted in the crank-casing, a piston-rod connecting the crank-shaft to the piston, said piston having its head apertured and provided with a valve-seat, an inlet-valve carried by said piston with its stem passing through the piston-head, a valve-operating rod for said inlet-valve connected to its stem and held in bearings on the piston-rod, cam devices within the crank-casing for engaging said rod at times to open the valve, said cylinder having piston-controlled exhaust-ports, and a supplemental valve carried by the piston for closing said exhaust-ports at times.

16. In an engine of the class described, a working cylinder and a crank-casing, a piston reciprocally mounted in the working cylin-

der, a crank-shaft mounted in the crank-casing, a piston-rod connecting the crank-shaft to the piston, said piston having its head apertured and provided with a valve-seat, an inlet-valve carried by said piston with its stem passing through the piston-head, a valve-operating rod for said inlet-valve connected to its stem and held in bearings on the piston-rod, cam devices within the crank-casing for engaging said rod at times to open the valve, said cylinder having piston-controlled exhaust-ports, and a supplemental valve carried by the piston for closing said exhaust-ports at times, and cam-controlled devices within the cylinder and crank-casing for positively operating said supplemental valve.

17. In an engine of the class described, a working cylinder and a crank-casing, a piston reciprocally mounted in the working cylinder, a crank-shaft mounted in the crank-casing, a piston-rod connecting the crank-shaft to the piston, said piston having its head apertured and provided with a valve-seat, an inlet-valve carried by said piston with its stem passing through the piston-head, a valve-operating rod for said inlet-valve connected to its stem and held in bearings on the piston-rod, cam devices within the crank-casing for engaging said rod at times to open the valve, said cylinder having piston-controlled exhaust-ports, a supplemental valve carried by the piston for closing said exhaust-ports at times, and cam-controlled devices within the cylinder and crank-casing for positively operating said supplemental valve in advance of the opening of the piston inlet-valve.

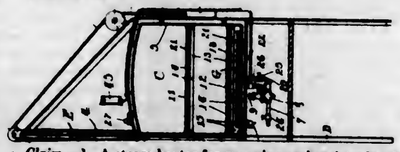
18. In an engine of the class described, a working cylinder and a crank-casing, a piston reciprocally mounted in the working cylinder, a crank-shaft mounted in the crank-casing, a piston-rod connecting the crank-shaft to the piston, said piston having its head apertured and provided with a valve-seat, an inlet-valve carried by said piston with its stem passing through the piston-head, a valve-operating rod for said inlet-valve connected to its stem and held in bearings on the rod, cam devices within the crank-casing for engaging said rod at times to open the valve, said cylinder having piston-controlled exhaust-ports, a supplemental valve carried by the piston for closing said exhaust-ports at times, cam-controlled devices within the cylinder and crank-casing for positively operating said supplemental valve in advance of the opening of the piston inlet-valve, means for locking said supplemental valve to its normal position and supplemental cam devices within the crank-casing for releasing said locking means at times.

19. In an engine of the character stated, a working cylinder, a crank-casing connected to one end thereof, a hollow piston, closed at one end, reciprocally mounted within the working cylinder, said working cylinder having exhaust-ports adapted to be closed at times by said piston, a crank-shaft mounted in said crank-casing, a piston-rod connecting said crank-shaft to said piston, said piston having its closed end formed of reduced diameter to provide an annular seat, said piston having its closed end provided with apertures and a valve-seat, an inlet-valve having a hollow stem projected through said piston-head and adapted to normally seat on said valve-seat in the piston-head, a tubular rod mounted in bearings on the piston-rod and having one end in engagement with said tubular stem of the piston-head valve, said tubular rod having a cam-engaging foot at its free end, a supplemental valve having an annular ring adapted to seat in said annular seat of the piston and having a stem passing through the hollow stem of the first-mentioned piston-valve, a second rod held within said first-mentioned rod and having one end connected to said stem of the supplemental valve and having its free end provided with a cam-engaging heel, cams mounted within said crank-casing for coöperating with the heels of said rods, a gear mounted on said crank-shaft, a pinion connected with said cams and said gear whereby the motion of the crank-shaft is imparted to the cams, said cams being so arranged as to operate said supplemental valve in advance of said first-mentioned piston-valve to close the exhaust-ports of the working cylinder in advance of the admission of a new charge of working agent into the explosion-chamber, and oil-containing vessels communicating with the interior of said working cylinder at a point in alinement with the juncture between the large and reduced portions of the piston so that when the supplemental valve is operated the same will draw in a supply of oil from the oil-containers to lubricate the moving parts within the working cylinder and crank-casing, all being arranged substantially as shown and for the purposes described.

20. In an engine of the character stated, a working cylinder, a crank-casing connected to one end thereof, a hollow piston open at one end reciprocally mounted within the working cylinder, said working cylinder having exhaust-ports adapted to be closed at times by said piston, a crank-shaft mounted in said crank-casing, a piston-rod connecting said crank-shaft to said piston, said piston having its closed end formed of reduced diameter to provide an annular seat, said piston having its closed end provided with apertures and a valve-seat, an inlet-valve having a hollow stem projected through said piston-head and adapted to normally seat on said valve-seat in the piston-head, a tubular rod mounted in bearings on the piston-rod and having one end in engagement with the tubular stem of the piston-head valve, said tubular rod having a cam-engaging foot at its free end, a supplemental valve having an annular ring adapted to seat in said annular seat of the piston and having a stem passing through the hollow stem of the first-mentioned piston-valve, a second rod within said tubular rod, having one end connected to said stem of the supplemental valve and having its free end provided with a cam-engaging heel, cams mounted within said crank-casing for coöperating with the heels of said rods, a gear mounted in said crank-shaft, a pinion connected with said cams and said gear whereby the motion of the crank-shaft is imparted to the cams, said cams being so arranged as to operate said supplemental valve in advance of said first-mentioned piston-valve to close the exhaust-ports of the working cylinder in advance of the admission of a new charge of working agent into the explosion-chamber oil-containing vessels communicating with the interior of said working cylinder at a point in alinement with the juncture between the large and reduced portions of the piston so that when the supplemental valve is operated the same will draw in a supply of oil from the oil-containers to lubricate the moving parts within the working cylinder and crank-casing, a latch for coöperating with the first-mentioned tubular rod to hold the first-mentioned piston-valve to its seat, and a supplemental cam member for tripping said latch at times to release said latch from operative connection with the first-mentioned tubular rod, all being arranged substantially as shown and described.

21. An engine comprising a casing including a crank and a piston-chamber, a piston reciprocally movable in the piston-chamber, a crank-shaft mounted in bearings in the casing, a piston-rod connecting the piston with the crank-shaft, inlet-valves carried by the piston for passing the working agent into the explosion-chamber of the casing, a supplemental valve carried by the piston for closing the explosion-chamber exhaust-ports, means mounted within the casing for operating both piston-valves automatically, means for locking the exhaust-port-closing valve at times, and means for drawing oil into the casing to lubricate the moving parts.

810,496. STEAM-HEATER FOR WARMING AND MOISTENING FOODS. CHARLES J. MONFORT, St. Paul, Minn.; Alice Monfort Dunn administratrix of said Charles J. Monfort, deceased. Filed Jan. 9, 1904. Serial No. 188,261.



Claim.—1. A steam-heater for warming and moistening foods, consisting, in combination, of a jacketed inclosure provided with perforated inner walls, a sprayer in said inclosure, a pipe connecting with said sprayer and the jacket of said inclosure, a pressure-regulating valve connected with said pipe, and a frame for supporting said parts.

2. A steam-heater for warming and moistening foods, consisting, in combination, of an inclosure formed by a steam-jacket, a sprayer in said inclosure, a steam-pipe connecting with said jacket and sprayer, a pressure-regulating valve connected with said pipe, and a frame for supporting said parts.

3. A steam-heater for warming and moistening foods, consisting, in combination, of a jacketed inclosure provided with perforations in its inner walls for admitting steam into said inclosure, a sprayer in said inclosure, a pipe connected with said jacket and sprayer, a pressure-regulating valve connected with said pipe, a door in said inclosure, and a frame for supporting said parts.

4. A steam-heater for warming and moistening foods, consisting, in combination, of a jacketed inclosure, trays in said inclosure provided with openings therethrough, a sprayer below said trays, a pipe connected with said jacket and sprayer, a pressure-regulating valve connected with said pipe, and a door in said inclosure

5. A steam-heater for warming and moistening foods, consisting, in combination, of a jacketed inclosure provided with perforated inner walls for admitting steam into said inclosure, trays in said inclosure provided with openings therethrough, a sprayer below said trays, a pipe connected with said jacket and sprayer, a pressure-regulating valve connected with said pipe, a door in said inclosure, and a frame for supporting said parts.

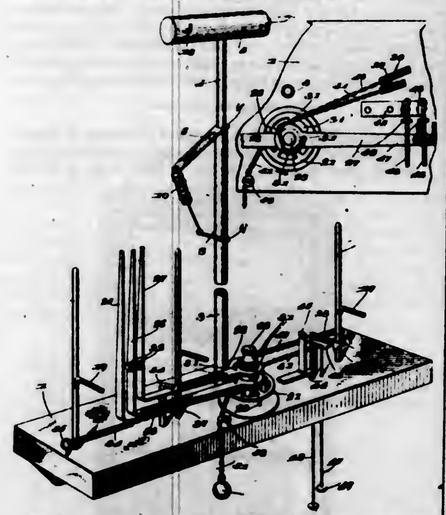
6. A steam-heater for warming and moistening foods, consisting, in combination, of a jacketed inclosure provided with perforated inner walls for admitting steam into said inclosure, a sprayer in said inclosure, a pipe connected with said jacket and sprayer, a pressure-regulating valve connected with said pipe, trays in said inclosure provided with openings, and distributing-cloths resting upon said trays.

7. A steam-heater for warming and moistening foods, consisting, in combination, of a jacketed inclosure provided with perforated inner walls for admitting steam into said inclosure, a sprayer in said inclosure, a steam-pipe connected with said jacket and sprayer, trays in said inclosure provided with openings, and cloths resting upon said trays.

8. A steam-heater for warming and moistening foods, consisting, in combination, of a jacketed inclosure provided with a perforated inner wall for admitting steam into said inclosure, a steam-pipe connected with said jacket, a pressure-regulating valve connected with said pipe, a tray in said inclosure provided with openings, a distributing-cloth resting upon said tray, and a door in said inclosure.

9. A steam-heater for warming and moistening foods, consisting, in combination, of a jacketed inclosure provided with perforated inner walls for admitting steam into said inclosure and with a vent through its floor, a sprayer in said inclosure, a steam-pipe connected with said jacket and sprayer, and a pressure-regulating valve connected with said pipe.

810,497. MUSIC-LEAF TURNER. FRANKLIN O. HOOKE, Los Angeles, Cal. Filed Nov. 21, 1904. Serial No. 233,709.



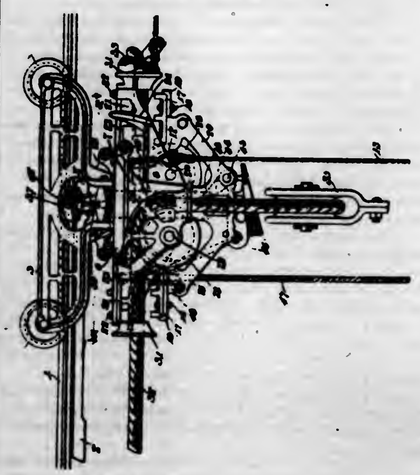
Claim.—1. A music-leaf turner comprising a base, a post rising therefrom, a series of leaf-turning members mounted to swing concentrically upon the post and progressing in length, a title-page holder mounted concentric with the leaf-turning members and having a concentric winding-reel, a guide carried by the base, a flexible element connected to the reel with its free end passing across the guide into an accessible position, the flexible element being wound upon the reel in a direction to swing the title-page holder from the left to the right when the flexible element is pulled across the guide, means tending to yieldably maintain the leaf-turning members at the left of the device, means for detachably holding all of the leaf-turning members at the right of the device, means for individually releasing the leaf-turning members, and means carried by the title-page holder for engagement with the leaf-turning members to swing the same from the left to the right.

2. A leaf-turner comprising a base, a post carried thereby, a swinging leaf-turning member having an opening loosely receiving the post and provided with a plurality of projections disposed in a concentric series around the opening, a spring connected to the base and having a flexible connection with one of the projections and exerting a tendency to yieldably maintain the leaf-turning member at the left of the device, said flexible connection being adapted to wrap around the series of projections when the leaf-turning member is swung to the right, means to removably hold the leaf-turning member at the right of the device, and means to release the leaf-turning member.

3. A music-leaf turner comprising a base, a post rising therefrom, a pair of superposed leaf-turning members mounted to swing about the post, the upper leaf-turning member having a reel rising therefrom around the post, the lower leaf-turning member having a pendent reel, springs connected to the base and connected respectively to the reels of the upper and lower leaf-turning members and exerting tendencies to maintain the leaf-turning members yieldably at the left of the device, means to detachably hold the upper leaf-turning member at the right of the device, means to release the upper leaf-turning member, and a flexible controlling element wound upon the reel of the lower leaf-turning member to swing the latter from the left to the right, said lower leaf-turning member having means for engagement with the upper leaf-turning member to swing the latter therewith from the left to the right into engagement with the holding means therefor.

4. A leaf-turner comprising a base, individual superposed leaf-turning members mounted to rotate concentrically upon the base and progressing in length from the uppermost to the lowermost member, a title-page holder mounted to rotate concentrically with the leaf-turning members below the lowermost member, the title-page holder having pendent projections disposed in a concentric series around the pivotal axis of the holder, each of the leaf-turning members being provided with upstanding projections disposed in a concentric series about its pivotal axis, springs connected to the right hand side of the base and flexibly connected to certain of the upstanding projections of the leaf-turning members with a tendency to yieldably maintain the latter at the left of the device and capable of winding about the projections when the leaf-turning members are turned from the left to the right, catches carried by the base and disposed to individually engage the leaf-turning members when swung to the right of the device, means for individually releasing the catches, a spring connected to the title-page holder and to the left-hand portion of the base, a guide carried by the base, and a flexible controlling element wound upon the pendent projections of the title-page holder and passing across the guide with its free end accessible for manipulation thereof to swing the title-page holder from the left to the right, said title-page holder having an upstanding projection for engagement with the leaf-turning members to swing the same from the left to the right.

810,498. HAY-CARRIER. PHILIP A. MYERS, Ashland, Ohio, assignor to F. B. Myers and Brother, Ashland, Ohio, a Copartnership. Filed Sept. 9, 1905. Serial No. 277,965.



Claim.—1. In a hay-carrier, the combination, with a track-carriage, and a carrier proper having a swiveled connection therewith, of means for locking the carrier proper and carriage against swiveling motion, said locking means acting to positively prevent rotation of the carrier proper in one direction and yielding to permit rotation in the opposite direction, substantially as described.

2. In a hay-carrier, the combination, with a track-carriage, and a carriage proper having a swiveled connection therewith, of means for locking the carrier proper and carriage against swiveling motion, said locking means comprising an automatically-acting bolt on one of said members and diametrically opposite recesses on the other member, said locking devices acting to positively prevent rotation of the carrier proper in one direction and yielding to permit rotation in the opposite direction, substantially as described.

3. In a hay-carrier, the combination, with a track-carriage, and a carrier proper having a swiveled connection therewith, of means for locking the carrier proper against swiveling movement relatively to the carriage, said means comprising an automatically-acting bolt carried by one of said members and engaging the other of said members, the engaged member being provided with diametrically opposite recesses, each having a positive stop-shoulder on one side and an inclined surface on the other side adapted to press back the bolt, substantially as described.

4. In a hay-carrier, the combination, with a track, a track-carriage, a carrier proper having a swiveling connection therewith, and a combined hoisting and traction rope supported by said carrier proper, of a spring-actuated locking-bolt mounted to slide vertically in one of said members and acting to engage the other member to lock it against swiveling, and an independent operating-rope connected to and depending from said bolt to permit its manual operation to disengage the same, substantially as described.

5. In a hay-carrier, the combination, with a track-carriage, and a carrier proper, the two connected by a swiveling connection comprising an annular flange on one of said members and a grooved flange to receive the same on the other member, said annular flange being provided at diametrically opposite points with locking-recesses, of a spring-actuated locking-bolt mounted on the other member and adapted to engage either one of said recesses, each of said recesses being provided on one side with a positive stop-shoulder and on the other side with an incline adapted to press back the bolt, substantially as described.

6. In a hay-carrier, the combination, with a track-carriage, and a carrier proper having a swiveling connection therewith, said carrier proper having rope connections which are laterally offset, of means for locking the carrier proper and carriage against swiveling motion, substantially as described.

7. In a hay-carrier, the combination, with a track-carriage, and a carrier proper having a swiveling connection therewith, said carrier proper having rope connections which are laterally offset, of means for locking the carrier proper and carriage against swiveling motion, said locking means acting to positively prevent rotation of the carrier proper in one direction and yielding to permit rotation in the opposite direction, substantially as described.

8. In a hay-carrier, the combination, with a track-carriage, and a carrier proper having rope connections which are laterally offset, of means for locking the carrier proper and carriage against swiveling motion, said locking means serving to positively prevent rotation of the carrier proper in the direction in which traction on the rope tends to rotate the same, substantially as described.

9. In a hay-carrier, the combination, with a track-carriage, and a carriage proper having a swiveling connection therewith, said carrier proper having rope connections which are laterally offset, of means for locking the carrier proper and carriage against swiveling motion, and means for manually disengaging said locking means, substantially as described.

10. In a hay-carrier, the combination, with a track-carriage, and a carrier proper having a swiveling connection therewith, said carrier proper having rope connections which are laterally offset, of means for locking the carrier proper and carriage against swiveling motion, said locking means comprising an automatically-actuated engaging bolt on one of said members and diametrically opposite engaging recesses on the other member, each recess provided with a positive stop-shoulder on one side and an incline on the opposite side adapted to press back the bolt, substantially as described.

11. In a hay-carrier, a frame provided with rope-supporting pulleys mounted on opposite sides thereof and located on opposite sides of a plane transverse to the body of the carrier, substantially as described.

12. In a hay-carrier, a frame provided with rope-supporting pulleys mounted on opposite sides thereof and located on opposite sides of a plane transverse to the body of the carrier, said carrier being provided with two sets of rope-gripping jaws alined with the respective pulleys, substantially as described.

13. In a hay-carrier, a frame comprising a fixed part and a movable part, and locking and tripping mechanism for holding in raised position and releasing said movable part, rope guiding and supporting pulleys mounted on opposite sides of said movable part and arranged on opposite sides of a plane transverse thereto, and two sets of rope-gripping jaws alined with the respective pulleys, one jaw of each set being fixed and carried by the fixed part of the frame, the other jaw being movable and actuated by the movable part of the frame, substantially as described.

14. In a hay-carrier, a frame comprising a fixed part and a movable part, and locking and tripping mechanism for holding in raised position and releasing the movable part, rope guiding and supporting pulleys mounted on the movable part on opposite sides thereof and also on opposite sides of a plane transverse thereto, and two sets of rope-gripping jaws alined with the respective pulleys, each set comprising a fixed jaw carried by the fixed part and a movable jaw carried by and moving with the movable part, substantially as described.

15. In a hay-carrier, the combination with a track-carriage, of a carrier proper having a swiveling connection therewith, and means for locking the parts against swiveling movement, said carrier proper comprising two rope guiding and supporting pulleys provided with alined gripping-jaws, located on opposite sides of said carrier proper and extending from the central portion thereof in opposite directions, substantially as described.

16. In a hay-carrier, the combination, with a track-carriage, of a carriage proper having a swiveling connection therewith, and means for locking said parts against swiveling movement, said carrier proper having a frame comprising a fixed and a movable part, rope guiding and supporting pulleys mounted on opposite sides of said movable part and lying on opposite sides of a plane transverse thereto, rope-gripping jaws alined with the respective pulleys and operated by the movement of the movable part of the carrier-frame, and means for lifting, holding in raised position and tripping said movable part of the carrier-frame, substantially as described.

810,499. **REFRIGERATOR.** CHARLEY MCDONNER, Manitowoc, Wis., assignor of one-third to Joseph J. Rosner and one-third to Charles Ahlgrim, Manitowoc, Wis. Filed Mar. 31, 1905. Serial No. 253,979.

Claim.—In a refrigerator, an ice box or chest composed of inner and outer shells constructed of sheet metal and spaced apart to provide an air-tight intervening cold-air space, a valved inlet for supplying the cold-air space with air under pressure, absorbent non-heat-conducting linings located within the said cold-air space and arranged on the said shells, and bars interposed between the shells and retaining the said linings in place and provided with openings to permit a circulation due to changes in temperature and also to enable the entire cold-air space to be charged with air under pressure.

810,500. **WAGON-BOLSTER.** GILBERT HOFFSTETTER, Clinton, Iowa. Filed June 26, 1905. Serial No. 267,422.

Claim.—In a device of the class described, a bolster having a recess in the lower face, a bearing member closely engaging said recess and provided with a central aperture a king-bolt, rotative in said aperture and with an enlarged head bearing upon said bearing member, an upper plate extending beneath said bolster and having an aperture for the passage of the king-bolt and with a collar around said aperture, and a lower plate supported upon the axle structure and provided with an aperture for receiving said collar.

810,501. **ELECTRIC FIRE-ALARM AND THERMO-INDICATOR.** ALFRED H. MCNEIL, Clapton, London, England, assignor to The Pearson Fire Alarm Limited, London, England. Filed May 1, 1905. Serial No. 258,373.

Claim.—1. In an electric fire-alarm in which an electric circuit is completed at a predetermined temperature by the deflection of a thermal strip, a box or chamber having an opening in one of its sides, an insulated contact-spring fixed inside the box and normally closing the said opening, an adjustable contact also mounted within the box in close proximity to the spring-contact, a thermal strip fixed at its ends outside the box, and a plunger attached to the thermal strip and arranged to project into the opening in the side of the box and to operate the contact-spring, substantially as described.

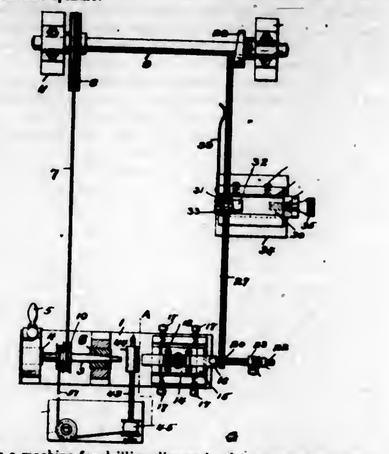
2. In an electric fire-alarm in which an electric circuit is completed at a predetermined temperature by the deflection of a thermal strip, a box or chamber provided with stuffing boxes or glands at its ends and an opening in one side, an insulating slab or support fixed inside the box, contacts mounted on the insulating-support, one of said contacts being adapted to close the opening in the side of the box, means for adjusting the other contact, electric leads or conductors connected to the contacts and passing through the stuffing-boxes, a thermal strip fixed at its ends outside the box, and a plunger on the strip adapted to enter the box through the opening in the side thereof and when the strip is deflected to the required degree to close the contacts and operate the alarm.

810,502. **CHECK-VALVE.** JOHN H. NOLAN and MOSES L. SANBORN, Boston, Mass., assignors to Boston Pneumatic Power Company, Boston, Mass., a Corporation of Maine. Filed July 18, 1904. Serial No. 216,933.

Claim.—A check-valve having a stem-plug provided with a duct extending therethrough having an inward-inclined upper edge forming a seat, a vertically-movable pin extending through the duct provided with a tapered head normally resting upon the plug-seat, a lug attached to the lower end of the pin, an annular rim on the stem-plug forming a tubular cavity, a flexible cap stretched over the upper portion of the stem-plug having its lower edge inserted within the cavity, said cap composed of two lips having parallel sides and whose outer ends are normally closed flat and permit gases to pass in only one direction, substantially as shown and described.

810,503. **DIAMOND-DRILL.** JOHN H. O'DONNELL, Waterbury, Conn., assignor to The Waterbury Wire Die Company, Waterbury, Conn., a Corporation of Connecticut. Filed Aug. 6, 1903. Serial No. 168,562.

Claim.—1. In a machine for drilling diamonds, the combination with a rotating spindle and a slide, for holding a drill and the diamond, of a spring for moving said slide in the direction of said spindle, for causing a yielding contact between said drill and diamond, and means in contact with said slide for moving the same away from said spindle.



2. In a machine for drilling diamonds, the combination with a rotating spindle and a slide, for holding a drill and the diamond, of a spring for moving said slide in the direction of said spindle, for causing a yielding contact between said drill and diamond, and positively-actuated means for moving said slide away from said spindle.

3. In a machine for drilling diamonds, the combination with a rotating spindle and a slide, for holding a drill and the diamond, of a spring for moving said slide in the direction of said spindle, for causing a yielding contact between said drill and diamond, a pivotally-mounted member engaging said slide, and means for actuating said pivotally-mounted member, whereby said slide will be moved against the tension of said spring.

4. In a machine for drilling diamonds, the combination with a rotating spindle and a slide, for holding a drill and the diamond, of a bow-spring for moving said slide in the direction of said spindle, for causing a yielding contact between said drill and diamond, a pivotally-mounted rod having frictional contact with said slide, and means for swinging said rod upon said pivot-mounting.

5. In a machine for drilling diamonds, the combination with a rotating spindle and a slide, for holding a drill and the diamond, of a spring for moving said slide in the direction of said spindle, for effecting a yielding contact between said drill and diamond, a pivotally-mounted rod contracting with said slide, and a cam for actuating said rod upon its pivot-mounting.

6. In a machine for drilling diamonds, the combination with a rotating spindle and a slide, for holding a drill and the diamond, of a spring for moving said slide in the direction of said spindle, for effecting a yielding contact between said drill and diamond, a pivotally-mounted rod engaging said slide at one end, a cam for actuating said rod upon its pivot-mounting, and means for yieldingly holding said rod in engagement with said cam.

7. In a machine for drilling diamonds, the combination with the spindle; of a slide; a spring for moving said slide in the direction of said spindle; a pivotally-mounted rod engaging said slide at one end; and means for shifting the position of said pivot-mounting.

8. In a machine for drilling diamonds, the combination with a spindle; of a slide 10; a spring 26 for moving the said slide in the direction of said spindle; means for shiftably securing said spring to said slide whereby the tension thereof may be varied; a rod 27 pivotally mounted between its ends and engaging a part upon said slide; a rotary cam; and a spring 39 for normally holding said rod against said cam.

9. In a machine for drilling diamonds, the combination with the spindle; of a slide; a bow-spring, one end of which is fixed and the other engaging said slide, for moving said slide in the direction of said spindle; means for connecting said spring to said slide under varying tensions and positively-actuated means for moving said slide in the opposite direction.

10. In a machine for drilling diamonds, the combination with the spindle; of a slide; a bow-spring, one end of which is fixed and the other engaging said slide, for moving said slide in the direction of said spindle; and means for shifting the position of the fixed end of said spring.

11. In a machine for drilling diamonds, the combination with the drill; of a slide having a plurality of shoulders upon one side thereof; and a spring for actuating said slide in one direction, said spring being arranged with one end fixed and the other to engage any of said shoulders.

12. In a machine for drilling diamonds, the combination with the drill; of a slide 16 having the notches 21 in one side thereof; of the flat spring 26; and the adjustable spring-blocks 23.

13. In a machine for drilling diamonds, the combination with a spindle; of a head member; a slide-rest; means for adjustably securing said slide-rest; a slide mounted within said slide-rest; a spring mechanism for moving said slide in the direction of said spindle; and means for connecting said spring to said slide under varying tensions.

14. In a machine for drilling diamonds, the combination with a spindle; of a head member having a recess therein; a slide-rest within said recess; means for adjusting said slide-rest within said recess; means for securing the same in any of its adjusted positions; a slide mounted within said slide-rest; spring mechanism for moving said slide in the direction of said spindle; and means for varying the tension of said spring.

15. In a machine for drilling diamonds, the combination with a head member; of a rotary spindle mounted therein carrying a drill or needle, a slide-rest adjustably secured to said head member; a slide movably mounted within said slide-rest; spring mechanism for moving said slide toward said spindle; means for varying the tension of said spring upon said slide; and positively-actuated means for moving the slide in the opposite direction.

16. In a machine for drilling diamonds, the combination of a rotating spindle, a slide having a projecting part thereon, the said spindle and slide adapted to hold a drill and the diamond, a spring for moving said slide in the direction of said spindle to effect a yielding contact between said drill and diamond, and a rod member and means for moving it in the path of said projecting part for moving the slide away from the spindle.

17. In a machine for drilling diamonds, the combination of a rotating spindle, a slide having a projecting part thereon, the said spindle and slide adapted to hold a drill and the diamond, a rod member and means for moving it in the path of said projecting part, and a spring for moving said slide in the direction of said spindle for effecting a yielding contact between the drill and the diamond, and holding said projecting part in contact with said rod member.

18. In a machine for drilling diamonds, the combination with the rotary spindle carrying a drill or needle; of means for sharpening said drill or needle, said means comprising a lap-roll; and means for rotating the same at an angle to said spindle, said means being actuated from said spindle.

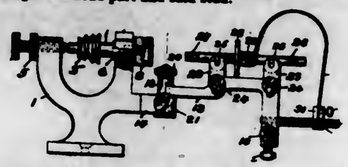
19. In a machine for drilling diamonds, the combination with the rotary spindle carrying a drill or needle; of means for sharpening said drill or needle; said means comprising an auxiliary spindle having a lap-roll thereon, supported at one end manually and the other in a fixed part; and a belt connecting a pulley upon said spindle with a pulley upon said auxiliary spindle.

20. In a machine for drilling diamonds, the combination with the rotary spindle 3 having a cone 10 thereon and carrying a drill or needle therein; of means for sharpening said drill or needle, said means comprising an auxiliary spindle 43 having a lap-roll 44 and pulley 45 thereon; a plate 42 forming a support for one end of said spindle; a rod 46 having the idler-pulleys 47 and 48 thereon; and the belt 51 connecting said cone 10 with said pulley 45.

810,504. DIAMOND-DRILL AND BURNISHING-LATHE. JOHN E. O'BRIEN, Waterbury, Conn., assignor to The Waterbury Wire Die Company, Waterbury, Conn., a Corporation of Connecticut. Filed Aug. 6, 1903. Serial No. 168,563.

Claim.—1. In a machine of the character described, the combination with a head member; of a spindle rotatable therein; a slide movable toward and away from said spindle; means for shifting the position of said slide laterally; and a spring for actuating said slide in the direction of said spindle.

2. In a machine of the character described, the combination with the head member; of a spindle rotatable therein; a bracket; means for securing the same to said head, whereby it may be shifted laterally or radially, said means comprising a stud passing through a part upon said head and a part upon said bracket, and a screw passing through said head part and said stud.



3. In a machine of the character described, the combination with the head member; of a spindle rotatable therein; a slide; rolls for forming a bearing for said slide; and means for adjusting the position of said rolls, whereby the relative position of said slide in relation to said spindle may be varied.

4. In a machine of the character described, the combination with a head member having a lug projecting therefrom; a bracket; means for adjustably and pivotally securing said bracket to said lug; a slide movably mounted upon said bracket; and a spring for actuating said slide in the direction of said head member.

5. In a machine of the character described, the combination with the head member; of a spindle rotatable therein; a slide, circular in cross-section, having an adjustable shoulder thereon; adjustable rolls forming a bearing for said slide; and spring mechanism for actuating said slide in one direction.

6. In a machine of the character described, the combination with the head member 1 having the lug 14 thereon; of the spindle 2 rotatable therein; a bracket 13; means for adjustably securing said bracket to said head member; a slide 26; blocks 23 adjustable within said bracket; and rolls 25 rotatably mounted in said blocks and forming a bearing for said slide.

810,505. GARMENT-SUPPORTER. BERTHA ORTELL, Newark, N. J. Filed Nov. 10, 1903. Serial No. 180,544.

Claim.—1. As a new article of manufacture, a garment-supporter comprising devices each adapted to receive the stud of a corset-steel, a strap secured to one of said devices and a strap secured to the other of said devices, the last-aforesaid strap passing adjustably through the first-aforesaid device.

2. As a new article of manufacture, a garment-supporter, comprising diverging straps, a device to which one of said straps is connected, a device to which the other strap is connected with the last-aforesaid strap passing adjustably through the first-aforesaid device, an extension integral with one of said straps, and means connected therewith for engaging the skirts or other garments to hold the same down and thereby secure the waist-line in position.

3. As a new article of manufacture, a garment-supporter, comprising plates each having a slot therein adapted to receive the stud of a corset-steel, a strap secured to one of said plates, and a strap secured to the other of said plates, the last-aforesaid strap passing adjustably through the first-aforesaid plate.

4. As a new article of manufacture, a garment-supporter, comprising plates each having a slot therein adapted to receive the stud of a corset-steel, a strap secured to one of said plates, a strap secured to the other of said plates with the last-aforesaid strap passing adjustably through the first-aforesaid plate, an extension integral with one of said straps, and means connected therewith for engaging the skirts or other garments to hold the same down and thereby secure the waist-line in position.

5. As a new article of manufacture, a garment-supporter, comprising two plates each having a slot adapted to receive the stud of a corset-steel, and an elongated slot at right angles to the aforesaid slot, a strap secured in the elongated slot of one plate and an adjustable strap passing through the last-aforesaid elongated slot, through the elongated slot in the other plate and secured therein and extending beyond the said slot.

6. As a new article of manufacture, a garment-supporter, comprising plates each having a slot therein adapted to receive the stud of a corset-steel, a strap secured in one of said plates, a strap secured in the other of said plates, the last-aforesaid strap passing adjustably through the first-aforesaid plate, other straps connected to the strap secured in the other of said plates at or about the point in which it is secured, a shield secured to said other straps, and straps connected to said shield and adapted to pass around the waist of the wearer.

7. As a new article of manufacture, a garment-supporter, comprising two plates each having a slot adapted to receive the stud of a corset-steel, and an elongated slot at right angles to the aforesaid slot, a strap secured in the elongated slot in one plate and an adjustable strap passing through the last-aforesaid elongated slot, through the elongated slot in the other plate and secured therein and extending beyond said slot, other straps secured to the last-aforesaid strap just above where the same passes through the slot in the last-aforesaid plate, means for holding down the skirts or other garments to secure the waist-line in position, a shield secured to said other straps, and straps connected to said shield and adapted to pass around the waist of the wearer.

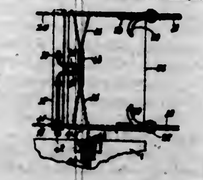
810,506. HEAD FOR JACK-SPOOLS, WARP-BEAMS, OR THE LIKE. SUMNER T. PACKARD, Brockton, Mass. Filed Dec. 8, 1904. Serial No. 235,963.

Claim.—1. A removable end for a jack-spool or the like constructed of a laminated, fibrous, grainless material and having means near the periphery thereof for binding together the individual laminæ.

2. A removable end for a jack-spool or the like consisting of a disk composed of a laminated, fibrous, grainless material and having a plurality of rivets adjacent the periphery thereof.

3. A removable end for a jack-spool or the like consisting of a plurality of united flax-fiber disks provided with a central opening and peripheral strengthening means.

810,507. WATER-MOTOR. RICHARD K. PARKINSON, Ruing, New Zealand. Filed Sept. 3, 1904. Serial No. 223,288.

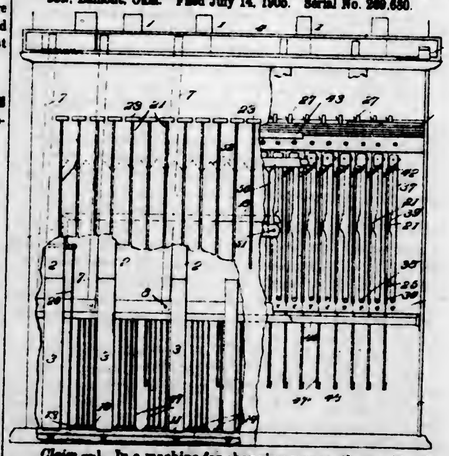


Claim.—1. For the purpose indicated, horizontal shafts sprocket-wheels fixed upon the ends of the said shafts, pontoons upon which the said shafts are rovolably mounted, the sprocket-wheels on the shafts being in correspondence with each other, two pairs of parallel endless chains taking into grooves of the sprocket-wheels, slide-brackets fixed upon the chains, vanes extending across each pair of chains, loops upon the vanes threaded upon the slide-brackets, check-chains connecting the vanes to the sprocket-chains, battens extending across each pair of chains and secured thereto, a loop pivoted upon each batten, a pin upon each vane to engage the said loop, and a lever for operating each loop, substantially as set forth and illustrated.

2. In apparatus for the purpose indicated, sprocket-wheels rovolably mounted in bearings and having grooves around their circumferential peripheries, a pair of endless chains taking into the said grooves, slide-brackets having one end fixed to one link of a chain and the other end fixed to another link, vanes extending across the chains, loops secured to the vanes threaded upon the said slide-brackets, check-chains connecting the vanes to the sprocket-chains, and a spring attached at each end to the check-chains for the purpose of drawing the chains together when the vanes are not in operative position, substantially as set forth.

3. In apparatus for the purpose indicated, a pair of parallel endless chains, battens disposed transversely, and secured at each end to the chains, a loop pivoted in bearings upon the battens, vanes pivoted to the chains, and a pin upon each of the vanes, levers for operating the loops, a pontoon a bearing upon the pontoon, a bolt sliding in the bearing, and a lever for projecting the bolt substantially as set forth.

810,508. MACHINE FOR CHANGING MONEY. DANIEL PETERSON, Lamont, Okla. Filed July 14, 1905. Serial No. 269,680.



Claim.—1. In a machine for changing money, the combination of a series of coin-tubes, coin-delivery mechanism comprising a series of ejectors and a corresponding series of actuators therefor, coin-entrances, selecting and setting mechanisms adapted to be actuated by the coin deposited in a coin-entrance to effect a release of the operating-levers and to throw the required coin-ejector mechanism into operative position, a series of operating-levers operatively connected with the ejecting mechanism to effect delivery of the required amount of change, and a guard to prevent operation of more than one lever at each actuation of the machine.

2. In a machine for changing money, the combination of a series of coin-tubes, means for effecting a delivery of coins from said tubes and comprising a series of ejectors and corresponding actuators, a selecting mechanism for throwing certain of the ejector-actuators out of operation and adapted to be controlled by a deposited coin and a setting mechanism for effecting a release of certain ejector-actuators, and key-operated levers adapted to be released by said setting mechanism.

3. In combination, a series of coin-tubes, cooperating coin-ejectors, actuators therefor, operating means for the actuators, and a selecting mechanism comprising a plurality of members adapted to be independently operated through the instrumentality of a deposited coin, whereby certain actuators are thrown out of operation.

4. In combination, a plurality of coin-tubes, coöperating coin-ejectors, ejector-actuators, operating means for the latter, a selecting mechanism comprising a series of independent operable elements, a series of coin-entrances, and a slide common to all of the coin-entrances and adapted to receive operating elements of said selecting mechanism, whereby any one of the elements of a selecting mechanism may be actuated by a determinate coin deposited in the machine so as to throw certain of the ejector-actuators out of operation.

5. In combination, a series of coin-tubes, coöperating ejectors, actuating means for said ejectors, a setting mechanism adapted to be operated by means of a deposited coin, a series of locking-levers normally preventing operation of the actuating means, and a corresponding series of coöperating levers adapted to be actuated by the said mechanism for throwing the coin-ejector-actuating means into operative position.

6. In combination, a series of coin-tubes, coin-ejectors therefor, actuating means for said ejectors, a series of setting-slides, means for moving a setting-slide through the intervention of a coin deposited in the machine, a series of key-operated levers, means for normally preventing operation of said levers, other levers connected in groups with the respective setting-slides and adapted to effect a release of certain of the key-operated levers, and connecting means between the coin-ejector-actuating means and said levers operated by means of the setting-slides.

7. In combination, a series of coin-tubes, coin-ejectors therefor, actuating means for said ejectors, a series of setting-slides, means for moving a setting-slide through the intervention of a coin deposited in the machine, a series of key-operated levers, means for normally preventing operation of said levers, other levers connected in groups with the respective setting-slides and adapted to effect a release of certain of the key-operated levers, and connecting means between the coin-ejector-actuating means and said levers operated by means of the setting-slides, and means for preventing return of a key-operated lever after being initially moved until it has completed its stroke in the operation of the machine.

8. In combination, coin-delivery mechanism, actuating means therefor, selecting means for throwing certain of the ejector-actuating means out of operation, a setting mechanism to effect a release of certain parts of the ejector-actuating means, for certain of the key-operated levers, and connecting means between the key-operated levers and the ejector-actuating means.

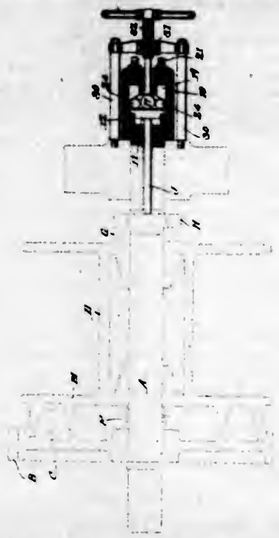
9. In combination, coin-delivery mechanism, actuating means therefor comprising a plurality of elements, a selecting mechanism adapted to throw certain parts of the actuating means out of operation, a series of key-operated levers, locking means therefor, a setting mechanism for throwing the locking means of certain key-operated levers out of action, and means for establishing communication between a certain group of key-operated levers and a corresponding part of the delivery-actuating means.

10. In combination, a series of coin-tubes, coöperating ejectors, a series of ejector-actuators, a selecting mechanism for throwing certain ejector-actuators out of operation, a series of rock-shafts each having operative connection with certain ejector-actuators to effect delivery of a given amount of change, a setting mechanism, a series of key-operated levers, locking means therefor adapted to be actuated by the setting mechanism to effect a release of certain key-operated levers, and connecting means between the key-operated levers and the rock-shafts thrown into operative position by the setting mechanism simultaneously with the release of the key-operated levers corresponding to the value of the coin placed in the machine.

11. In combination, a series of coin-tubes, ejectors, ejector-actuators, a selecting mechanism for throwing certain of the actuators out of operation, a series of rock-shafts having operative connection with certain ejector-actuators, a setting mechanism comprising a series of slides, a series of key-operated levers, locking-levers for the key-operated levers, releasing-levers adapted to effect disengagement of the locking-levers from the key-operated levers and themselves to make engagement therewith and adapted to be operated by the said setting-slides, and connecting means between the said rock-shafts and the releasing-levers for transmitting motion from a key-operated lever to a rock-shaft and the series of ejector-actuators connected therewith.

12. In combination, coin-tubes, coin-ejectors, actuators therefor, selecting mechanism for throwing certain of the actuators out of operation, rock-shafts having certain actuators connected therewith, a selecting mechanism comprising a series of slides, key-operated levers, locking-levers therefor, releasing-levers adapted to be actuated in groups by the said setting-slides, a series of elbow-levers operatively connected with the respective rock-shafts and supporting the respective releasing-levers, and locking means for the key-operated levers to prevent their return after being initially operated until moved to the limit of their stroke.

810,509. **CLUTCH-OPERATING MECHANISM.** CLIFFORD L. REED, Portland, Oreg. Filed May 26, 1905. Serial No. 262,474.



Claim.—1. In a clutch-operating mechanism, a longitudinally-movable member, a thrust-pin, inclined members opposed to the longitudinally-movable members, wedging members movable between the inclined members and the longitudinally-movable member, and means for transmitting movement from the thrust-pin to said wedging members.

2. A longitudinally-movable clutch-operating member, a pair of relatively stationary cams having inclined faces opposed to said member, wedging members movable toward and from each other in the space between the cams and said member, and means for spreading said wedging members.

3. A longitudinally-movable clutch-operating member, in combination with a pair of relatively stationary cams having inclined faces opposed to the member, a pair of rollers movable between said member, and the cams, and means for spreading the rollers.

4. A longitudinally-movable clutch-operating member, in combination with a pair of relatively stationary cams, having inclined faces opposed to said member, a pair of rollers movable between the member and the cams to effect the longitudinal movement of said member, a thrust-pin, and means actuated thereby for spreading said rollers.

5. A longitudinally-movable clutch-operating member, in combination with a plurality of relatively stationary cams, rollers movable between the cams and the operating member to effect longitudinal movement of the latter, a spreading roller movable between and arranged to separate the first rollers, and a thrust member for operating the spreading roller.

6. A longitudinally-movable clutch-operating member, in combination with a plurality of relatively stationary cams having inclined faces opposed to said member, wedging-rollers movable between the cams and said member, a spreading roller arranged to separate the wedging-rollers, and a thrust-pin for operating the spreading roller.

7. A longitudinally-movable clutch-operating member, a plurality of relatively stationary cams having inclined faces opposed to said member, a plurality of wedging-rollers movable between the cams and said member, a spreading roller between the wedging-rollers and of greater diameter than said wedging-rollers, a thrust-pin for engaging the spreading roller, and means for imparting longitudinal movement to the thrust-pin.

8. In a device of the class specified, a revoluble shaft, a casing secured thereto, a clutch-operating pin extending through the shaft, a cross-bar at the end of the pin and arranged within the casing, a pair of cams having inclined faces opposed to the face of the cross-bar, wedging-rollers between the cams and cross-bar, a spreading roller for engaging the wedging-rollers and of greater diameter than said wedging-rollers, a thrust-pin guided in the casing, and a screw for operating said thrust-pin.

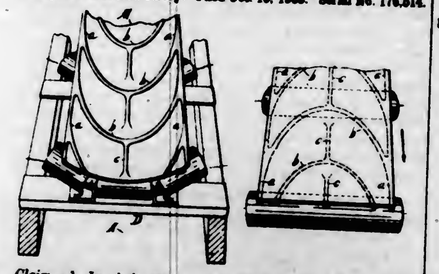
9. In a device of the class specified, the combination with a revoluble shaft, of a casing secured thereto, a clutch-operating pin extending through the shaft, a cross-bar at the end of the pin and disposed within the casing, springs tending to move the cross-bar and pin to unclutching position, a pair of cams arranged in the casing and having inclined faces opposed to the faces of the cross-bar, means for adjusting said cams, a pair of wedging-rollers movable between the cams and bar, a spreading roller arranged to engage the wedging-rollers, a non-circular thrust-pin engaging the spreading roller, and a screw for imparting longitudinal movement to the thrust-pin.

10. In a device of the class specified, the combination with a revoluble shaft, of a casing secured thereto, a clutch-operating pin extending through the shaft, a cross-bar at the end of the pin and disposed within the casing, springs disposed within the casing and engaging the cross-bar, the springs tending to move the cross-bar to clutch-disengaging position, removable filling-plates carried by the casing at points adjacent to the springs to permit renewal of the latter, cams carried by the casing and having inclined faces opposed to the face of the cross-bar, means for adjusting said cams, a pair of wedging-rollers disposed between the cams, and cross-bar, a spreading roller between the wedging-rollers, and of greater diameter than the latter, a non-circular thrust-pin guided by the casing, a pin-actuating screw, a stationary nut for said screw, and an operating means secured to the end of the screw.

11. A movable clutch-operating pin, a cross-bar for transmitting movement thereto, a pair of rollers movable on said bar and serving through the latter to impart endwise movement to the pin, and means for spreading said rollers.

12. A movable clutch-operating pin, a cross-bar for transmitting movement thereto, a pair of rollers engaging the bar, means for spreading the rollers, and means for directing the rollers against the bar during such spreading movement.

810,510. **BELT CONVEYER.** THOMAS ROBINS, Jr., New York, N. Y., assignor to Robins Conveying Belt Company, New York, N. Y., a Corporation of New Jersey. Filed Oct. 10, 1903. Serial No. 176,514.



Claim.—1. In a belt conveyer, the combination with troughing-idlers, end pulleys and driving means, and a snub-pulley, of a conveyer-belt provided on its carrying-surface with a system of spaced ribs or elevations so arranged as to run smoothly over the snub-pulley, and prevent contact of said pulley with any portion of the belt except the ribs or elevations.

2. In a belt conveyer, the combination with troughing-idlers, return-idlers, end pulleys and driving means, and a snub-pulley, of a conveyer-belt provided on its carrying-surface with a system of spaced ribs or elevations so arranged as to run smoothly over the return-idlers and snub-pulley, and to prevent contact of the return-idlers and snub-pulley with any portion of the belt between said ribs or elevations.

3. In a belt conveyer, the combination with a series of troughing-idlers arranged to support a belt traveling upward at an angle to the horizontal, of a conveyer-belt traveling on said idlers and provided on its carrying-surface with spaced ribs or elevations diverging forwardly from the middle of the belt.

4. In a belt conveyer, the combination with a series of troughing-idlers arranged to support a belt traveling upward in an inclined plane, of a conveyer-belt provided on its carrying-surface with a system of spaced ribs or elevations arranged to run smoothly over return-idlers, and comprising longitudinal and transverse elements embodied in ribs or elevations diverging forwardly from the middle of the belt toward the margins thereof.

5. A belt for conveyers and analogous structures, provided on its carrying-surface with a system of ribs or elevations, comprising longitudinal elements arranged to present a substantially continuous structure and transverse elements of the same height as the longitudinal elements and spaced apart.

6. A belt for conveyers and analogous structures, provided upon its carrying-surface with marginal and transverse elevations of the same height.

7. A belt for conveyers and analogous structures, provided on its carrying-surface with longitudinally-disposed elevations at the margins and in the middle of the belt, and spaced transverse elevations.

8. A belt for conveyers and analogous structures having upon its carrying-surface a system of ribs or elevations comprising longitudinal and transverse elements embodied in ribs converging from the margins of the belt to the middle thereof.

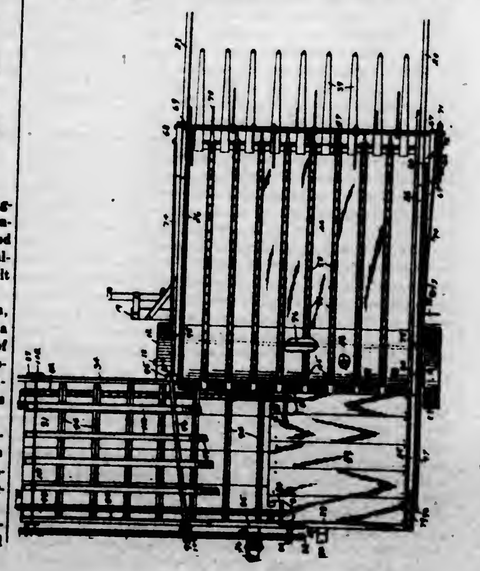
9. A belt for conveyers and analogous structures having on its carrying-surface a system of ribs or elevations comprising longitudinal and transverse elements embodied in ribs, each presenting a single curve substantially tangent at its extremities to the margins of the belt and transverse to the belt at the middle.

10. A belt for conveyers and analogous structures having on its carrying-surface a system of ribs or elevations comprising longitudinal and transverse elements embodied in marginal ribs and in ribs each presenting a single curve tangent at its ends to said marginal ribs and transverse to the belt in the middle.

11. A belt for conveyers and analogous structures having on its carrying-surface a system of ribs or elevations comprising longitudinal and transverse elements, embodied in longitudinal ribs at the margins and in the middle of the belt and in ribs each presenting a single curve tangent at its extremities to the margins of the belt and transverse to the belt in the middle.

12. A belt for conveyers and analogous structures having on its carrying-surface a system of ribs or elevations comprising marginal ribs, curved ribs tangent at their extremities to the marginal ribs and transverse to the belt in the middle, and short longitudinal ribs in the middle of the belt extending from the convexities of said curved ribs.

810,511. **GRAIN-SHOCK AND HAY LOADER.** MICHAEL J. ROONEY and JAMES J. FORD, Fort Dodge, and FRANK M. CONROY, ABRAHAM BURSON, and FRED W. FITCH, Fonda, Iowa. Filed Mar. 31, 1904. Serial No. 199,207.



Claim.—1. In a device of the class described, a series of runners, the outer ends of which are designed to slide over the ground-surface as the machine is advanced, a driven shaft extending across the machine and above said runners, gathering-arms on said shaft, and means for swinging said shaft forwardly and rearwardly to increase or diminish the distance between the gathering-arms and the runners.

2. In a device of the class described, a series of runners, the outer ends of which are designed to slide over the ground-surface as the machine is advanced, a driven shaft extended across the machine and above said runners, gathering-arms on said shaft, and means for swinging said shaft forwardly and rearwardly to increase or diminish the distance between the gathering-arms and the runners, for the purposes stated.

3. In a device of the class described, a series of runners, the outer ends of which are designed to slide over the ground-surface as the machine is advanced, means for adjusting said runners and maintaining them in position, a driven shaft extending across the machine and above said runners, gathering-arms on said shaft, and means for swinging said shaft forwardly and rearwardly to increase or diminish the distance between the gathering-arms and the runners, for the purposes stated.

4. In a device of the class described, a series of runners, gathering-arms rotatably mounted above said runners, curved with concave sides rearward with respect to the direction of rotation and designed when rotated to throw the top of a bundle of straw rearwardly and downwardly relative to the runners, and means for rotating said gathering-arms as the device is advanced over the ground-surface, and means for moving the gathering-arms forwardly or rearwardly, for the purposes stated.

5. In a device of the class described, the combination of a series of runners extending longitudinally of the device, a conveyer mounted partially above said runners and extending longitudinally of the device, gathering-arms mounted above the runners curved with concave sides rearward with respect to the direction of rotation and means for operatively connecting the conveyer with the main driving-shaft, and shields mounted near the rear of said conveyer, designed to raise the material elevated by the conveyer upwardly and out of engagement with it and allow said substance to fall rearwardly, and means for adjusting the gathering-arms toward or away from the runners.

6. In a device of the class described, the combination of a series of runners extending longitudinally of the device, a conveyer mounted partially above said runners and extending longitudinally of the device, gathering-arms mounted above the runners curved with concave sides rearward with respect to the direction of rotation and means for adjusting the gathering-arms forwardly or rearwardly, means for operatively connecting the conveyer with the main driving-shaft, the shields mounted near the rear of said conveyer, designed to raise the material elevated by the conveyer upwardly and out of engagement with it and allow said substance to fall rearwardly, an inclined platform mounted behind and partially beneath said shields, an elevating-conveyer having its lower end mounted beneath the lower end of said inclined platform designed to carry substance which has been dropped onto the inclined platform upwardly and to the side of the machine.

7. In a device of the class described, the combination of a series of runners extending longitudinally of the device, a driven conveyer mounted partially above and extending outwardly from said runners, an inclined platform at the rear of said conveyer, a second conveyer inclined upwardly and substantially at right angles to the first conveyer and mounted behind it, a series of springingly-mounted bars extending above said second conveyer designed to hold the material which is being elevated on it and a driven shaft extending across the machine and above said runners, gathering-arms on said shaft curved with concave sides rearward with respect to the direction of rotation and means for swinging the gathering-arms forwardly or rearwardly and for maintaining them in position, and a draft device on each side of the machine and immediately in front of each of the traction-wheels of the device.

8. In a device of the class described, the combination of a series of runners extending longitudinally of the device, a driven conveyer mounted partially above and extending outwardly from said runners, an inclined platform at the rear of said conveyer, a second conveyer inclined upwardly and substantially at right angles to the first conveyer and mounted behind it, a series of springingly-mounted bars extending above said second conveyer designed to hold the material which is being elevated on it, and a driven shaft extending across the machine, and above said runners, gathering-arms on said shaft curved with concave sides rearward with respect to the direction of rotation and means for swinging the gathering-arms forwardly or rearwardly and for maintaining them in position, and a draft device on each side of the machine and immediately in front of each of the traction-wheels of the device, and a bar on each side of the device to which the draft-animals are hitched.

9. In a device of the class described, traction-wheels having a driving-shaft mounted between said traction-wheels, a frame mounted on said shaft, said frame having rounded forward ends designed to engage and slide over the ground-surface as the machine is advanced, a caster designed to support the rear of said frame, runners mounted at the forward end of said frame, gathering-arms curved with concave sides rearward, with respect to the direction of rotation and mounted above said runners, means for adjusting the gathering-arms forwardly or rearwardly, means for operatively connecting the driving-shaft with the gathering-arms and a conveyer extending longitudinally of said frame and partially above said runners.

10. In a device of the class described, traction-wheels having a driving-shaft mounted between said traction-wheels, a frame mounted on said shaft, said frame having rounded forward ends designed to engage and slide over the ground-surface as the machine is advanced, a caster designed to support the rear of said frame, runners mounted at the forward end of said frame, gathering-arms curved with concave sides rearward with respect to the direction of rotation and mounted above said runners, means for moving the gathering-arms forwardly or rearwardly, means for operatively connecting the driving-shaft with the gathering-arms, and a conveyer extending longitudinally of said frame and partially above said runners, and an inclined platform at the rear of said conveyer, and an elevating-conveyer substantially at right angles to the first-mentioned conveyer having its lower end beneath the lower end of said inclined platform and substantially at right angles to the first-mentioned conveyer.

11. In a device of the class described, a frame mounted on traction-wheels, a series of runners at the front end of said frame, a series of inclined boards above and extending rearwardly from said runners, a series of conveyer-chains mounted between said boards, having prongs projecting outwardly therefrom, said boards and said conveyer-chains designed to form an elevating-conveyer, a driven shaft extending across the frame and above said runners, gathering-arms on said shaft curved with concave sides rearward with respect to the direction of rotation and means for moving the driven shaft forwardly or rearwardly, for the purposes stated.

12. In a device of the class described, a frame mounted on traction-wheels, a series of runners at the front end of said frame, a series of inclined boards above and extending rearwardly from said runners, a series of conveyer-chains mounted between said boards having prongs projecting outwardly therefrom, said boards and said conveyer-chains designed to form an elevating-conveyer, a driven shaft extending across the frame and above said runners, and gathering-arms on said shaft curved with concave sides rearward, with respect to the direction of rotation and means for swinging the driven shaft forwardly or rearwardly, an inclined platform at the rear of said conveyer, a second elevating-conveyer having its lower end beneath the lower end of said inclined platform, and means connected with the main driving-shaft for operating said second conveyer.

810,512. WAGON-BOX AND HAY-RACK LIFTER. MICHAEL J. SAGGAU, St. Mathias, Minn. Filed Sept. 28, 1904. Serial No. 226,504.

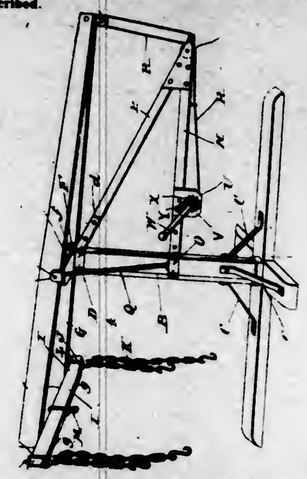
Claim.—1. In a lifting device, an upright post, a lever fulcrumed on the top of said post and revolubly mounted thereon, an arm revolubly mounted on said post, a drum suitably journaled, and a cable connecting said lever and drum, said arm and lever being connected for simultaneous swinging, substantially as shown and described.

2. In a lifting device, an upright post, a cap-piece revolubly mounted on the upper end of said post, an arm revolubly mounted on said post, a brace connecting said cap-piece and the free end of said arm, a lever fulcrumed on said cap-piece, a drum suitably journaled, and a cable connecting said lever and drum, substantially as shown and described.

3. In a wagon-box and hay-rack lifter, lever-arms suitably journaled, a lifting-beam secured to said arms and having its ends extended on each side of same, lifting devices mounted on said extended ends, and means to adjust said lifting devices on said ends, substantially as shown and described.

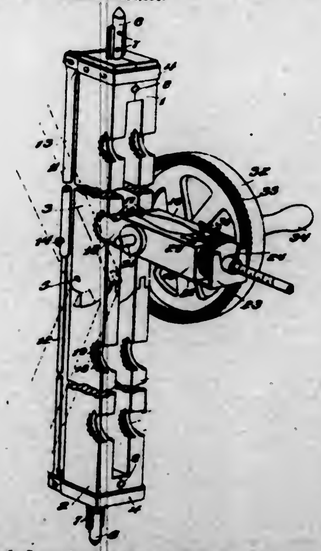
4. In a wagon-box and hay-rack lifter, an upright post, a triangular lever-frame suitably pivoted and revolubly mounted on said post, an arm revolubly mounted on said post and arranged for simultaneous revolution with said lever-frame, and means secured to said arms for swinging said lever-frame, substantially as shown and described.

5. In a wagon-box and hay-rack lifter, an upright post, a beam revolubly mounted on said post, a triangular lever-frame fulcrumed on said beam, an arm revolubly mounted on said post, a brace-bar connecting said arm and beam, a drum journaled on said arm, and a rope connecting said lever-frame and drum, substantially as shown and described.



6. In a wagon-box and hay-rack lifter, an upright post, a beam revolubly mounted on said post, lever-arms fulcrumed on said beam, a lifting-beam secured to the ends of said lever-arms and having its ends extended beyond the ends of said lever-arms, and holes in said extended ends, lifting devices adjustably mounted on said lifting-beam, pins to be inserted in the holes in said beam to hold said lifting devices in their adjusted positions, an arm revolubly mounted on said post, a brace-rod connecting said revoluble beam and arm, a drum journaled on said arm, and a rope connecting said drum and the lever-arms, substantially as shown and described.

810,513. MINER'S DRILL. HENRY TODD, Marshfield, Ohio. Filed Mar. 23, 1905. Serial No. 251,080.



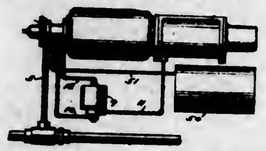
Claim.—1. In a miner's drill, the combination of a supporting-frame or upright composed of pivoted sections adapted for approximately vertical alinement or angular adjustment, points for the sections, and a brace connecting the sections and adjustable to hold the same vertically alined or arranged at an angle to each other.

2. In a miner's drill, the combination of a supporting-frame or upright composed of sections pivotally connected at one end, a brace comprising sections having a sliding connection at one end, each section having a pivotal connection at its opposite end with one section of the upright, and means for holding the sections of the brace at a predetermined adjustment.

3. In a miner's drill, a frame or upright embodying sections pivotally connected to one another, and a brace pivotally connected at one end with the upper extremity of one section of the supporting-frame and at its opposite end with the lower extremity of said frame, said brace consisting of telescoping sections.

4. In a miner's drill, the combination of a supporting-frame or upright provided longitudinally thereof with a plurality of notched portions, the notched portions being formed with a plurality of teeth in the length thereof, and a drilling mechanism including a drill-supporting frame having a member adapted to be seated in a selected notched portion of the upright or frame and formed with an engaging tooth adapted to engage a tooth in the length of such notched portion to hold the drill-supporting frame at a predetermined adjustment.

810,514. FLUID-PRESSURE BRAKE. WALTER V. TURNER, Wilkinsburg, and JOHN S. CURTIN, Pittsburg, Pa., assignors to The Westinghouse Air Brake Company, Pittsburg, Pa., a Corporation of Pennsylvania. Filed Apr. 27, 1904. Serial No. 205,116.



Claim.—1. In a fluid-pressure brake, the combination with a train-pipe, auxiliary reservoir and brake-cylinder, of a regulating-chamber, a valve device for controlling the supply of fluid to said regulating-chamber, and means operated by the pressure in said chamber for supplying fluid directly to the brake-cylinder.

2. In a fluid-pressure brake, the combination with a train-pipe, auxiliary reservoir and brake-cylinder, of a regulating-chamber, a valve device operating in response to variations in train-pipe pressure for controlling the supply of fluid to said regulating-chamber, and means operated by the pressure in said chamber for regulating the brake-cylinder pressure.

3. In a fluid-pressure brake, the combination with a train-pipe, auxiliary reservoir and brake-cylinder, of a regulating-chamber, a valve device operated by a reduction in train-pipe pressure for supplying fluid from the auxiliary reservoir to the brake-cylinder and for controlling the supply to said regulating-chamber, and means operated by the pressure in said chamber for regulating the brake-cylinder pressure.

4. In a fluid-pressure brake, the combination with a train-pipe, auxiliary reservoir and brake-cylinder, of a regulating-chamber, a valve device operated by a reduction in train-pipe pressure for supplying fluid from the auxiliary reservoir to the brake-cylinder and for controlling the supply to said regulating-chamber, and a valve device governed by the pressure of said regulating-chamber for also supplying fluid to the brake-cylinder.

5. In a fluid-pressure brake, the combination with a train-pipe, auxiliary reservoir and brake-cylinder, of a regulating-chamber, a valve device operating in response to variations in train-pipe pressure for supplying fluid from the auxiliary reservoir to the brake-cylinder and from the train-pipe to the regulating-chamber, and means operated by the pressure in said chamber for regulating the brake-cylinder pressure.

6. In a fluid-pressure brake, the combination with a train-pipe, auxiliary reservoir and brake-cylinder, of a regulating-chamber, a valve device operating in response to variations in train-pipe pressure for supplying fluid from the auxiliary reservoir to the brake-cylinder and from the train-pipe to the regulating-chamber, and means operated by the pressure in said chamber for also supplying fluid from the train-pipe to the brake-cylinder.

7. In a fluid-pressure brake, the combination with a train-pipe, auxiliary reservoir and brake-cylinder, of a regulating-chamber of predetermined capacity independent of the brake-cylinder, a valve

device operating in response to variations in train-pipe pressure for controlling the supply of fluid to said regulating-chamber, and means operated by the pressure in said chamber for supplying fluid to the brake-cylinder.

8. In a fluid-pressure brake, the combination with a train-pipe, auxiliary reservoir and brake-cylinder, of a regulating-chamber of predetermined capacity independent of the brake-cylinder, a valve device operating in response to variations in train-pipe pressure for controlling the supply of fluid from the auxiliary reservoir to the brake-cylinder and from the train-pipe to the regulating-chamber, and a valve device governed by the pressure of said chamber for supplying fluid to the brake-cylinder.

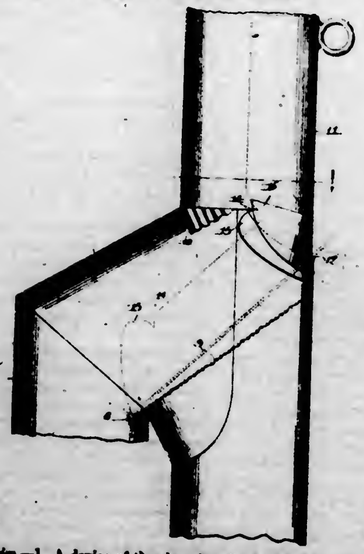
9. In a fluid-pressure brake, the combination with a train-pipe, auxiliary reservoir and brake-cylinder, of a regulating-chamber, and a triple-valve device comprising a piston subject to the opposing pressures of the train-pipe and auxiliary reservoir, a main slide-valve having ports for establishing communication from the train-pipe to the regulating-chamber, and a graduating-valve for controlling the ports in the main slide-valve.

10. In a fluid-pressure brake, the combination with a brake-valve having an equalizing-reservoir and a sliding piston for operating a train-pipe-discharge valve, of means for preserving a tight joint around said piston when the discharge-valve is closed and means governed by the pressure of the equalizing-reservoir for supplying fluid to the train-pipe.

11. In a fluid-pressure brake, the combination with a brake-valve having an equalizing-reservoir and a sliding piston for operating a train-pipe-discharge valve, a seat adapted to be engaged by said piston when the discharge-valve is closed, and means operated by the opposing pressures of the equalizing-reservoir and train-pipe for controlling the supply of fluid to the train-pipe.

12. In a fluid-pressure brake, the combination with a brake-valve having an equalizing-reservoir, a sliding piston operated by the opposing pressures of the equalizing-reservoir and train-pipe, a slide-valve operated by said piston for controlling a train-pipe-discharge port, a seat adapted to be engaged by said piston, and means governed by the pressure in the equalizing-reservoir for supplying fluid to the train-pipe.

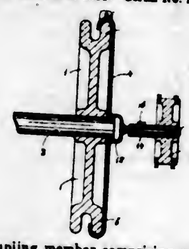
810,515. COMBINED STRAINER AND CUT-OFF. ARNOLD W. WEBER, Bellevue, Iowa, assignor of one-half to Anthony Brandt, Bellevue, Iowa. Filed June 27, 1905. Serial No. 267,277.



Claim.—1. A device of the class described comprising a pipe-section for attachment to a down-spout and having its side walls slotted, a waste-pipe communicating with said pipe-section, a screen extending across the pipe-section, a guide-plate carried by said section and disposed above the screen, and a tiltable cut-off valve having one end thereof extending through the slot in the pipe-section and provided with laterally-projecting ears adapted to engage said guide-plate, said valve being movable in the direction of its length to direct the flow of liquid into the waste-pipe.

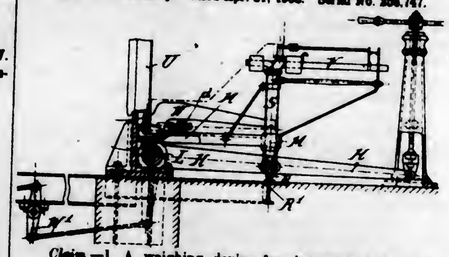
2. A device of the class described comprising a pipe-section for attachment to a down-spout, a waste-pipe communicating with said pipe-section, and a tiltable valve movable transversely of the pipe-section for regulating the flow of liquid into the waste-pipe.

810,516. FRICTION-CLUTCH. JOSEPH F. WILSON, Invercargill, New Zealand. Filed Jan. 9, 1905. Serial No. 240,374.



Claim.—A coupling member comprising a disk made in two parts the outer edge of which disk is bent to overlap and be secured to the periphery of another object supported on the axle, one of said parts being formed with a hollow boss fitting over the end of the axle and with a spindle extending outwardly from the boss to support the sleeve of another member, the two parts of the disk being united at one point by a hinge-joint, and at the opposite point by a bolt passing through ears formed on the periphery of the disk on each side of the line of separation, substantially as described.

810,517. WEIGHING DEVICE FOR VEHICLES. EMIL T. ZEIDLER, Riga, Germany. Filed Apr. 21, 1905. Serial No. 256,747.



Claim.—1. A weighing device for determining the single-wheel pressures of railway-vehicles comprising in combination the balance proper, a weighing-lever for transferring the wheel-load to the balance, an edge body secured to said lever, a frame M for carrying the said lever, a shaft parallelly arranged to the rails and supporting said frame, and means for rotating the shaft, substantially as described and for the purpose set forth.

2. A weighing device for simultaneously determining the pressure of a plurality of railway-vehicle wheels, comprising in combination a corresponding number of balances proper, weighing-levers W for transferring the wheel-loads to the balances, edge bodies secured to said levers, frames carrying said levers, shafts supporting said frames and means for rotating the shafts, substantially as described and for the purpose set forth.

3. A weighing device for determining the single-wheel pressures of railway-vehicles comprising in combination the balance proper, a weighing-lever for transferring the wheel-load to the balance, an edge body secured to said lever, containing the load and the turning edges, a regulating device for adjusting the edge body respectively the weighing-lever, a frame upon which said regulating device is mounted, a shaft parallelly arranged to the rails and supporting said frame, and means for rotating the shaft, substantially as described and for the purpose set forth.

4. A regulating device for adjusting the edge body in respect to the weighing-lever, consisting of a fork-shaped part *k* having two wedge-shaped peaks, movable stop-bearings for carrying the turning edges of the edge body, guides *l* for leading said stop-bearings, and an adjusting-screw mounted in a projection *m* of the frame M, substantially as described and for the purpose set forth.

810,518. ANIMAL-TRAP. FRED BALLENTINE, Moscow, Okla. Filed Sept. 5, 1905. Serial No. 277,689.

Claim.—1. A trap embodying a compartment, a door leading to the compartment, spring means normally tending to hold the door closed, a trigger-bar coacting with the door to hold the same open, a releasing-platform movably mounted in the compartment, and connecting means between said platform and the trigger-bar whereby the trigger-bar may be actuated to permit closing of the door when the platform is moved.

2. A trap comprising a plurality of compartments, a door for each compartment, spring means normally tending to close the door, a trigger-bar for holding the door open, a platform pivotally mounted in each compartment, and a connection between said platform and the trigger-bar, whereby said trigger-bar may be actuated to permit closing of the door.

3. A trap comprising a plurality of compartments, a door for each compartment, an extension projecting from each door at the upper portion thereof, a trigger-bar movably attached to a side of each compartment and adapted to engage the extension of the door adjacent to hold the same open, a spring-arm coacting with the door to close the same, a platform in each compartment pivotally mounted at one end, and a connection between the opposite end of the platform and the trigger-bar whereby movement of the platform will disengage the trigger-bar from the extension of the door to permit closing of the latter.

810,519. WIRE MATTRESS. WALTER BILLS, South Melbourne, Victoria, Australia. Filed July 17, 1905. Serial No. 270,011.

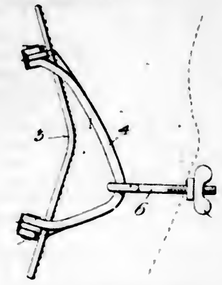
Claim.—1. A wire mattress having a number of comparatively stout wires threaded longitudinally through the fabric one end of each wire being bent back and driven into the side of the bottom bar of the frame while the other end is formed into a hook and attached to a spiral spring, said spring extending through a hole in the top bar of the rigid frame and formed with a bent end adapted to be driven into the side of said bar substantially as set forth.

2. In a wire mattress, the combination of a frame comprising two side bars, a cross-bar rigidly mounted on each end of said side bars, a plurality of wires connected to the end bars, a cross-bar mounted intermediate of the end bars, a woven fabric connected to one end bar and to the intermediate bar, and means to adjust the fabric without adjusting the wires.

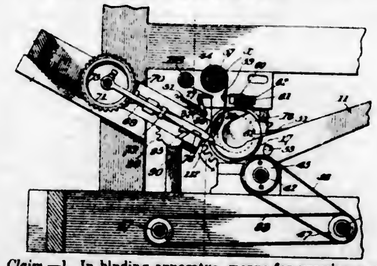
810,520. ANTIKICKING ATTACHMENT. FRANK J. BRADY, Chesnut, Pa. Filed Aug. 14, 1905. Serial No. 274,082.

Claim.—1. An antikicking attachment for cows comprising a plate adapted to rest against the front of the leg, side members pivotally connected to said plate, a cross member adapted to bear against the rear of the leg, adjustable connections between said side members and the cross member, one of said connections being detachable, substantially as described.

2. An antikicking attachment for cows comprising a bent plate, curved rods having inwardly-bent ends pivotally connected to lugs on the front of said plate, a bolt having an eye engaging one of said rods, a bolt having a hook engaging the other, a plate having holes through which both said bolts pass, and nuts on said bolts for clamping the plate, substantially as described.



810,521. BALE-TYING MACHINE. CARTER M. CAGLE, Beckville, Tex. Filed Feb. 23, 1905. Serial No. 246,904.



Claim.—1. In binding apparatus, means for pressing one end of a binding-wire against the article to be bound, means for turning the article to wind the wire therearound, and means for intertwisting the ends of the wire.

2. In binding apparatus, means for simultaneously turning the article and carrying a binding-wire therearound, so that the wire encircles the article, and means for intertwisting the ends of the wire.

3. In binding apparatus, a revoluble support for the reception of the article to be bound, means movable with the support for engaging one end of a wire, means for simultaneously turning the support carrying the wire-engaging means, thereby to wind the wire around the article, and means for intertwisting the ends of the wire.

4. In binding apparatus, a revoluble support for the article to be bound, a wire-clamp carried by the support, and means for clipping the wire after being wound about the article, and for twisting the meeting ends of said wire.

5. In wrapping and binding apparatus, means for simultaneously winding a wrapper and a binding-wire around the article to be bound, and means for twisting the ends of the wire.

6. In binding and wrapping apparatus, means for turning the article to be bound, means for engaging a wrapper and means for engaging the tie-wire and carrying the same around with the article, and means for intertwisting the ends of the tie-wire.

7. In wrapping and binding apparatus, an article-supporting means, means for clamping the end of a wrapper and the end of a tie-wire against the article, means for revolving the support to effect the winding of the wrapper and tie-wire around the article, and means for uniting the ends of the tie-wire.

8. In apparatus of the class described, an article-support, means for clamping one end of a wrapper-strip against the article, means for revolving the article to inclose the article in the wrapper, and means for severing the wrapper-strip into wrapper lengths.

9. In apparatus of the class described, an article-support, means for clamping one end of a wrapper-strip against the article, means for turning the support to envelop the article in the strip, and means for severing the strip into wrapper length in advance of the completion of the enveloping operation.

10. In apparatus of the class described, a revoluble article-support, means for clamping one end of a wrapper-strip against the article and for holding the end of the tie-wire against the wrapper-strip, means for turning the support to encircle the article by the wrapper and tie-wire, means for severing the wrapper-strip into a wrapper-length in advance of the completion of the turning movement, means for subsequently severing the tie-wire, and means for intertwisting the ends of the tie-wire.

11. In apparatus of the class described, a pair of revoluble heads recessed for the reception of the ends of a cotton-bale core, a clamp-bar carried by the heads, a wire-clamp supported by the bar, springs tending to force the clamp-bar inward to engage the periphery of the bale, means for feeding the end of the wrapper-strip against the inner face of the clamp-bar, means for introducing the end of a wire to the wire-clamp, means for turning the heads to effect the encircling of the bale by the wrapper-strip and tie-wire, means for severing the wrapper-strip into a wrapper length in advance of the completion of the turning movement, means for subsequently severing the wire into a binding length, and means for intertwisting the ends of said wire.

12. The combination with a pair of revoluble heads having recesses for the reception of the ends of a bale-core, of a clamp-bar extending between the heads, a wire-clamp carried by the bar, means for introducing the end of a wire into the clamp, means for feeding the end of a wrapper-strip in front of the bar, springs tending to force the bar into contact with the periphery of the bale, normally-locked actuating means for the carrier, means operable by the bale for unlocking the operating means, means for cutting the wrapper-strip and means for cutting the wire, and means for intertwisting the ends of the wire.

13. In apparatus of the class described, a wire-clamping member, means for introducing the end of the wire thereinto, means for turning the article and the clamping member, twisting and severing jaws through which the wire runs during the wrapping operation, said clamp serving to direct the end of the wire between said jaws after the wrapping operation, means carried by the jaws for severing the wire into lengths, and means for turning said jaws to twist the ends of the wire.

14. In apparatus of the class described a needle formed of a pair of spring-arms, one of which is provided with an eye for the passage of the wire, the second arm being arranged to engage with the wire at a point beyond the eye and to hold the wire projected from the needle.

15. In apparatus of the class described, a needle comprising a pair of arms, one of which is yieldable with respect to the other, one of said arms having an eye for the passage of the wire, and the other being arranged to engage and clamp the wire at a point beyond the eye.

16. In apparatus of the class described, a pair of clamping-jaws having wire-severing means, a movable frame carrying the jaws, means normally maintaining the jaws in open position for the reception of the wire, a revoluble wire-carrier arranged to pass the wire around the article to be bound, to hold the wire in front of the jaws, means for advancing the frame and jaws, and gears movable into mesh on forward movement of said frame and adapted to revolve said clamping-jaws and twist the wire.

17. The combination with a pair of revoluble heads having recesses for the reception of a cotton-bale core, of a driving-shaft normally uncoupled from the heads, means for placing the wire around the bale, and means operable on the passage of the bale into said recessed heads for clutching the head to the shaft.

18. The combination with a pair of heads recessed for the reception of a cotton-bale core, of a driving-shaft normally uncoupled from the heads, means for passing a tie around the bale as it is revolved by the heads, means for uniting the ends of the tie, a runway for introducing a bale into the heads, and means operable by the passage of the bale along the runway for connecting the shaft to the heads.

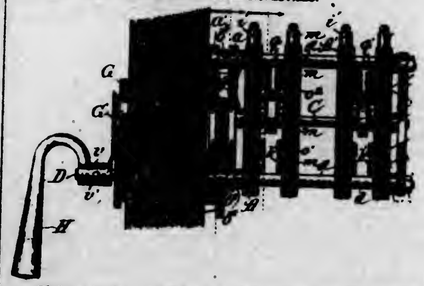
19. The combination with a pair of heads recessed for the reception of the ends of a cotton-bale-core, of a driving mechanism normally disconnected from the heads, means for automatically connecting the heads to the driving means on the bale-core entering said heads, means for passing a tie around the bale as it is revolved with the heads, means for automatically stopping the heads at the completion of each revolution, means for uniting the ends of the tie-wire at the completion of the first revolution of the head, and means for automatically starting a second revolution of the heads after the completion of the tie-forming operation.

20. In a bale wrapping and tying mechanism, a pair of revoluble heads recessed for the reception of the ends of a bale-core, automatic means for enveloping the bale in the wrapper and for passing a tie-wire around the wrapper and bale, said bale being held within the recess during a portion of the travel of the heads by means of the wrapper and wrapper-holding devices, means for severing the wrapper-strip, in advance of the completion of the enveloping operation, and means for effecting the automatic discharge of the completed article from the machine.

21. In a machine of the class described, the combination with a pair of revoluble heads recessed for the reception of the ends of a bale-core, of a driving-shaft, a pair of clutching members mounted thereon, a clutch-operating lever, a runway, means on the runway disposed in the path of the entering bale, and connected to the clutch-operating arm, and means for automatically disconnecting the clutch at the completion of each revolution of the heads.

22. In bale-tying mechanism, a pair of twisting-jaws, gearing connections therefor, a slidable frame carrying the jaws, a cam for engaging and moving the frame to inoperative position, and means for advancing the frame to operative position.

810,522. VOLTMETER-SWITCH. GEORGE H. EASTMAN, Chicago, Ill., assignor to Mineralloe Company, Chicago, Ill., a Corporation of Illinois. Filed Apr. 26, 1905. Serial No. 257,883.



Claim.—1. In a multiple voltmeter-switch, the combination of blocks provided on corresponding faces with series of contacts, with a binding-post, for connection with a voltmeter, on each said block connected with the contacts thereon, blocks alternating with and spaced apart from said first-named blocks and provided on corresponding faces with series of circuit-terminal contacts connected with binding-posts, and a rotary shaft carrying brushes in the spaces between successive blocks, for the purpose set forth.

2. In a multiple voltmeter-switch, the combination of blocks provided on corresponding faces with series of contacts, with a binding-post, for connection with a voltmeter, on each said block connected with the contacts thereon, blocks alternating with and spaced apart from said first-named blocks and provided on corresponding faces with series of circuit-terminal contacts connected with binding-posts, a rotary shaft carrying brushes in the spaces between successive blocks, a dial having an index-finger, and means for turning said finger and shaft, for the purpose set forth.

3. In a multiple voltmeter-switch having circular series of circuit-terminal and voltmeter-terminal contacts, respectively, on the opposing faces of blocks, the combination with said blocks of a rotary brush-carrying shaft to engage the contacts between said opposing faces, an operating-shaft and means for speeding the movement of the brush-shaft relative to that of the operating-shaft by turning the latter, comprising a gear connection between said shaft producing a greater extent of movement of the brushes by a relatively lesser extent of turning the operating-shaft, for the purpose set forth.

4. In a multiple voltmeter-switch having circular series of circuit-terminal and voltmeter-terminal contacts respectively on the opposing faces of successive blocks, the combination with said blocks of a rotary shaft carrying brushes to engage the contacts between said opposing faces, a dial, an operating-shaft, an index-finger actuated by the operating-shaft, and means for speeding the movement of the brush-shaft relative to that of the operating-shaft by turning the latter, comprising a gear connection between said shafts producing a greater extent of movement of the brushes by a relatively lesser extent of turning the operating-shaft, for the purpose set forth.

5. In a multiple voltmeter-switch, the combination of series of circuit-terminal and voltmeter-terminal contacts, a movable brush device for connecting opposite said contacts, and means for connecting at will a dead-circuit-terminal contact with a live one, for the purpose set forth.

6. In a multiple voltmeter-switch, the combination of blocks provided on corresponding faces with series of contacts, with a binding-post, for connection with a voltmeter, on each said block connected with the contacts thereon, blocks alternating with and spaced apart from said first-named blocks and provided on corresponding faces with series of circuit-terminal contacts connected with binding-posts and with means for connecting different said contacts on their respective supporting-blocks, and a rotary shaft carrying brushes in the spaces between successive blocks, for the purpose set forth.

7. In a multiple voltmeter-switch, the combination of blocks provided on corresponding faces with series of contacts, with a binding-post, for connection with a voltmeter, on each said block connected with the contacts thereon, blocks alternating with and spaced apart from said first-named blocks and provided on corresponding faces with series of circuit-terminal contacts connected with binding-posts and with metal rings through the medium of which to connect together contacts on each face, and a rotary shaft carrying brushes in the spaces between successive blocks, for the purpose set forth.

8. A multiple voltmeter-switch, comprising, in combination with a frame, blocks provided on corresponding faces with circular series of contacts, with a binding-post, for connection with a voltmeter, on each said block connected with the contacts thereon, blocks alternating with and spaced apart from said first-named blocks and provided on corresponding faces with series of circuit-terminal contacts connected with binding-posts, plates between which said blocks are confined, a rotary shaft carrying brushes in the spaces between successive blocks and a pinion, a rotary operating-shaft carrying a gear-wheel meshing with said pinion and passing through an opening in the panel, a threaded sleeve extending from a forward plate about the operating-shaft through said panel-opening, a headed sleeve engaging said threaded sleeve at the front side of the panel to clamp the switch thereon, a dial at the front side of said panel, and an index-finger provided with a handle and supported on said operating-shaft, for the purpose set forth.

810,523. NUT-LOCK. HARRISON H. EDGERLE, Cherryvale, Kans. Filed June 5, 1905. Serial No. 263,857.

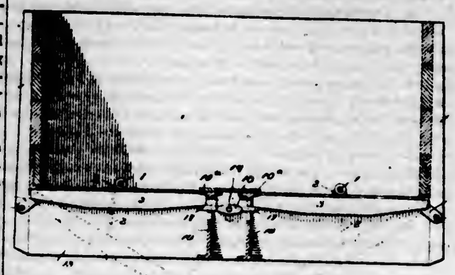
Claim.—In a nut-lock, the combination of a bolt having a recess therein, a nut having a threaded opening which coöperates with the bolt and also having a recess in a side thereof, said recess having communication with the threaded opening and having a keyhole leading therein from the top of the nut, an elbow-shaped locking member pivoted at one end within the recess, the free end thereof being adapted to engage the recess in the bolt to prevent the nut from working loose, a spring comprising two arms arranged at an angle to each other, one arm resting against a side of the recess and fitting within a slot at one end thereof, while the other arm bears against the locking member to hold same normally in engagement with the recess in the bolt, a plate to fit over the opening formed in the side of the nut by the recess, and a removable key for withdrawing the locking member.

810,524. DUMPING-CAR. RICHARD W. ERICSON and JOHN V. ERICSON, Chicago, Ill. Filed July 31, 1905. Serial No. 272,602.

Claim.—1. A dumping-car having doors in the bottom, a winding-shaft and means to turn the same, a cable connecting the shaft and the middle of the doors, to permit them to swing either way, and releasable means to support the doors at opposite edges thereof.

2. A dumping-car having doors in the bottom, hoisting devices having flexible connections to about the middle of the doors, constructed to raise and lower the same and to allow them to swing either way, and means to release either of the opposite edges of the door.

3. A dumping-car having a row of doors in the bottom on each side of the middle, a winding-shaft extending across each row, chains connecting the shaft and the middle of the doors, and means to release either the outer or the inner edge of the doors, to effect either center or side dump.



4. A dumping-car having a row of doors in the bottom on each side of a middle sill, a winding-shaft extending lengthwise across each row of doors and having connections with the doors at about the middle thereof, so that they will swing either way, and means to hold either edge of the doors and to release the opposite edge.

5. The combination with a row of swinging doors in the bottom of a dumping-car, of a rock-shaft extending along the side of the car and having projecting rigidly therefrom a series of supporting-arms having notched ends engageable under the doors when closed, and disengageable therefrom to allow the doors to open.

6. The combination in a dumping-car, of a row of swinging doors in the bottom on each side of the middle, devices supported on the frame of the car under the middle of the floor thereof and between said doors and constructed to engage the adjacent edges of said doors and hold them closed, and means to simultaneously release said devices on both sides, to allow the doors to open.

7. The combination in a dumping-car, of a middle sill, a row of swinging doors in the bottom of the car on each side of the sill, latch devices carried on the sill and engageable with the inner edges of the doors to hold them closed, and a shaft extending along the sill between said devices and having cam-arms bearing against said devices to hold the same engaged, said shaft being provided with means to turn the same to release said devices.

8. A dumping-car having doors in the bottom which swing down to open, said doors having each a middle support, and releasable supports at both edges, either of which may be released, to dump toward the middle or the sides of the car.

9. A car having an end floor-section which may be raised or lowered to form either a hopper or flat bottom, and a cross-piece which extends between the sides of the car and which may be shifted under the floor-section to support the same in raised position.

10. A car having an end floor-section which may be raised or lowered to form either a hopper or flat bottom, a cross-piece extending between the sides of the car at the upper edge thereof and shiftable along the same to support the floor-section, and a board hinged to the cross-piece and arranged to hang down beside the end of the car when the cross-piece is shifted to said end, and to extend across the sides of the car when the cross-piece is shifted under the floor-section.

810,525. COMBINED CAR AXLE AND WHEEL STRUCTURE. LEWIS P. FERRIS, Chicago, Ill. Filed Apr. 3, 1905. Serial No. 253,603.

Claim.—1. A combined car wheel and axle, the axle of which has a cored-out portion filled with a non-liquid metal differing in rate and amplitude of vibration from the body of the axle, substantially as described.

2. A combined car wheel and axle, the axle of which has a cored-out portion filled with a hard metal differing in rate and amplitude of vibration from the body of the axle, substantially as described.

3. A combined car wheel and axle, the axle of which has a cored-out portion extending from end to end and containing a hard metal, the rate and amplitude of vibration of which differs from that of the body of the axle, substantially as described.

4. A car-axle having a cored-out portion filled with a non-liquid metal differing in rate and amplitude of vibration from the body of the axle and wheels mounted thereon composed of metals also differing in rate and amplitude of vibration, substantially as described.

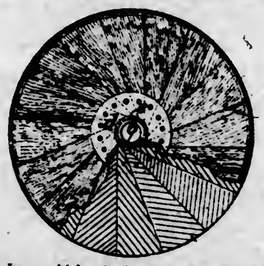
5. A car-axle having a cored-out portion filled with a hard metal differing in rate and amplitude of vibration from the body of the axle and wheels mounted thereon composed of metals also differing in rate and amplitude of vibration, substantially as described.

6. A car wheel and axle structure comprising in combination a car-axle cored out from end to end and filled with a hard metal differing in rate and amplitude of vibration from the body of the axle and wheels mounted thereon composed of a plurality of plates, the rate and amplitude of vibration of some or all of which differs, substantially as described.

7. A combined car axle and wheel structure, comprising in combination an axle, the core of which is composed of copper and differs in rate and amplitude of vibrations from the material of which the body of said axle is composed, a wheel secured upon said axle and composed of a plurality of plates, one of which is also of copper, and differs in rate and amplitude of vibrations from the other plates, and means electrically connecting said copper plate with the core of the axle, substantially as described.

8. A combined car axle and wheel structure, the axle of which comprises in combination a cored-out portion filled with a material, the rate and amplitude of the vibrations of which differ from the body of the material, said axle being surrounded with a third material, the rate and amplitude of vibrations of which differ from said body portion, substantially as described.

810,526. WHEEL FOR VEHICLES. THOMAS GARE, New Brighton, England. Filed Jan. 15, 1904. Serial No. 189,173.



Claim.—1. In a vehicle-wheel, segmental sections with their sides fitting against each other tangent to the bore of the wheel, substantially as and for the purpose set forth.

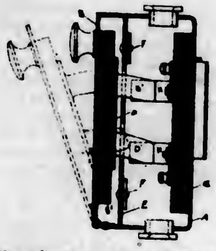
2. In a vehicle-wheel, segmental sections fitted together tangentially to the bore of the wheel and vulcanized rubber inserted between the said sections, all combined substantially as and for the purpose set forth.

3. In a vehicle-wheel, segmental sections with their sides fitting against each other tangent to the bore of the wheel, a boss in the latter having flanges and rivets through the said flanges and segmental sections securing the same together, all combined substantially as and for the purpose set forth.

4. In a vehicle-wheel, segmental sections fitted together around the bore of the wheel and shaped to provide a zigzag circumference forming recesses, wedge-like pieces fitted into the latter and vulcanized rubber inserted between the said zigzag or undulated circumference and the said wedge-shaped pieces, all substantially as and for the purpose set forth.

5. In a vehicle-wheel, segmental sections fitted together around the bore of the wheel and shaped to provide a zigzag circumference forming recesses, wedge-like pieces fitted into the latter, rubber inserted between the said sections and wedge-like pieces, a boss in the bore of the wheel having flanges, rings at each side of the wheel and rivets passing through the said segmental sections and wedge-shaped pieces, flanges and rings respectively, all substantially as and for the purpose set forth.

810,527. ELECTRICAL SWITCH. JOSEPH P. GOSSER, New York, N. Y., assignor, by mesne assignments, to Empire Electric Stage Lighting Company, a Corporation of New York. Filed Oct. 7, 1904. Serial No. 227,889.

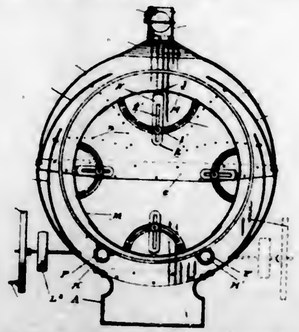


Claim.—1. In an electric switch, a pair of separated contacts inclosed in a protecting-case, and a partition having narrow openings, in combination with a hinged cover carrying movable contacts arranged to be thrust through such openings adapted for joint operation substantially as herein specified.

2. The double knife-switch described having two pairs of separated contacts inclosed in a protecting-case, and a partition having narrow openings, in combination with a cover carrying movable contacts arranged to be thrust through such openings adapted for joint operation, substantially as herein specified.

3. In an electric switch, a pair of separated contacts inclosed in a protecting-case, and a partition having narrow openings, in combination with a cover carrying movable contacts arranged to be thrust through such openings and with removable fastenings F allowing the easy removal of such partition at will, all adapted for joint operation substantially as herein specified.

810,528. APPARATUS FOR HEATING TIRES. GEORGE W. GRAVES, Detroit, Mich., assignor to Daniel D. Frisbee, Detroit, Mich. Filed Dec. 19, 1904. Serial No. 237,474.



Claim.—1. In an apparatus of the character described, the combination with a casing formed by two detachable semicylindrical sections and having a combustion-chamber at its lower end, of tire-supports above and on opposite sides of said combustion-chamber, and means for imparting rotary motion to the tire upon said supports.

2. In an apparatus of the character described, the combination with a casing formed by two detachable semicylindrical sections and having a combustion-chamber at its lower end, of a pair of roller-supports arranged respectively upon opposite sides of said combustion-chamber and upon which the lower segment of the tire is adapted to rest, and means for imparting rotary motion to said rolls to revolve the tire.

3. In an apparatus of the character described, the combination with a circular casing having a combustion-chamber below the same and connected therewith, of roller-supports for the tire arranged upon opposite sides of said combustion-chamber and an expansible and contractible annular shield above said supports.

4. In an apparatus of the character described, the combination with a circular casing having a combustion-chamber below the same and connected thereto, of roller-supporting bearings on opposite sides of said combustion-chamber, rollers on said bearings, an annular expansible and contractible shield above said supports, and a series of segmental shields within said casing hinged at their lower ends thereto and having their upper ends adjustable toward or from the casing.

5. In an apparatus of the character described, the combination with a casing and supports therein, of a shield comprising a pair of segmental plates, a radially-adjustable bracket to which said plates are hinged, segments on said plates, and a common clamping-screw for securing said bracket and segments to hold said plates in different positions of adjustment.

6. In an apparatus of the character described, the combination with a casing having a combustion-chamber at its lower end, of roller-supports for the tire on opposite sides of said combustion-chamber and rotatably-adjustable shields for protecting said roller-supports.

7. In an apparatus of the character described, the combination with a substantially circular casing having a combustion-chamber therein, and an annular shield comprising overlapping segmental sections adjustable relatively to one another.

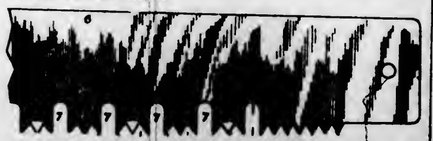
8. In an apparatus of the character described, the combination with a casing and supports therein, of an annular shield comprising segmental plates arranged in pairs, the contiguous edges of adjacent pairs overlapping, radially-adjustable brackets to which each pair of the plates is hinged, segments on said plates and means for securing said brackets and segments to hold said plates in different positions of adjustment.

9. In an apparatus of the character described, the combination with a casing having a combustion-chamber at its lower end, of roller-supports for the tire on opposite sides of said combustion-chamber, and shields separating said roller-supports from the combustion-chamber.

810,529. COMPRESSIBLE PACKING FOR WOOD-BLOCK ROAD-PAVING. CHARLES W. GREGORY, Jr., Bristol, England. Filed Mar. 21, 1905. Serial No. 251,353.

Claim.—In combination, a casing, a series of corrugated layers within the casing, the upper layer being of greater length than the remaining layers and being bent at its ends to inclose the remaining layers and lap the lower layer, strips interposed between the casing and the corrugated layers and between the corrugated layers, the upper strip being of greater length than the remaining strip and having its ends lap the lower strip and a textile cover for the casing, the cover, casing, layers and strips being treated with tar.

810,530. SAW. JOHN GUEBEL, Indianapolis, Ind. Filed July 15, 1905. Serial No. 269,573.



Claim.—1. In a saw, combined rake and cutting teeth which are not swaged having one straight edge approximately at right angles to the longitudinal dimensions of the saw-blade, and a second side inclined to the first, said combined rake and cutting teeth being grouped in pairs with their inclined sides toward each other, the inclined edges of said teeth of each pair being sharpened on the same side of the saw-blade but said teeth of adjacent pairs being sharpened on opposite sides of the blade, and triangular cutting-teeth swaged in alternate opposite directions, introduced singly between each pair of said combined rake and cutting teeth.

2. A saw having teeth in groups separated by deep gullets, said groups, except at the extreme end of the saw-blade, consisting of three teeth, the outer teeth of said groups having straight square outer edges approximately at right angles to the longitudinal dimensions of the blade, and inner inclined edges the latter edges of both teeth sharpened on one and the same side of the blade to form cutting edges at the opposite side of the blade, the said teeth of adjacent groups being filed from opposite sides of the blade to produce a double row of cutting-points at the ends of the teeth separated by the thickness of the blade, and a middle triangular cutting-tooth in each group sharpened on opposite sides of the blade from that of the other two teeth of the group, said cutting-teeth being swaged toward the cutting edges of said teeth.

3. In a saw, a pair of combined rake and cutting teeth, each having one straight square edge approximately at right angles to the longitudinal dimensions of the saw-blade and having a second edge inclined to the first edge, said inclined edges of the two teeth of a group being sharpened on the same side of the blade to form cutting edges on the opposite side of the blade, said teeth of adjacent groups being sharpened from opposite sides of the blade, said teeth not being swaged and together forming two cutting rows separated at the ends of the teeth, by the thickness of the saw-blade, and a single triangular swaged cutting-tooth between each pair of the first-described teeth forming a group of three teeth, the last-named teeth of each group being swaged in alternate opposite directions to form cutting-points in two additional lines.

810,531. PROCESS OF HARDENING STEEL. ROBERT A. HADFIELD, Sheffield, England. Filed Feb. 18, 1903. Serial No. 143,997.

Claim.—1. The method of hardening steel which consists in raising the temperature of the steel to about 975° centigrade; permitting it to cool slowly; reheating the cooled steel to a temperature of about 500° centigrade; and permitting the steel to cool slowly after such reheating.

2. The method of hardening steel and imparting thereto high resistance to compression, which consists in raising the temperature of the steel to above 850° centigrade and not over 1,150° centigrade; permitting it to cool slowly; reheating the cooled steel to a temperature of or over 680° centigrade, and permitting the steel to cool slowly immediately after such reheating.

3. The method of hardening steel and imparting thereto high resistance to compression, which consists in raising the temperature of the steel to between 975° centigrade and 1,000° centigrade; permitting the steel to cool slowly; reheating the cooled steel to a temperature of or over 500° centigrade, and slowly cooling the steel after such reheating.

4. The method of hardening steel, which consists in raising the temperature of the steel to above 850° centigrade and not over 1,150° centigrade; permitting it to cool slowly to about the temperature of the external air; reheating the cooled steel to a temperature not higher than 720° centigrade, and finally slowly cooling the steel after reheating.

5. The method of hardening steel, which consists in raising the temperature of the steel to not less than 850° centigrade and not more than 1,150° centigrade; permitting the steel to cool; reheating the cooled steel to a temperature not higher than 720° centigrade, and immediately thereafter permitting the steel to cool slowly from the reheating temperature.

6. The method of hardening steel which consists in raising the temperature of the steel above 975° centigrade, and below 1,150° centigrade, permitting it to cool slowly; reheating the cooled steel to a temperature of or over 500° centigrade, and finally slowly cooling the steel after such reheating.

7. The method of hardening steel and imparting thereto high resistance to compression, which consists in raising the temperature of the steel to about 975° centigrade, permitting the steel to cool slowly, reheating the cooled steel to a temperature of or over 680° centigrade and below 720° centigrade, and slowly cooling the steel from such last-named temperature.

8. The method of hardening steel, which consists in raising the temperature of the steel from about 850° centigrade upward, and not higher than 1,150° centigrade; cooling the steel to not more than 400° centigrade; reheating the partially-cooled steel to about 500° centigrade and upward, and finally permitting the reheated steel to cool.

9. The method of hardening steel which consists in raising the temperature of the steel to from about 850° centigrade upward to but not higher than 1,150° centigrade, according to the amount of carbon in the steel; cooling the steel slowly to not more than 400° centigrade, reheating the cooled steel to a temperature of about 500° centigrade and upward according to the hardness or toughness required; and immediately and slowly cooling the reheated steel from the reheating temperature.

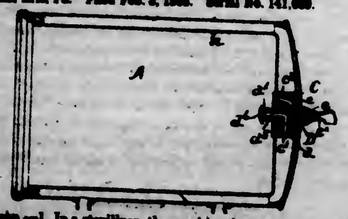
810,532. COMBINED OIL PUMP AND MEASURE. WILLIAM B. HARRIS, Sunbury, Pa. Filed Oct. 10, 1903. Serial No. 177,077.

Claim.—1. In an apparatus for the purpose described, the combination of a measuring-pump having its cylinder or barrel extended upwardly to form a measuring-chamber, a rack connected to the rod or stem of the pump-plunger, a shaft journaled in opposite walls of the measuring-chamber and having at one end a suitable crank or handle, a pinion loosely mounted on said shaft and constantly engaging the rack on the piston-rod, means for clutching the pinion to the shaft, and a delivery-spout leading from the measuring-chamber.

2. In an apparatus for the purpose described, the combination of a measuring-pump having its barrel extended upward to form a measuring-chamber and provided with a valved inlet at its lower end, a rack at the upper end of the rod of the piston or plunger of the pump, a shaft mounted to rotate and move longitudinally in bearings in opposite walls of the measuring-chamber, a pinion loose on said shaft and constantly meshing with said rack, a clutch-disk fast on the shaft and adapted to be moved to and from engagement with said pinion as the shaft is moved longitudinally, and a delivery-spout leading from the measuring-chambes.

3. In an apparatus for the purpose described, the combination of a measuring-pump having its barrel extended upward to form a measuring-chamber and provided with a valved inlet at its lower end, a rack at the upper end of the rod of the piston or plunger of the pump, a shaft mounted to rotate and move longitudinally in bearings in opposite walls of the measuring-chamber, a pinion loose on said shaft and constantly meshing with said rack, a clutch-disk fast on the shaft and adapted to be moved to and from engagement with said pinion as the shaft is moved longitudinally, a delivery-spout leading from the measuring-chamber, and a gage connected at its ends with the upper portion of the pump-barrel and with said delivery-spout, the parts being so proportioned that the quantity of liquid delivered at each revolution of the handle will correspond to the amount indicated by one of the graduations on the gage.

810,533. VALVE MECHANISM FOR STERILIZERS. J EVERETT HALL, Erie, Pa. Filed Feb. 3, 1903. Serial No. 141,689.



Claim.—1. In a sterilizer, the combination of an outer and inner chamber, having closed heads at one end, one of said chambers being nested within the other with the heads adjacent to each other, forming an intermediate chamber, and valve devices arranged in said heads for controlling the admission and exhaust of sterilizing fluid to and from the inner chamber.

2. In a sterilizer, the combination of an outer and inner chamber, having closed heads at one end, one of said chambers being nested within the other with the heads adjacent to each other, forming an intermediate chamber and valve devices arranged in the heads for connecting the chambers and for controlling the exhaust of the sterilizing fluid from the inner chamber.

3. In a sterilizer, the combination of an outer and inner chamber, having closed heads at one end, one of said chambers being nested within the other with the heads adjacent to each other, forming an intermediate chamber, and valve devices arranged in the heads for connecting the chambers and for controlling the exhaust from both chambers.

4. In a sterilizer, the combination with the chamber; of a valve mechanism controlling admission and exhaust from said chamber; an ejector connected with the exhaust; and a single device arranged to actuate the valve mechanism to admit the sterilized medium, exhaust it, and connect the ejector.

5. In a sterilizer, the combination with the chamber; of a single valve mechanism controlling the admission and exhaust of sterilizing medium to and from said chamber; and an ejector controlled by said valve mechanism.

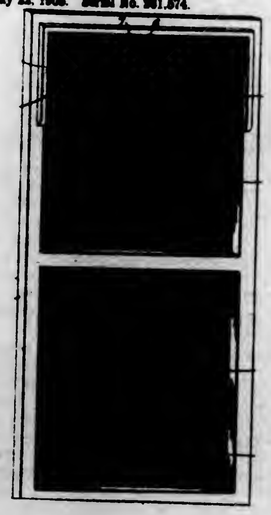
6. In a sterilizer, the combination with the chamber, of a plug-valve controlling the exhaust from said chamber; and an ejector arranged on the plug.

7. In a sterilizer, the combination with the chamber; of a plug-valve controlling the admission and exhaust from said chamber; and an ejector on said plug.

8. In a sterilizer, the combination with the chambers A and B; the valve-body C, said valve-body having the valve-opening c; the way c' connecting the valve-opening with the chamber B; and the way c^4 connecting the valve-opening with the chamber A; and the plug D having the ways d^5, d^7, leading to the chamber A and adapted to be brought into register with the way c'; the annular way d^6 arranged to be brought into register with the way c^3; the way c^3 leading to the exhaust c'; the ejector-nozzle e in the exhaust-passage; and the way c^4 adapted to be brought into register with the way c'.

9. In a sterilizer, the combination with the chambers A and B; the valve-body C arranged between the shells of the chambers A and B, said valve-body having the valve-opening c; the way c' connecting the valve-opening with the chamber B; and the way c^4 connecting the valve-opening with the chamber A; and the plug D having the ways d^5 d^7, leading to the chamber A and adapted to be brought into register with the way c'; the annular way d^6 arranged to be brought into register with the way c^3; the way c^3 leading to the exhaust c'; the ejector-nozzle e in the exhaust-passage; and the way c^4 adapted to be brought into register with the way c'.

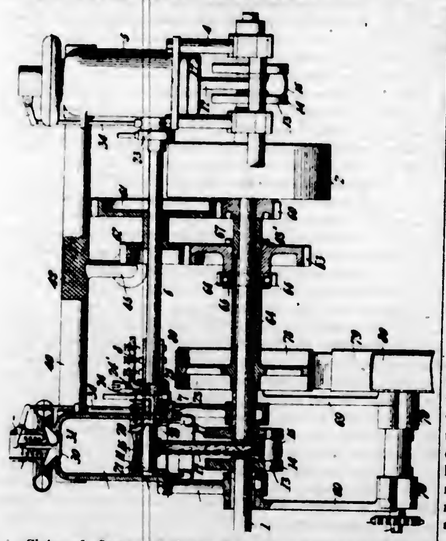
810,534. FLY-SCREEN. WILLIAM B. HART, Greatbend, Kans. Filed May 22, 1905. Serial No. 261,574.



Claim.—1. The combination with a frame, of two screens secured thereto and spaced apart, one of said screens shorter than the other and leaving an unobstructed inlet to the space between said screens at the lower end of the shorter screen, diagonal bars secured to the frame between said screens, a supporting device disposed between said bars and secured at its ends thereto, and a tube secured to said supporting device and passing through one of said screens.

2. The combination with a screen having an opening therein, of guide-bars converging at the opening, a wire coiled between its ends and secured to the guide-bars, and a tube of wire-netting secured to the coil of the wire and projecting through the opening in the screen.

810,535. EXPLOSION-ENGINE. HEINRICH HEINRICH, Spotswood, N. J., assignor of one-half to David D. A. Outcalt, Spotswood, N. J. Filed Apr. 20, 1904. Serial No. 204,130.



Claim.—1. In an explosion-engine, a piston having a peripheral groove forming a water-receptacle, a ported cylinder, a revoluble member having a water-passage in communication with the port, and means for rotating said member.

2. In an explosion-engine, a movable piston having a peripheral groove, a cylinder having a port with which the groove may aline, a revoluble shaft having a water-passage in alinement with the groove, a water-supply means encircling the shaft, and means for rotating said shaft.

3. In an explosion-engine, a cylinder having a port for the passage of water, a grooved piston, a revoluble shaft having a water-passage in alinement with the port, a boxing in which said shaft hangs, and water connections for the boxing, said passage having a laterally or radially extending portion in communication with the interior of the boxing.

4. In combination, a cylinder having a port, a piston having a groove which may aline with the port, a revoluble shaft having a passage-way in part extended on a radial line, an annular groove into which the outer end of the passage opens, a boxing encircling the shaft, and water connections for the boxing.

810,536. TURNING SWITCH WITH LIGHTED HANDLE FOR ELECTRIC LINES. HANS HOLMS, Frankfort-on-the-Main, Germany. Filed Apr. 10, 1905. Serial No. 254,982.

Claim.—An electric switch comprising main contacts connected with the line, a pivotally-mounted switch member for closing circuit through said contacts, said member having relatively long and short contact ends, a lamp for said switch member connected therethrough with one side of the line, and an auxiliary contact connected with the other side, said auxiliary contact being out of the path of said short end and in the path of the long end of said switch member.

810,537. GARMENT-FASTENER. HERBERT A. HOPKINS, West Roxbury, Mass. Filed May 8, 1905. Serial No. 259,440.

Claim.—A two-part garment-fastener comprising a plate adapted to be attached to a garment, said plate having a shank and an elongated head both integral therewith; and a socket member adapted to be fastened to a garment, said socket member having a raised concavo-convex portion adapted to contain said head and provided with an elongated slot for the passage therethrough of said head, said raised portion having an elongated chamber 18 arranged with its longer diameter at right angles to that of said slot, and extending outwardly from the interior of said concavo-convex portion, said chamber adapted to receive said elongated head after said head has been passed through said slot and into the interior of said concavo-convex portion, whereby said parts are securely locked together.

810,538. SPATULA AND CORK-EXTRACTOR. EDWIN B. JELKS, Quitman, Ga. Filed Apr. 11, 1905. Serial No. 255,051.

Claim.—1. The combined spatula and cork-extractor herein described comprising the blade adapted at one end to form a spatula and having its other end forming a cork-extractor, and having its intermediate portion roughened or milled at its edges, the handle-sections lapping upon the opposite sides of the intermediate portion of the blade, the latter projecting laterally beyond the edges of the handle-sections to be grasped by the hand, and devices connecting the handle-sections and the handle-sections and the blade being movable relatively in a longitudinal direction whereby the cork-extractor may be incased between the handle-sections or projected therefrom, substantially as set forth.

2. The combination of the handle-sections, the blade having the spatula at one end, the cork-extractor at the opposite end, an intermediate portion roughened at its edges and slotted longitudinally in said intermediate portion, the handle-sections lapping on opposite sides of the intermediate portion of the blade and made narrower than the said intermediate portion whereby the roughened edges may project beyond the handle-sections, and screws connecting the handle-sections, and extending through the slots in the blade whereby the handle-sections and the blade are movable relatively in a longitudinal direction, substantially as described.

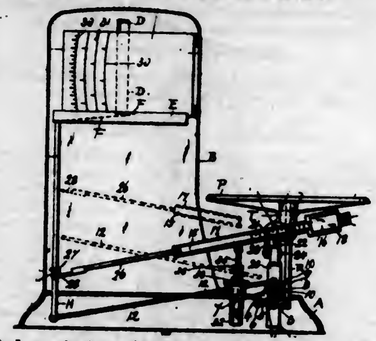
3. The combination with two oppositely-disposed handle-sections of, the blade movable longitudinally between the same and made of a width exceeding that of the handle-sections whereby the longitudinal side edges of the blade will project laterally beyond the handle to form handholds for use in adjusting the blade longitudinally relative to the handle-sections, substantially as, and for the purpose set forth.

810,539. SCALE. ARTHUR JOHNSON, Hamilton, Canada, assignor to Moses Jobbern, Hamilton, Canada. Filed May 3, 1905. Serial No. 258,621.

Claim.—1. In a scale, the combination with a vertically-movable stem, of a scale-pan operatively connected to said stem, a double-faced stationary chart, a housing for said chart having one side open and the other side provided with a vertical slit, and horizontal indicating-arms connected to the stem and disposed on opposite sides of the chart for observation through the slit and the open side of the housing.

2. In a scale, a fulcrumed lever, a lug on the lever, a pendulum pivotally connected to the lug and in vertical line with said fulcrum, a secondary lug on the lever at right angles with the first lug and in proximity to the pendulum, and adjusting means connected to the secondary lug and pendulum.

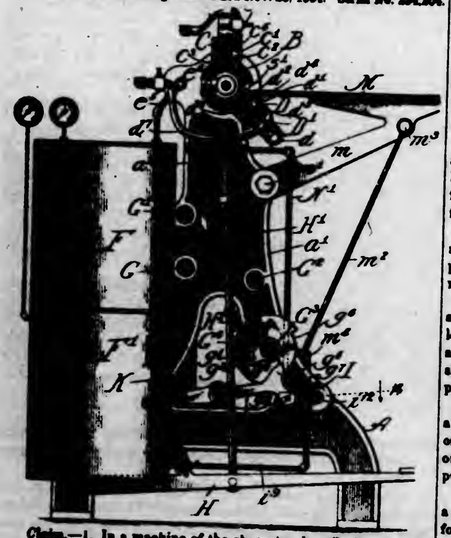
3. In a scale, the combination with a base and a vertically-movable stem, of an indicator operated by said stem, parallel levers pivoted to the stem one above the other and also pivoted to the base, and a scale-pan supported independently of the stem by said parallel levers, whereby the parallel levers operate the indicator.



4. In a scale, the combination with a support or base, of a stem, an indicator operated by said stem, parallel levers pivoted to the base whose pivots are located in vertical alinement with each other, a scale-pan pivoted to one of the levers, a rod connected to the scale-pan, and a link pivoted to the rod in vertical alinement with the point of pivoting the scale-pan to the lever and pivoted to the base in vertical alinement with the point of pivoting the lever to said base.

5. In a scale, the combination with a support or base, of a lever fulcrumed to said base, a scale-pan supported by the lever, a pendulum pivotally connected to the said lever in vertical alinement with the aforesaid fulcrum-point of the lever, and means for adjusting the pendulum laterally to bring the scale to a proper balance.

810,540. LEAF-FLEXING MACHINE. HARRY S. JOURS and WILLIAM G. JOURS, Chicago, Ill. Filed Nov. 26, 1904. Serial No. 234,304.



Claim.—1. In a machine of the character described, means for confining a leaf and flexing it throughout a limited zone, said means varying the place of flexure through very closely adjacent lines and causing a portion of the leaf to shift while the flexing is performed.

2. In a machine of the character set forth, means for confining a leaf and flexing it throughout a limited zone, said means including relatively moving leaf-confining members between which the portion of the leaf under treatment may be shifted and operating to vary the place of flexure through very closely adjacent lines and causing a

3. In a leaf-flexing machine, means for flexing the leaf upon itself and shifting the place of flexure through lines inappreciably removed from each other including leaf-gripping means, for the purpose set forth.

4. In a leaf-flexing machine, means for flexing the leaf upon itself in two directions along very closely related lines, throughout a limited zone including leaf-gripping means, for the purpose set forth.

5. In a leaf-flexing machine, the combination of curved leaf confining and holding devices, and means for producing relative movement of said devices and causing them to apply a shifting flexure to the leaf in one direction and then in the reverse direction over the same area, throughout a given zone, for the purpose set forth.

6. In a leaf-flexing machine, the combination of relatively movable leaf confining and holding devices, operating to bend the leaf upon itself about a very small radius and shift the place of bending, for the purpose set forth.

7. In a leaf-flexing machine, the combination of a rocking member equipped with gripping means, and a leaf confining and holding member in juxtaposition therewith, said members serving to fold a leaf between them and shift the line of flexure throughout a limited zone, for the purpose set forth.

8. In a leaf-flexing machine, the combination of a rocking member equipped with gripping means, and a leaf confining and holding member in juxtaposition therewith equipped with a suction device, said members serving to fold a leaf between them and shift the line of flexure throughout a limited zone, for the purpose set forth.

9. In a leaf-flexing machine, the combination of a rocking member equipped with means for holding the margin of a leaf, and a juxtaposed member coacting with said rocking member equipped with a suction device having orifices opening near its front portion adjacent to said rocking member, whereby a leaf may be drawn between said members, the suction applied to the leaf adjacent to the section to be flexed, and the leaf folded upon itself in the return movement of the rocking member, for the purpose set forth.

10. In a machine of the character described, the combination of a rocking member equipped with jaws having the gripping-space between them accessible in the normal position of rest, and a pair of coacting leaf confining and holding members adjacent to said first-named member and arranged on opposite sides of said space, said rocking member having a range of movement enabling it to carry the leaf between the rocking member and each of said second-named members, for the purpose set forth.

11. In a leaf-flexing machine, the combination of a frame, a table, a jaw-equipped rocking cylinder normally occupying a position with its gripping-plane adjacent to the rear edge of said table, and a pair of leaf confining and holding members arranged above and below the plane of said table, for the purpose set forth.

12. In a machine of the character set forth, the combination with a rocking member equipped with means for holding a margin of a leaf, a pair of juxtaposed concaves, and suction devices having orifices opening near the front edges of the concaves, for the purpose set forth.

13. In a machine of the character set forth, the combination of a rock-cylinder equipped with jaws, means for actuating the jaws, a pair of concaves, suction devices connected with said concaves, and means for controlling the suction, for the purpose set forth.

14. In a machine of the character described, the combination of a rock-cylinder equipped with pneumatically-actuated jaws, and a leaf confining and holding member adjacent to said rock-cylinder, and operating in conjunction with the cylinder to flex a leaf and shift the place of flexure uniformly throughout a given zone, for the purpose set forth.

15. In a machine of the character set forth, the combination of a jaw-equipped rock-cylinder having normally open jaws, and a pair of leaf confining and holding members adjacent to said cylinder and on opposite sides of the normal gripping-plane of the jaws, for the purpose set forth.

16. In a machine of the character set forth, the combination of a jaw-equipped rock-cylinder having normally open jaws, means for closing the jaws, and a pair of concaves adjacent to the cylinder on opposite sides of the normal gripping-plane of the jaws equipped with suction devices having orifices at the front portions of said second-named members, for the purpose set forth.

17. In a machine of the character set forth, the combination of a rock-cylinder equipped with grippers and pneumatic actuating means for the grippers, a leaf confining and holding member equipped with a suction device, a pump, and pressure and vacuum chambers connected with said pump and respectively joined to said pneumatic actuating means and said suction devices, for the purpose set forth.

a rock-cylinder equipped with jaws, a piston movable longitudinally of the rock-cylinder and serving in the actuation of the jaws, and a leaf confining and holding member serving in conjunction with the rock-cylinder to bend a leaf upon itself and vary the line of flexure, for the purpose set forth.

19. In a machine of the character set forth, the combination of a cylinder equipped with gripping-jaws, a jaw-actuating piston movable longitudinally in said cylinder, and a leaf confining and holding member adjacent to the cylinder and acting in conjunction with the cylinder to fold a leaf upon itself and vary the line of flexure said last-named member and the cylinder being relatively movable, for the purpose set forth.

20. In a machine of the character set forth, the combination of a rock-cylinder provided with gripping-jaws and equipped internally with cylinders, a jaw-actuating piston, pipes communicating through the journals of said rock-cylinder with said internal cylinders, a valve controlling said pipes, means for actuating said valve in one direction, and a leaf confining and holding member coacting with said rock-cylinder, for the purpose set forth.

21. In a machine of the character set forth, the combination of a rock-cylinder equipped with grippers, means for actuating the grippers, means for actuating the rock-cylinder, a leaf confining and holding member adjacent to the rock-cylinder, and mechanism for controlling the movements of said cylinder comprising means for setting the cylinder in motion, and automatically-actuated means for stopping the cylinder, for the purpose set forth.

22. In a machine of the character set forth, the combination of a rock-cylinder equipped with grippers, means for actuating the grippers, means for actuating the rock-cylinder, a leaf confining and holding member adjacent to the rock-cylinder, and mechanism for controlling the movements of the cylinder and the actuation of its grippers, comprising means for governing the closing of the grippers of the cylinder and setting the machine in motion, and automatic means for governing the stopping of the cylinder and opening the grippers, for the purpose set forth.

23. In a machine of the character set forth, the combination of a rock-cylinder equipped with grippers, pneumatic means for closing said grippers, a leaf confining and holding member adjacent to said cylinder, and controlling mechanism comprising a normally inactive shaft connected with said cylinder, a continuously-rotating member, a clutch for connecting the normally inactive shaft, a suitably-actuated cam, means for actuating said cam to operate said clutch, and means for automatically continuing the movement of said cam, whereby the cam serves to release said clutch after the machine has completed its cycle of operations, for the purpose set forth.

24. In a machine of the character set forth, the combination with a rock-cylinder provided with gripping-jaws and pneumatic means for actuating the same, a leaf confining and holding member adjacent to said cylinder, a valve controlling the admission to said cylinder, a normally inactive shaft connected with said cylinder, a clutch through the medium of which said shaft may be actuated, and mechanism whereby said cam serves, in its initial movement, to actuate said valve, and thereafter to throw said clutch into operation, and finally to release said clutch after the machine has completed its cycle of operations, for the purpose set forth.

25. In a machine of the character set forth, the combination of a rock-cylinder equipped with gripping-jaws, pneumatic means for actuating said jaws, a valve controlling the admission to said pneumatic means, concaves adjacent to said cylinder equipped with suction devices, a valve controlling said suction devices, means for actuating said cylinder, and mechanism manually actuated in the operation of starting the machine and automatically actuated in the operation of stopping the machine, whereby, in a cycle of operations of the machine, said jaws are closed after a leaf is introduced, said cylinder set in motion, the suction applied alternately to said suction devices, the cylinder stopped, and the jaws released, for the purpose set forth.

26. In a machine of the character set forth, the combination with a rock-cylinder, of a pair of concaves coacting therewith and equipped with suction devices, a valve controlling said suction devices, and valve-actuating means operated from said cylinder, for the purpose set forth.

27. In a machine of the character set forth, the combination of a rock-cylinder having a jaw equipped with trunnions and a relatively movable jaw, actuating means for the cylinder connected with one of said trunnions, actuating means for said second-named jaw, and a leaf confining and holding member adjacent to said cylinder, for the purpose set forth.

28. In a machine of the character set forth, the combination of a rock-cylinder having a jaw equipped with trunnions and a jaw pivotally supported on said first-named jaw, a piston movable longitudinally in said cylinder and equipped with jaw-actuating means, means connected with one trunnion of the cylinder for actuating the cylinder, and a leaf confining and holding member adjacent to said cylinder, for the purpose set forth.

29. In a machine of the character set forth, the combination of a rock-cylinder and a concave adjacent thereto equipped with a suction device, said suction device being provided with means for limiting the extent whereat the suction is applied, whereby leaves of different width may be treated, for the purpose set forth.

30. In a machine of the character set forth, the combination of a rock-cylinder provided with pneumatically-actuated jaws, concaves adjacent thereto equipped with suction devices, and actuating and controlling means, comprising a normally inactive shaft, a clutch for the same, a shaft geared to said first-named shaft, a cam mounted thereon and capable of limited movement with relation thereto, a cam-lever, manual means for initially moving said cam, and valves controlling the pneumatic pressure and the suction, for the purpose set forth.

31. In a leaf-flexing machine, the combination with leaf confining and holding members, of a normally inactive shaft from which one of said members is actuated, a clutch therefor, a second shaft geared to the first-named shaft, a cam having lost-motion connection with said second-named shaft, a cam-lever, a valve operated thereby, and a trip on said second-named shaft controlling said clutch, for the purpose set forth.

32. The combination of a rock-cylinder having pneumatically-actuated gripping-jaws, pipes leading to said cylinder, a valve controlling said pipes, a foot-lever controlling said valve, and a leaf confining and holding member adjacent to said cylinder, for the purpose set forth.

33. The combination of a rock-cylinder having pneumatically-actuated gripping-jaws, a valve controlling the admission thereto, concaves equipped with suction devices, a valve controlling the suction devices, a normally inactive shaft joined to said rock-cylinder, a second shaft geared to said first-named shaft, a clutch for the first-named shaft controlled by the second-named shaft, a cam having lost-motion connection with the second-named shaft, a cam-lever coacting with said cam and controlling said first-named valve, means for moving said cam to operate said first-named valve and said clutch, and actuating means for the second-named valve, for the purpose set forth.

34. In a leaf-flexing machine, the combination with a frame member having air-passages opening at a flat surface, a spring-held rotary valve having a flat surface engaging said first-named surface, an oscillating member equipped with leaf-gripping jaws, and pneumatic jaw-actuating means connected with the air-passages of said frame member, for the purpose set forth.

35. The combination of a rock-cylinder equipped with gripping-jaws, means for turning said rock-cylinder, a concave equipped with a suction device, a valve controlling the suction, and gear connection between said rock-cylinder and suction-controlling valve, for the purpose set forth.

36. The combination of a rock-cylinder equipped with grippers, a coacting leaf-confining member equipped with a device for holding a leaf at a point near the area to be treated, and mechanism serving to close said grippers, turn the cylinder, apply holding force to the leaf through said second-named member, reverse the cylinder, and open the grippers, for the purpose set forth.

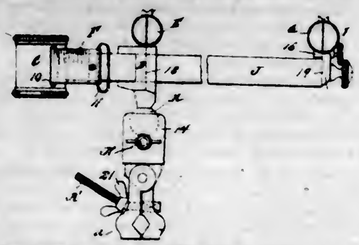
37. The combination of a rock-cylinder equipped with grippers, a pair of coacting leaf confining and holding members, and mechanism serving to close the grippers, impart to said cylinder a plurality of reciprocations in each direction from its normal position of rest, and then open the grippers, for the purpose set forth.

810,541. TELEMETER. ALPHONSE JOOSS, Forest, near Brussels, and ADHÉMAR MINCKWITZ, Brussels, Belgium. Filed Mar. 6, 1905. Serial No. 248,566.

Claim.—1. A telemeter comprising a plurality of telescoping tubes, a sight-tube mounted on the outer tube at right angles thereto, a like sight-tube mounted on the end of the innermost telescoping tube and at an angle to the first sight-tube and means to measure the distance between the two tubes, substantially as described.

2. In a telemeter, a plurality of telescoping tubes, a supporting member on and adjustable along the outer tube, a sight-tube fixed on

sight-tube and a measure for the distances between the two tubes graduated to read distances of the objects sighted.



3. In a telemeter, a plurality of telescoping tubes, a supporting member on and adjustable along the outer tube and having a measuring edge, a sight-tube fixed on the member at right angles to the telescopic tubes and in alinement with the measuring edge, a plate having a measuring edge fixed on the end of the innermost telescopic tube, a sight-tube in alinement with the edge on said plate, means on the plate to angularly adjust the second sight-tube, and means to measure the distance between the measuring edges.

4. In a telemeter, a plurality of rectangular telescoping tubes, a supporting member on and adjustable along the outer tube, and having a measuring edge thereon, a tape-case, and tape on one end of the outer tube, a sight-tube mounted on the member in vertical alinement with said edge at right angles to the telescoping tubes, a ball-and-socket joint on the member and a clamp on the ball-and-socket joint, a plate having a forked extension fixed on the end of the innermost telescoping tube and having a measuring edge, a sight-tube mounted on the plate in vertical alinement with the measuring edge and means in the forked extension to angularly adjust the second sight-tube, substantially as and for the purpose set forth.

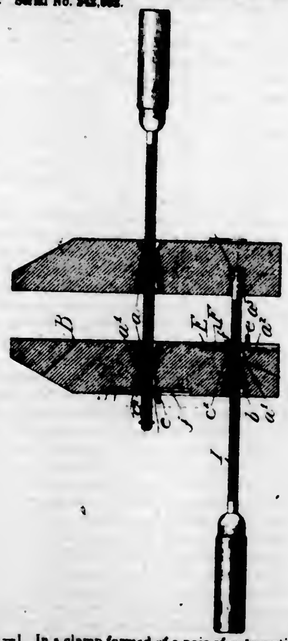
810,542. **EXHAUST-MUFFLER.** WILLIAM R. KAHLENBERG, Two Rivers, Wis. Filed Sept. 9, 1905. Serial No. 277,775.

Claim.—1. A muffler consisting of a closed drum provided with heads at either end thereof, exhaust inlet or outlet openings in the heads, an inner jacket of less diameter than the drum in communication with the exhaust and inlet openings, peripheral openings in the jacket adjacent to its ends, and a valve fitted in said jacket between the peripheral openings.

2. A muffler consisting of a drum having an inner jacket of less diameter than said drum, inlet and outlet exhaust-openings therefor, two series of openings at either end of the jacket, a valve fitted therein between the series of openings, a stem for said valve, a lever mounted on the stem, a boss secured to the drum concentric with the valve-stem, and a friction-band mounted on said boss and connected to the handle.

3. A muffler consisting of a drum having an inner jacket of less diameter than the drum, inlet and outlet exhaust-openings therefor, two series of openings at either end of the jacket communicating with the space between the latter and said drum, a valve fitted in said jacket intermediate of the two series of openings, a stem for said valve, a boss secured to the outside of the aforesaid drum through which the valve-stem projects, a lever secured to the valve-stem adjacent to the boss and provided with a lug, a split ring fitted over said boss having ears engaging the said lug, and a hand-wheel in threaded engagement with one of the ears, whereby the tension of the aforesaid split ring is adjusted upon the boss and the lever secured thereto.

810,543. **CLAMP.** HERMAN A. KNOKE, Chicago, Ill. Filed Jan. 25, 1905. Serial No. 243,693.



Claim.—1. In a clamp formed of a pair of coöperating jaws provided with operating-screws, a screw-bearing comprising a nut formed of separable sections rotatably supported on a jaw, and means for separating said sections to free the screw and for bringing them together to adapt the screw to engage operatively therewith, for the purpose set forth.

2. In a clamp formed of a pair of coöperating jaws provided with operating-screws, a screw-bearing comprising a nut formed of longitudinally-separable sections rotatably supported on a jaw, and means for separating said sections to free the screw and for bringing them together to adapt the screw to engage operatively therewith, for the purpose set forth.

3. In a clamp formed of a pair of coöperating jaws provided with operating-screws, a screw-bearing comprising a nut formed of two separable sections rotatably supported on a jaw, and means for separating said sections to free the screw and for bringing them together to adapt the screw to engage operatively therewith, for the purpose set forth.

4. In a clamp formed of a pair of coöperating jaws provided with operating-screws, a screw-bearing comprising a nut formed of two separable sections rotatably supported on a jaw, a tongue on one of said sections and a groove in the other section to coöperate with said tongue, and means for separating said sections to free the screw and for bringing them together to adapt the screw to engage operatively therewith, for the purpose set forth.

5. In a clamp formed of a pair of coöperating jaws provided with operating-screws, a screw-bearing secured to one of said jaws, comprising a nut formed of separable sections rotatably housed in the jaw transversely thereto, and an aperture in the other jaw to register with said screw-opening, and means for separating said sections to free the screw and for bringing them together to adapt the screw to engage operatively therewith, for the purpose set forth.

6. In a clamp, the combination of a pair of coöperating jaws provided with operating-screws, a screw-bearing comprising a nut formed of separable sections provided with transverse grooves, and a cam-frame confined at its arms in said grooves and operative to spread said sections apart and bring them together, for the purpose set forth.

7. In a clamp formed of a pair of coöperating jaws provided with operating-screws, a screw-bearing comprising a nut rotatably housed in a jaw and formed of separable sections endwise abutting to form the threaded opening, and cam mechanism engaging said nut to spread the sections apart and force them together.

8. In a clamp, the combination of a pair of coöperating jaws, screw-bearings secured to one of said jaws, each comprising a nut rotatably supported on said jaw and composed of two sections forming the threaded opening between them, cams engaging said sections for longitudinally separating them and bringing them together, and operating-screws for the jaws working in said screw-bearings.

9. In a clamp, the combination of a jaw, screw-bearings journaled in said jaw transversely thereto near its center and near its rear end, respectively, each comprising a nut formed of two longitudinally-separable sections, cams for separating said sections, a companion jaw coöperating with said first-named jaw, provided near its center with a transverse aperture and near its rear end with a socket, screws for operating said jaws, one screw passing through said aperture and screw-bearing opposite thereto and the other screw passing through the other said screw-bearing and releasably confined in said socket, for the purpose set forth.

10. A clamp comprising, in combination, a pair of jaws, one of said jaws having screw-openings respectively near its center and rear end, with openings forming nut-housings extending across said screw-openings respectively near the back and face of the jaw, nuts rotatably confined in said housings each nut being formed of separable sections, cams supported on said jaw to operatively engage said nuts for separating and bringing together said sections, the other jaw having screw-openings to register with those in the first-named jaw, and screws working in opposite directions in said jaw-openings through said nuts, for the purpose set forth.

11. A clamp comprising, in combination, a pair of jaws, one of said jaws having screw-openings respectively near its center and rear end, with openings forming nut-housings extending across said screw-openings and containing bushings, nuts rotatably confined in said bushings, each nut being divided through its threaded opening into separable sections, cams supported on said jaw to operatively engage said nuts for separating and bringing together said sections, the other jaw having screw-openings to register with those in the first-named jaw, and screws working in opposite directions in said jaw-openings through said nuts, for the purpose set forth.

12. A clamp comprising, in combination, a pair of jaws, one of said jaws having screw-openings respectively near its center and rear end, with openings forming nut-housings extending across said screw-openings, nuts confined in said nut-openings, each nut being divided through its threaded opening into two separable sections, said sections being provided with cam-receiving grooves, a cam for each nut, comprising a cam-frame adjustably confined on said jaw with its arms engaging the sections of a nut at said grooves therein, the other jaw having screw-openings to register with those in the first-named jaw, and screws working in opposite directions in said jaw-openings through said nuts, for the purpose set forth.

13. A clamp comprising, in combination, a pair of jaws, one of said jaws having screw-openings respectively near its center and rear end, with openings forming nut-housings extending across said screw-openings, nuts confined in said nut-housings, each nut being divided through its threaded opening into two separable sections, said sections being provided with cam-receiving grooves, a cam for each nut comprising a cam-frame adjustably confined on said jaw with its arms engaging the sections of a nut at said grooves therein, the other jaw having a screw-opening between its ends and a socket near its rear end, a screw working in one direction through said central openings in both jaws and through the nut in one said opening, a headed screw working through the other nut in the jaw provided therewith and entering the socket in the opposite jaw, and means for releasably confining said headed screw in said socket, for the purpose set forth.

810,544. **CABINET.** ERIK L. KRAG, Chicago, Ill., assignor to Krag Imperial Cabinet Company, a Corporation of Illinois. Filed Jan. 31, 1903. Renewed June 21, 1905. Serial No. 266,343.

Claim.—1. In a cabinet, in combination, a base; rods extending upwardly therefrom; a plurality of shelves; and a series of partitions adapted to be strung upon said rods and to be interposed between said shelves.

2. In a cabinet, in combination, a base; rods extending upwardly therefrom; a bottom plate having openings coinciding with said rods; a series of shelves also having openings coinciding with said rods; and partitions adapted to be strung upon said rods and to be interposed between said shelves.

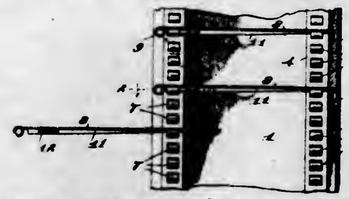
3. In a cabinet, in combination, a base; rods extending upwardly therefrom; a bottom plate having openings coinciding with said rods; a series of shelves also having openings coinciding with said rods; partitions adapted to be strung upon said rods and to be interposed between said shelves; and means for holding said shelves and partitions upon said rods.

4. In a cabinet in combination, a base having a back bar, a front bar and end bars; rods extending through said back bar and said front bar; end walls and a back wall for said cabinet; a bottom plate having openings coinciding with said rods; a series of shelves also having openings coinciding with the rods; partitions having integral sleeves adapted to receive said rods, said partitions being placed between adjacent shelves to space said shelves upon said rods; and means on the rods for clamping the shelves, partitions and base together.

5. In a cabinet, in combination, a base; rods extending upwardly therefrom; end walls and a back wall; a plurality of shelves on said rods, said shelves being provided with flanges at their ends and rear edges, which flanges are secured to said end walls and back wall; and partitions interposed between adjacent shelves, said partitions having sleeves adapted to receive said rods.

6. In a cabinet, in combination, a base comprising a back bar and a front bar; rods extending through said back bar and said front bar; end walls and a back wall; a bottom plate having openings coinciding with said rods; a plurality of shelves also having openings coinciding with the rods, said shelves being provided with flanges at their ends and rear edges, which flanges are secured to said end walls and back wall; partitions interposed between adjacent shelves, said partitions having integral sleeves adapted to receive said rods; and means on the rods for clamping the shelves, partitions and base together.

810,545. **METALLIC CABINET.** ERIK L. KRAG, Chicago, Ill., assignor to Krag Imperial Cabinet Company, a Corporation of Illinois. Filed Jan. 31, 1903. Renewed June 21, 1905. Serial No. 266,344.



Claim.—1. A cabinet having side walls, each of said walls being provided with two strips carrying a vertical series of ears cut from the substance of said strips and bent inward therefrom, in combination with a shelf adapted to rest upon said integral ears; and a spring secured to said shelf and adapted to engage one of said ears to prevent accidental forward displacement of said shelf.

2. In a cabinet, in combination, two sides walls, each provided with a vertical series of ears; a shelf adapted to rest upon said ears, said shelf having side flanges adapted to lie in the rear of said ears; and a spring on one of said side flanges, the free end of which spring is adapted to engage one of said ears to prevent accidental forward displacement of said shelf.

3. In a cabinet, in combination, two side walls, each provided with two strips carrying a vertical series of ears cut from the substance of said strips and bent inward therefrom; a shelf adapted to

rest upon said integral ears, said shelf having side flanges adapted to lie in the rear of said ears; and a spring on one of said side flanges, the free end of which spring is adapted to engage one of said ears to prevent accidental forward displacement of said shelf.

810,546. FIFTH-WHEEL. JOSEPH KRENZER, Superior, Wis., assignor of one-half to Thomas J. Solon, Superior, Wis. Filed July 3, 1905. Serial No. 268,164.

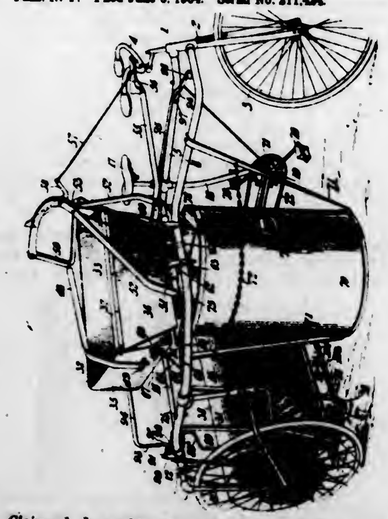
Claim.—1. In a fifth-wheel, a pair of superposed rings, each forming a complete annulus, and each having an integral cross-bar for connection with the running-gear, the lower ring being approximately V-shaped in cross-section, and the horizontal contacting faces of the two rings being coextensive in width, the upper ring having a marginal flange encircling the tapered outer edge of the lower ring, and serving to maintain the rings in proper relative positions.

2. In a fifth-wheel construction, an upper grooved ring having an integral cross-bar arranged for connection to a portion of the running-gear, and a lower ring also having an integral cross-bar, the lower ring being approximately V-shaped in cross-section and being split or divided to permit its introduction within the groove of the upper ring.

3. As a new article of manufacture, a fifth-wheel formed of a bar of metal split and opened out to form an unwelded ring having a friction-surface of uniform character throughout.

4. As a new article of manufacture, a fifth-wheel formed of a bar of metal, split and opened out to form an unwelded ring, the end portions of the bar being split to form arms that are arranged in continuous alinement and form an integral part of said ring.

810,547. SELF-LOADING CART. ROBERT C. MEEKINS, Glens Falls, N. Y. Filed June 6, 1904. Serial No. 211,494.



Claim.—1. In combination, a wheeled frame having a rider's seat, a dirt-receptacle supported by the frame at a point to one side of the seat, a dirt-gathering means in a plane to the rear of the seat, a dirt-receiver for conveying the dirt from the gathering means to the receptacle and adjustable to a dumping position above the receptacle, and within reach of said seat.

2. In combination, a rider-propelled wheeled frame, a dirt-receptacle supported by the frame at a point to one side of the rider's seat, a dirt-gathering means, a dirt-receiver movable between the gathering means and the receptacle, and a receiver hoisting and lowering means adjacent to and operable from the rider's seat.

3. In combination, a rider-propelled wheeled frame, a dirt-gathering element supported by the frame, a rider's seat and a dirt-receptacle arranged side by side in front of the dirt-gathering element, a dirt-receiver movable between the dirt-gathering element and the receptacle, and a receiver elevating and lowering means adjacent to and operable from the rider's seat.

4. In a device of the class described, a wheel-supported frame, a cage supported by said frame, a receiver vertically movable in and supported by said cage, and tiltable at the upper limit of its movement and means for raising and lowering said receiver.

5. In a device of the class described, a wheel-supported frame, a cage connected with said frame and including hangers having stirrups at their lower ends and side bars connecting the free ends of said stirrups with the frame, and a receiver normally supported upon said stirrups.

6. A wheel-supported frame, a cage connected with said frame and including a pair of hangers having stirrups and supporting-bars connecting the free end of said stirrups with the frame, a receiver normally supported upon said stirrup and having wear-strips adapted to engage said stirrups and hangers, and means for vertically moving said receiver with its wear strips or shoes in contact with the hangers.

7. A wheel-supported frame, a cross-bar connecting the side members of said frame, hangers depending from said cross-bar and having offset shoulders and rearwardly-extending stirrups, side bars connecting the free ends of said stirrups with the frame, a cross-bar connecting the lower ends of the side bars, and a receiver normally supported upon the stirrups and having an open rear side and a rearwardly-projecting lip normally resting upon the cross-bar connecting the lower ends of the side bars.

8. A wheel-supported frame, a cross-bar connecting the side members of said frame, hangers depending from said cross-bar and having offset shoulders and rearwardly-extending stirrups having upturned rear ends, side bars depending from the side members of the frame and connected by a cross-bar extending beneath the upturned rear ends of the stirrups, a receiver consisting of a box having rounded bottom edges engaging the rounded ends of the stirrups and provided with a rearwardly-extending lip supported upon the cross-bar connecting the supporting side members, and means for manipulating said receiver.

9. A supported cage including hangers having offset lower ends and rearwardly-extending stirrups having upturned ends, side bars supporting the rear ends of said stirrups and connected at their lower ends by a cross-bar, a receiver supported by the stirrups and having a rearwardly-extending lip and a conveyer-pan connected pivotally with the side bars and normally supported upon the lip of the receiver.

10. A supported cage, a receiver vertically movable in said cage and having an open rear side and a bottom provided with a rearwardly-extending lip, a lid hinged at the upper corners of said receiver, and means for elevating the receiver and for tilting the latter as it approaches the upper limit of its movement.

11. A wheel-supported frame, a cage depending from and supported by said frame, a receiver vertically movable in said cage, and tiltable at the upper limit of its movement and means for guiding said receiver into and out of contact with hangers constituting part of the cage, in contact with which the receiver is guided upwardly and downwardly.

12. A wheel-supported frame, a receiver-supporting cage depending from said frame, a receiver vertically movable in said cage, a yoke pivotally connected with said receiver, an operating-lever connected with said yoke, and a locking device connected with said lever to retain the receiver in a lowered, supported position to prevent it from jolting.

13. A wheel-supported frame, a receiver-supporting cage connected with and depending from said frame, a receiver vertically movable in said cage, a yoke connected pivotally with the receiver, an operating-lever connected pivotally with the yoke, a bell-crank lever terminating at one end in a hook adapted to engage a fixed portion of the frame to thereby lock the operating-lever, the yoke and the receiver when the latter is in a lowered position, a hand-lever connected with the operating-lever, a grip pivotally connected with said hand-lever, and a rod connecting said grip with the free end of the bell-crank lever having the locking member.

14. A wheel-supported frame, a suitably-supported, vertically-movable receiver having an open rear side and a lid hinged at the upper corners thereof, means for elevating said receiver, and movable means for engaging and tilting said receiver as it approaches the upper limit of its movement to cause the lid to swing open.

15. A wheel-supported frame, a suitably-supported, vertically-movable receiver having a hinged lid and provided with laterally-extending pins, means for elevating said receiver, and spring-supported, pivotally-mounted hook members disposed in the path of said pins to engage the latter, thereby causing the receiver to be tilted as it approaches the upward limit of its movement.

16. A wheel-supported frame, a vertically-movable receiver, means for supporting and guiding the latter, operating means for said receiver including a yoke pivotally connected therewith, an operating-lever fulcrumed upon the frame and connected pivotally with said yoke, and a hand-lever connected with the operating-lever, a locking device connected with the operating-lever for retaining the receiver in a lowered position, means connected with the hand-lever for releasing said locking device when the receiver is to be started in an upward direction, and means for tilting the receiver as it reaches the upper limit of its movement.

17. A wheel-supported frame, a vertically-movable receiver, means for supporting said receiver, including hangers depending from a cross-bar of the frame and having forwardly-extending brackets, spring-actuated hook members connected with the frame cross-bar and pins extending laterally from the receiver in the path of said hook members to be engaged thereby during the upward movement of the receiver which is thereby tilted as it approaches the upper limit of its movement.

18. A wheel-supported frame, including a side member having a transversely-disposed portion, box members supported thereon, a rock-shaft mounted upon said box members, clips connecting the rock-shaft and box members with the frame member, converging arms connected with said rock-shaft and having bent ends, said rock-shaft and arms constituting an operating-lever, a vertically-movable receiver, a yoke connected pivotally with the latter and having an arm connected pivotally with the bent arm of the operating-lever, and spring means to assist the operating-lever in overcoming the weight of the receiver.

19. A wheel-supported frame, a rock-shaft pivotally connected therewith and having converging arms constituting an operating-lever, a pivotally-mounted receiver supported by said lever, a hand-lever connected with the operating-lever, spring means for assisting the latter in overcoming the weight of the receiver, and means for causing the latter, when elevated, to be tilted as it approaches the upper limit of its movement.

20. A wheel-supported frame, an operating-lever connected pivotally with the same, a pivotally-supported receiver connected pivotally with the operating-lever, means connected with the latter for raising and lowering the receiver, means for tilting the latter as it approaches the upper limit of its movement, and means connected with the operating-lever, for locking the receiver at the lower limit of its movement.

21. A wheel-supported frame, an operating-lever connected pivotally therewith, a receiver connected with and carried pivotally by said operating-lever, means connected with the latter for raising and lowering the receiver and for tilting the same as it approaches the upper limit of its movement, suitably-supported hoppers to receive the material discharged from the receiver, and a receptacle supported removably below said hoppers to receive the material discharged from the latter.

22. A wheel-supported frame, an operating-lever, a vertically-movable receiver supported pivotally by said lever, means for tilting said receiver as it approaches the upper limit of its movement, means, supported by the frame, for receiving the material discharged from the receiver, and intermediate hoppers constituting guides to convey material from the receiver into the receptacle.

23. A wheel-supported frame, a receptacle supported detachably thereon, a cross-bar forming a part of said wheel-supported frame, and a hopper-carrying frame hingedly connected with said cross-bar and provided with hoppers adapted to discharge into the receptacle.

24. A wheel-supported frame, a receptacle supported thereby, a rock-shaft connected with a side member of the frame and provided with arms constituting an operating-lever, a clip serving to connect said rock-shaft with the frame member and having a rearwardly-extending plate, a hopper-carrying frame connected hingedly with the wheel-supported frame and adapted to be supported upon the rearwardly-extending clip-plate, and a vertically-movable receiver adapted, when elevated, to discharge over said hoppers into the receptacle.

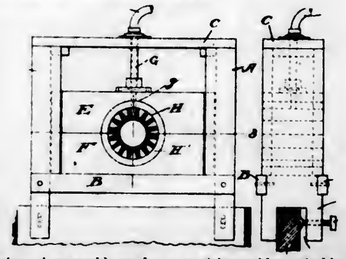
25. A wheel-supported frame, a receiver-supporting cage connected with said frame, a vertically-movable receiver having an open rear side, a pivotally-mounted conveyor-pan disposed in proximity to the open rear side of the receiver, a gathering member cooperating with said conveyor-pan to discharge material into the receiver, a casing for said gathering member, and a flexible strip connected with the receiver and abutting upon said casing when the receiver is at the lower limit of its movement.

26. A frame, guiding and transporting wheels for said frame, a seat, a crank-shaft having pedals adapted to be operated by a person occupying the seat, means for transmitting motion from said crank-shaft to one of the transporting-wheels, a rotary gathering member, links mounted pivotally upon the shaft of the transporting-wheel and having bearings for the shaft of the rotary gathering member, means for transmitting motion from the driven transporting-wheel to said shaft, and means for throwing said motion-transmitting means into operation and simultaneously lowering the arms carrying the gathering member, and vice versa.

27. A machine of the class described including a rotary gathering member, a vertically-movable receiver, and a pan for conveying material into the receiver, said pan being hingedly connected with a receiver-supporting cage, means for simultaneously raising or lowering the rotary gathering member and the conveyer-pan, and means for, at the same time, throwing out of or into operation means for transmitting motion from a transporting-wheel of the machine to the rotary gathering member.

28. In an organized machine of the class described, a vertically movable and tiltable receiver having an open rear side and a rearwardly-extending lip, a conveyer-pan normally resting upon said lip, a rotary gathering element coöperating with the conveyer-pan to discharge material into the receiver, means for effecting the vertical adjustment, simultaneously, of the rotary gathering member and the conveyer-pan, means for positively limiting the downward movement of the free edge of the latter, means for transmitting motion to the rotary gathering member from a transporting-wheel of the machine, and means including vertical, resilient rods for throwing into and out of gear said motion-transmitting means.

810,548. VEGETABLE-WASHER. LOUIS MEYER, Dayton, Ky. Filed Feb. 20, 1905. Serial No. 246,514.



Claim.—A vegetable-washer comprising guides, suitably braced in parallel position to each other, means for clamping said guides to a suitable support, brush-holders sliding in said guides, substantially circular brushes secured to said brush-holders, adapted to form a circle when the brush-holders are brought together, a water-pipe leading to one of said brushes, and means for supplying water to said pipe, substantially as described.

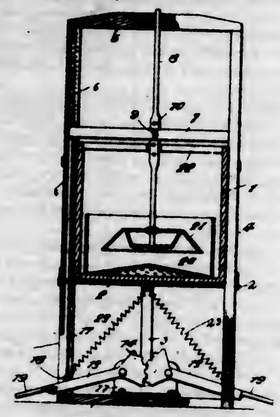
810,549. WASHING-MACHINE. ARATHE G. MOSCHEL, Dallas, Tex., assignor of one-fourth to Sam Freshman and one-fourth to E. J. Reiss, Dallas, Tex. Filed June 10, 1905. Serial No. 264,701.

Claim.—1. In a washing-machine the combination of a tub, means for supporting same in a raised position, upright members extending above the tub on opposite sides thereof, a cross-bar slidably mounted above the tub and directed in its movements by said upright members, a plunger attached to the cross-bar, a pair of treadles located beneath the tub, rods connecting the cross-bar and the treadles, and springs to hold the treadles normally in a raised position.

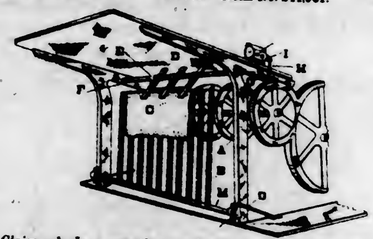
2. In a washing-machine the combination of a tub, means for supporting same in a raised position, upright members extending above the tub on opposite sides thereof, a cross-bar slidably mounted above the tub within grooves in the said upright members, a plunger attached to the cross-bar, a pair of treadles located beneath the tub and operating in slots in the upright members, and rods connecting the ends of the cross-bar and the treadles and located within the upright members.

3. In a washing-machine the combination of a tub, means for supporting same in a raised position, upright members extending above the tub on opposite sides thereof, a cross-bar slidably mounted above the tub within grooves in the said upright members, a plunger

sejached to the cross-bar, a pair of treadles beneath the tub which operate in unison and pass through slots in the upright members, rods connecting the ends of the cross-bar and the treadles and located within the upright members, and springs to hold the treadles normally in a raised position.



810,550. COUNTING MECHANISM. HENRY C. MCCALLUM, Montreal, Canada. Filed Feb. 9, 1905. Serial No. 244,961.



Claim.—1. In a counting mechanism, a series of spaced feed-arms mounted on a common axle, a series of spaced contact-arms also mounted on a common axle, said contact-arms positioned to occupy the spaces between said feed-arms, a registering means attached to the contact-arm axle and independently-operated means for feeding articles against the contact-arms.

2. In a counting mechanism, a series of contact-arms mounted on a common axle, registering mechanism mounted adjacent thereto, means for actuating the registering mechanism by the oscillation of said axle in combination with a series of feeding-arms positioned to occupy the spaces between said contact-arms and operated independently of said counting mechanism.

3. In a printing-machine, a series of spaced feed-arms mounted on a common axle, means for supplying articles to be counted to said feed-arms, in combination with a registering mechanism actuated by the oscillation of an axle carrying contact-arms spaced between the feed-arms.

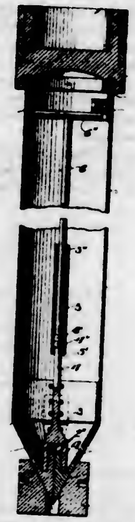
4. In a mechanism for printing and counting articles, a series of spaced feed-arms, means for applying articles to be counted to said feed-arms, in combination with a counting mechanism actuated by the oscillations of an axle carrying contact-arms arranged to be free from interference with the feeding-arms and adapted for operation only by contact with articles carried thereon, substantially as described.

810,551. PILE-TUBE. JOHN MCGRANAHAN, Rexboro, Pa. Filed June 29, 1905. Serial No. 267,946.

Claim.—1. A pile-tube comprising a body and a point consisting of cone-sections hinged to said body, in combination with the internal means for locking said sections together.

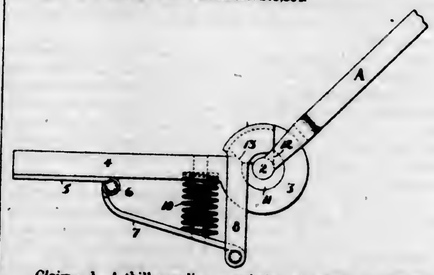
2. A pile-tube comprising a body and a point having separable sections hinged to said body, said sections having projections thereon, in combination with means for engaging said projections to lock said sections together.

3. A pile-tube comprising a body and a point having separable sections hinged to said body, said sections having projections within them, in combination with a shoe for engaging said projections to lock said sections together, and means for exerting a hammer-blow in setting and removing said shoe.



4. A pile-tube comprising a body having a point composed of hinged sections with projections thereon, a shoe with a stem thereon for engaging said projections, a handle having a stem thereon, and coupling mechanism connecting said stems in movable relation to each other.

810,552. THILL-COUPLING. JOHN A. MCLAUGHLIN, San Rafael, Cal. Filed Aug. 9, 1905. Serial No. 273,264.



Claim.—1. A thill-coupling, consisting of a shaft-iron having a transverse cylindrical bar, a socket and journal for the bar, said socket consisting of a fixed segment carrying one member of the box, a swinging link carrying the other member of the box and closable with relation to the segment, a plate having one end hinged and the opposite end pivotally connected to the link, and a spring operating the plate intermediate of end connections.

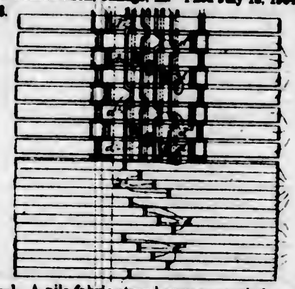
2. In a thill-coupling the combination of coacting members between which the thill-iron is received one of said members opening and closing relative to the other, and having an extended arm portion, a plate hinged at one end and extending to the arm of said movable member and hingedly connected therewith, and a spring acting upon said plate intermediate of its said ends whereby said movable member is held in a closed position.

3. In a thill-coupling, bars secured to the vehicle-axle and having segmental wear-pieces fitted to the front ends to receive the thill-irons, arms swiveled below the bars and carrying the opposing members of the wear-pieces, plates hinged at one end to a fixed point and extending to the arms and hingedly connected therewith, and a spring engaging the plate at an intermediate point and operating in a vertical plane to hold the said opposing member of the arms in a closed position relative to the companion member acting to hold said wear-pieces in position to clasp the thill-irons.

4. In a thill-coupling, bars secured to the vehicle and segmental wear-pieces carried by the front ends of the bars, arms carrying opposing wear-pieces, said arms extending downwardly, hinged plates to which the arms are pivoted and springs fixed between the plates and the bars.

5. In a thill-coupling, bars fixed to the vehicle-axle with segmental wear-pieces at the front ends, arms carrying opposing wear-pieces and extending down below the bars, plates to which the arms are pivoted, said plates being hinged to the bars, and springs interposed between the bars and plates.

810,553. WOVEN PILE-FABRIC ROPE. AUGUST R. NEUF and CARL G. BOLDENWECK, Chicago, Ill. Filed July 18, 1904. Serial No. 217,016.



Claim.—1. A pile-fabric strand or rope consisting of a middle ply and two outer plies, the middle ply consisting of weft-strands and two separated sets of warp-strands interwoven therewith, and the outer plies consisting of weft-strands and a set of warp-threads interwoven with the weft-strands of the middle ply between the warp-threads of the latter, and with said weft-strands of the outer ply.

2. A pile-fabric strand or rope consisting of a middle ply and two outer plies, the middle ply consisting of weft-strands and warp-strands interwoven therewith, and the outer plies consisting of weft-strands and warp-threads interwoven with the weft-strands of the middle ply, and with said weft-strands of the outer ply, each of said weft-strands of the outer plies being engaged at a point between its ends by a single loop only of one of the warp-threads.

3. A pile-fabric strand or rope consisting of a middle ply and two outer plies, the middle ply consisting of weft-strands and warp-threads interwoven therewith, and the outer plies consisting of weft-strands and warp-threads interwoven with the weft-strands of the middle ply, and with said weft-strands of the outer plies, each of said weft-strands of the outer plies being engaged by a single loop only of one of the warp-strands and the loops of said warp-threads which engage said weft-strands of the outer plies being arranged obliquely in uniformly-spaced groups.

810,554. POLISHING-MACHINE. JOHN NELSON, Peru, Ill., assignor of one-third to Walter H. Mann and one-third to Rudolph F. Struever, Peru, Ill. Filed Apr. 17, 1905. Serial No. 256,236.

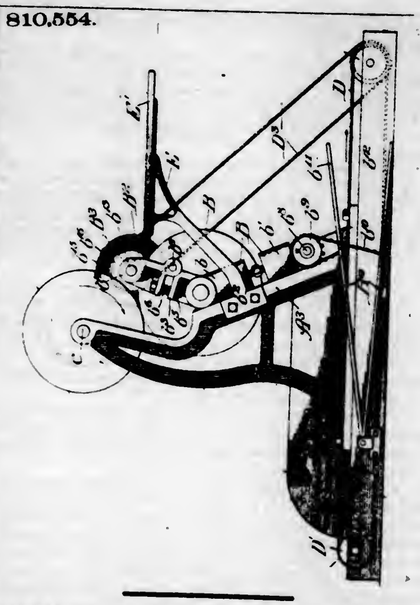
Claim.—1. In a metal-polishing machine, the combination of a frame, a buffing-cylinder journaled thereon, a sheet-supporting cylinder and a feed-roll located beneath and coacting therewith, and means for moving said sheet-supporting cylinder and feed-roll away from the buffing-cylinder, for the purpose set forth.

2. In a machine of the character set forth, the combination of a frame, a polishing-cylinder supported thereon, a slide connected with said frame, a sheet-supporting cylinder connected with said slide, and a coacting feed-roll adjustably connected with said slide, for the purpose set forth.

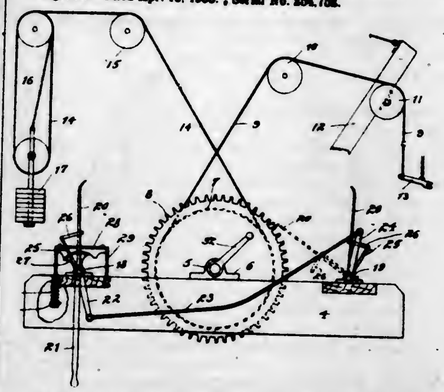
3. In a machine of the character set forth, the combination of a frame, a polishing-cylinder journaled thereon, slides connected with said frame, adjusting means for said slides, a sheet-supporting cylinder journaled in said slides beneath the polishing-cylinder, frame members pivotally and adjustably connected with said slides, and a feed-roll journaled in said frame members, for the purpose set forth.

4. In a machine of the character set forth, the combination of a frame, a buffing-cylinder, guides on said frame, slides of adjustable length connected with said guides, eccentrics supporting said slides, a sheet-supporting cylinder journaled in said slides, members pivotally connected with said slides, adjusting-screws connecting said members with said slides, and a feed-roll journaled in the pivoted adjustable members, for the purpose set forth.

810,554.



810,555. TRIPPING APPARATUS. WILLIAM J. NEWMAN, Chicago, Ill. Filed Apr. 10, 1905. Serial No. 254,782.



Claim.—1. In a tripping apparatus of the character set forth, the combination of a drum, a trip-line adapted to be wound on said drum, means for revolving said drum to take up slack in said trip-line, and means for positively and unyieldingly stopping said drum to cause the trip-line to actuate the tripping device.

2. In a tripping apparatus of the character set forth, the combination of a drum, a trip-line adapted to be wound around said drum in one direction, a take-up line adapted to be wound around the drum in the direction opposite to said trip-line, means for giving a tension to said take-up line, and means for positively and unyieldingly locking said drum to prevent its revolving in either direction.

3. In a tripping apparatus, the combination of a drum, a trip-line adapted to be wound around said drum in one direction, a take-up line adapted to be wound around said drum in the opposite direction, said take-up line being wound through suitable blocks, a weight connected with one of said blocks to give said take-up line sufficient tension to take up the slack in the trip-line, a toothed wheel mounted with said drum and pawls adapted to be thrown into engagement with said toothed wheel.

4. The combination of a drum, a trip-line, a tension-line, means for producing tension in the latter line, a toothed wheel mounted with said drum, pawls on either side of said toothed wheel, and

means for throwing said pawls simultaneously into and out of engage-

bears against the adjacent groove-wall when the

means for throwing said pawls simultaneously into and out of engagement with said wheel.

5. The combination with a drum for a trip-line, of a toothed wheel mounted with said drum and adapted to rotate therewith, pawls adapted to engage with said toothed wheel, shafts on which said pawls are mounted, means for turning one of said shafts, and means connecting between said shafts whereby they will be turned simultaneously.

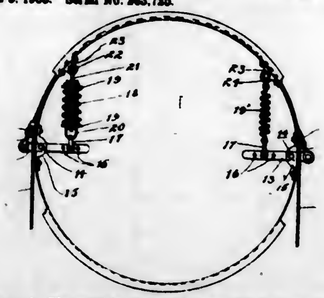
6. The combination of a trip-line drum, a shaft on which said drum is mounted, a ratchet-wheel on said shaft, pawl-shafts mounted adjacent to said drum-shaft, means for turning one of said pawl-shafts, means for causing the other shaft to be turned simultaneously with the first-named shaft, pawls loosely mounted on said shafts and actuating-levers on said shafts adapted to throw said pawls into and out of engagement with the ratchet-wheel.

7. The combination of a ratchet-wheel, a shaft adjacent to said ratchet-wheel, a pawl loosely mounted on said shaft and adapted to engage with said ratchet-wheel, an actuating-lever on said shaft for throwing said pawl into and out of engagement, the arrangement being such that the actuating-lever will have a certain amount of play before throwing the pawl, and means for turning the shaft on which said pawl and actuating-lever are secured.

8. The combination of a ratchet-wheel, a shaft adjacent to said ratchet-wheel, a pawl on said shaft adapted to engage with said ratchet-wheel, means for manually turning said shaft and a brake for holding said shaft in adjusted position.

9. The combination of a trip-line drum, a shaft on which said drum is mounted, a crank for turning said shaft, a toothed wheel on said shaft, pawl-shafts mounted adjacent to said drum-shaft and substantially parallel therewith, pawls loosely mounted on said shafts, actuating-levers secured to said shafts for throwing said pawls, arms extending from said shafts in opposite directions, a rod connecting between the ends of said arms, a handle for turning one of said shafts, and an adjustable brake on one of said shafts.

810,556. DERRICK. WILLIAM J. NEWMAN, Chicago, Ill. Filed June 5, 1905. Serial No. 263,725.



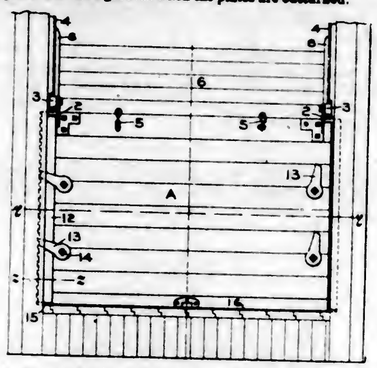
Claim.—1. The combination with a derrick bull-wheel, of a lever pivoted to said wheel, an operating-cable connected to one end of said lever, and a spring connected to the opposite end of said lever and to said wheel.

2. The combination with a bull-wheel for a derrick, of a lever pivoted to said wheel with one end extending out therefrom, an operating-cable connected with said outer end, a compression-spring connected with the inner end of said lever and with said wheel, the arrangement being such that the tension of the spring is opposed to the pull on said cable.

3. In a derrick, the combination of a bull-wheel or the like, a bearing adjacent to the periphery of said wheel, a lever pivoted to said bearing and extending out from said wheel, an operating-cable connected to the outer end of said lever and engaging with the outer periphery of said wheel, rods or the like adjustably connected with the inner end of said lever, a second rod connected to a bearing on the inner periphery of said wheel, and a compression-spring adapted to coact with said rods to oppose the pull on said cable.

810,557. SLIDING HINGED GRAIN-DOOR. KNUTE OSSE, St. Paul, Minn. Filed Sept. 23, 1905. Serial No. 279,706.

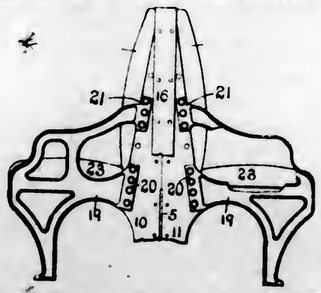
Claim.—1. The combination with a car formed with a door-frame and a slidably-hinged door of less width than the door-opening, a pair of right-angled plates secured in right-angled grooves in the inner corners of the door-frame whereby one wall of each plate bears against the adjacent groove-wall when the plates are outturned, and catches carried by said door in position to be turned over said plates into said grooves when the plates are outturned.



2. The combination with a car formed with a door-frame, and a slidably-supported hinged door of less width than the door-opening, a threshold having openings in its ends, right-angled plates having slidable hinge-support in grooves in the inner faces of the sides of the door-frame in position to drop into openings in the ends of said threshold, and to rest upon said threshold when outturned, and catches pivotally supported upon the outer face of the door in position to be turned over said plates into said grooves when said plates are outturned.

3. The combination with the car formed with a door-frame, a hinged door of less width than the door-opening, the threshold having openings in its ends, a pair of right-angled plates having slidable hinge-support in grooves in the inner faces of the sides of the door-frame in position to drop into said openings in the threshold when turned against the door-frame, flanges carried by the lower ends of said plates to rest upon said threshold when said plates are outturned, and catches pivotally supported upon the outer face of said door in position to be turned over the outturned plates in said grooves.

810,558. CAR-SEAT. ALLEN H. OSTRANDER, Paterson, N. J., assignor to American Car & Foundry Company, St. Louis, Mo., a Corporation of New Jersey. Filed July 26, 1905. Serial No. 271,342.



Claim.—1. In a car-seat, the combination with the cross-bearers of the underframing and the sides of a car, of a gusset secured to the side of the car and extending down alongside of the cross-bearer, fastening devices extending through said gusset and cross-bearer, a standard fastened to one end of the gusset, a seat-cushion support connected to said standard, a back-cushion support connected to said standard and to said seat-cushion support, and a connection between said seat-cushion support and the side of the car; substantially as described.

2. The combination with the underframing of a car and the car side, of braces connected to the car side and extending below the floor, connecting devices extending through the underframing and the braces below the floor of the car, a standard connected to one of the braces distant from the side of the car, a connection between the upper portion of the standard and the car side, a seat-cushion support secured to the standard, and a connection between the seat-cushion support and the side of the car; substantially as described.

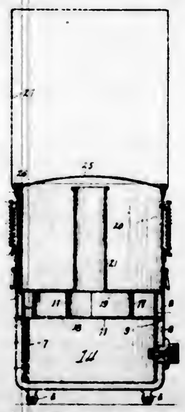
3. In a car, the combination with channel cross-bearers and plate-girder sides, of a gusset riveted to the plate-girder sides and extending down beside one of the cross-bearers, connecting devices extending through said cross-bearer and gusset below the floor of the car, a standard carried by said gusset and distant from the side, means for supporting a seat-cushion and connected to said standard, and connections between the standard and seat-cushion support and the plate-girder side; substantially as described.

4. In a railway-car, the combination with channel cross-bearers extending from side sill to side sill, posts carried by the side sill and cross-bearers, a gusset riveted to the posts and extending down alongside of one of the cross-bearers, fastening devices extending through said gusset and cross-bearer below the floor of the car, a standard connected to the gusset, and means connected to the standard and car side for supporting a seat portion and back portion of the car-seat; substantially as described.

5. In a railway-car, the combination with a cross-bearer and upstanding posts, a gusset connected to one of the upstanding posts and an adjacent cross-bearer, a standard comprising a plurality of parts 10 and 11 provided with parallel flanges, means for securing one edge of the gusset between said flanges, and connections between said standard and the car side; substantially as described.

6. In a railway-car, the combination with cross-bearers and vertical posts, gussets secured to the sides of the car and extending below the floor of the car, connecting devices extending through said gussets and adjacent cross-bearers below the floor of the car, a standard secured to one edge of one of the gussets and having upwardly-converging flanges, oppositely-disposed seat-cushion supports connected to said standard, connections between the converging flanges of the standard and the side of the car, and connections between the seat-cushion supports and the side of the car; substantially as described.

810,559. DUST-COLLECTOR. JOHN V. O. PALM, Milwaukee, Wis., assignor to The American Compressed Air Supplying Company, Milwaukee, Wis., a Corporation of Wisconsin. Filed May 17, 1905. Serial No. 260,790.



Claim.—1. In a dust-collector, an expansion-chamber in which dust-laden air under pressure may partially expand, a baffle-drum into which the air passes from the expansion-chamber, a spirally-arranged baffle-plate in the baffle-drum forming a spirally-curved passage-way of gradually-increasing size, and a strainer into which the passage-way discharges.

2. In a dust-collector, an expansion-chamber in which dust-laden air under pressure may partially expand, a baffle-drum receiving the air from the expansion-chamber, a removable bucket having a spout attached to the bottom thereof receiving the air from the baffle-drum, and a strainer connected with the bucket and adapted to deposit dust in the bucket.

3. In a dust-collector, a casing, a baffle-drum fitting therein and forming an expansion-chamber in the casing in which dust-laden air under pressure may partially expand, said baffle-drum being adapted to receive the air from the expansion-chamber, a spirally-arranged baffle-plate in the baffle-drum forming a spirally-curved passage-way increasing in size for the passage of air therethrough, a bucket fitting against the baffle-drum and closing the passage-way of the drum, a spout extending from the bottom of the bucket, adapted to receive the air from the passage-way, and a strainer connected with the bucket.

4. In a dust-collector, a casing, a shouldered lining in the casing constituting an expansion-chamber in which dust-laden air may partially expand and with the casing forming a sound-deadening jacket around the expansion-chamber, a baffle-drum seated on the shoulder of the lining receiving the air from the expansion-chamber, and a strainer into which the baffle-drum discharges.

5. In a dust-collector, a casing, a shouldered lining therefor forming an expansion-chamber in which dust-laden air under pressure may partially expand surrounded by a sound-deadening jacket, a gasket on the shoulder of the lining, a baffle-drum seated on the gasket and receiving the air from the expansion-chamber, a sound-deadening jacket for the baffle-drum, and a strainer into which the baffle-drum discharges.

6. In a dust-collector, a casing, a shouldered lining therein forming a jacketed expansion-chamber in which dust-laden air under pressure may partially expand, a baffle-drum seated on the shoulder of the lining and receiving the air from the expansion-chamber, a spirally-arranged baffle-plate in the baffle-drum forming a spirally-curved passage-way gradually increasing in size for the passage of the air, a gasket fitting on the baffle-drum and closing the passage-way except at the enlarged middle portion thereof where the gasket is provided with an opening through which the air may pass, a bucket fitting in the casing and seated on the gasket, an upwardly-extending spout passing through the bottom of the bucket and registering with the opening of the gasket, and a strainer connected with the bucket.

7. In a dust-collector, a casing having a shoulder, a baffle-drum seated on the shoulder and forming an expansion-chamber with the casing in which dust-laden air under pressure may partially expand, said baffle-drum having an opening therethrough to receive air from the expansion-chamber, a spirally-arranged baffle-plate in the baffle-drum forming a spirally-curved passage-way gradually increasing in size leading from the opening through the bottom of the baffle-drum to the middle portion thereof, a gasket seated on the baffle-drum and closing the passage-way thereof except at the middle portion where the gasket is provided with an opening through which the air may pass, a bucket fitting in the casing and seated on the gasket, a spout passing through the bottom of the bucket and registering with the opening of the gasket, a strainer on the bucket, and means for holding the bucket against the casing.

8. In a dust-collector, a casing having a shoulder, a baffle-drum seated on the shoulder and forming an expansion-chamber with the casing in which dust-laden air under pressure may partially expand, said baffle-drum having an opening therethrough to receive air from the expansion-chamber, a spirally-arranged baffle-plate in the baffle-drum forming a spirally-curved passage-way gradually increasing in size leading from the opening through the bottom of the baffle-drum to the middle portion thereof, a gasket on the baffle-drum and closing the passage-way thereof except at the middle portion where the gasket is provided with an opening through which the air may pass, a bucket fitting in the casing and seated on the gasket, a spout passing through the bottom of the bucket and registering with the opening of the gasket, a strainer on the bucket, and springs connecting the bucket with the casing to tightly clamp the gasket between the bucket and the baffle-drum.

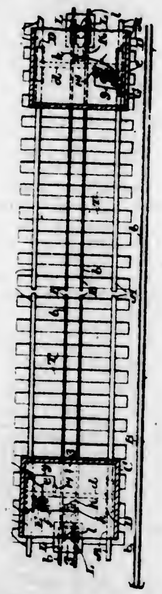
9. In a dust-collector, a casing, a shouldered lining therein forming an expansion-chamber surrounded by a sound-deadening jacket, a filling of sound-deadening material in the space between the lining and the casing, a coupling passing through the wall of the expansion-chamber and adapted to discharge dust-laden air under pressure into said expansion-chamber, a gasket on the shoulder of the lining, a baffle-drum seated on the gasket and having an opening through its bottom to receive air from the expansion-chamber, a sound-deadening jacket surrounding the baffle-drum, sound-deadening material in said sound-deadening jacket, a spirally-arranged baffle-plate in the baffle-drum forming a spirally-curved passage-way gradually increasing in size for the passage of air therethrough from the opening in the bottom of the baffle-drum to the center thereof, a gasket fitting on the baffle-drum and baffle-plate and closing the passage-way except at its middle portion where it is provided with an opening through which the air may pass, a bucket fitting in the casing and seated on the last-named gasket, a spout passing through the bottom of the bucket and registering with the opening of the gasket to receive the air from the passage-way, springs connecting the bucket with the casing, a handle on the bucket, and a bead on the mouth of the bucket with which the mouth of a strainer-bag may be connected.

10. In a dust-collector, a bucket adapted to have a strainer-bag

connected to its mouth, and a spout leading from an opening in the bottom of the bucket to admit dust-laden air thereto, said spout serving to prevent the incoming air from disturbing the dust previously collected in the bucket and also preventing the dust falling out of the bucket through the opening in the bottom thereof when the bucket is being moved from place to place.

11. In a dust-collector, a baffle-drum, a baffle-plate therein forming a passage-way gradually increasing in size, a removable cover for the baffle-drum closing the passage-way, means for supplying the passage-way with dust-laden air under pressure which may expand in the enlarging passage-way, a strainer having communication with the passage-way at its largest part, and a sound-deadening jacket surrounding the baffle-drum.

810,560. ELECTRIC RAILWAY-SIGNAL. HELEN W. PARKES and STELLA L. VINCENT, Cleveland, Ohio. Filed Oct. 17, 1904. Serial No. 228,808.

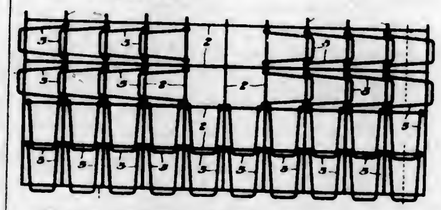


Claim.—1. The combination, with a railway-track comprising two parallel rails, and vehicles mounted and movable on the said track, of a trolley-track arranged between and parallel with and extending longitudinally of the railway-track and composed of conductor-forming rail-sections, with adjacent rail-sections of the trolley-track electrically insulated from each other and from the rails of the railway-track; a trolley-wheel borne by each vehicle and engaging the trolley-track; means whereby an alarm is automatically operated on each of two vehicles when the trolley-wheels of both vehicles make contact with one and the same rail-section of the trolley-track, and a suitably-supported rotary brush adjacent each trolley-wheel and arranged opposite and in close proximity to the periphery of the said wheel.

2. In combination, with a railway-track comprising two parallel rails; vehicles mounted and movable on the said track; a trolley-track consisting of two rails arranged between and parallel with and extending longitudinally of the rails of the railway-track, with each rail of the trolley-track composed of conductor-forming rail-sections arranged end to end and electrically insulated from each other and from the rail-sections of the other rail of the trolley-track and alternating with the last-mentioned rail-sections, and each of the aforesaid vehicles being provided with the following: two conductor-forming trolleys engaging the different rails respectively of the trolley-track, a conductor-forming trolley-frame bearing and extending between and electrically connected with the said wheels; brushes supported from the said frame and arranged in close proximity to the peripheries of the wheels; a hood supported from the trolley-frame and extending over the brushes and trolley-wheels; an electric source; an electric alarm; an electric connection between one of the terminals of the alarm and one of the terminals of the electric source, and the other terminal of the electric source and the other terminal of the alarm being electrically connected the one with the trolley-frame and the other with a rail of the railway-track.

3. In combination, with a railway-track comprising two parallel rails; vehicles mounted and movable on the said track; a trolley-track consisting of two rails arranged between and parallel with and extending longitudinally of the rails of the railway-track, with each rail of the trolley-track composed of conductor-forming rail-sections arranged end to end and electrically insulated from the rails of the railway-track, with adjacent rail-sections of each rail of the trolley-track electrically insulated from each other and from the rail-sections of the other rail of the trolley-track and alternating with the last-mentioned rail-sections, and each of the aforesaid vehicles being provided with the following: two conductor-forming trolleys engaging the different rails respectively of the trolley-track, a conductor-forming trolley-frame bearing and extending between and electrically connected with the said wheels; brushes supported from the said frame above the wheels and arranged in close proximity to the peripheries of the wheels; a hood supported from the trolley-frame and extending over the brushes and trolley-wheels; an electric source; an electric alarm; an electric connection between one of the terminals of the alarm and one of the terminals of the electric source, and the other terminal of the electric source and the other terminal of the alarm being electrically connected the one with the trolley-frame and the other with a rail of the railway-track.

810,561. REINFORCING DEVICE FOR CONCRETE CONSTRUCTION. GEORGE L. PEABODY, Pittsburg, Pa. Filed Oct. 21, 1904. Serial No. 229,361.



Claim.—1. A reinforcing device for concrete, &c., consisting of a flat web-like base having main and cross strands, and holding-arms connected therewith by winding their extremities around the strands of the base, substantially as set forth.

2. A reinforcing device for concrete, &c., consisting of a flat web-like base having main and cross strands, and looped holding-arms attached thereto and adapted to be set at varying angles, substantially as set forth.

3. A reinforcing device for concrete, &c., consisting of a flat web-like base having main and cross strands, and holding-arms attached thereto arranged to be bent in oppositely-disposed upwardly and outwardly slanting directions, substantially as set forth.

4. A reinforcing device for concrete, &c., consisting of a flat web-like base having main and cross strands, and looped holding-arms attached to the main and cross strands and adapted to be bent in relatively cross planes and at varying angles to the base, substantially as set forth.

5. A reinforcing device for concrete, &c., consisting of a flat web-like base having main and cross strands, and holding-arms having their extremities secured to the main and cross strands and adapted to be bent in relatively cross planes and at various angles to the base, substantially as set forth.

810,562. GAS-REGULATOR. BENJAMIN H. PEYLEY, Seattle, Wash. Filed Feb. 23, 1905. Serial No. 246,818.

Claim.—1. In a device of the character described, the combination with a two-part casing, a valve controlling a port in the casing, a stem and a float, of means provided on the stem for limiting the closing movement of the valve, and means for effecting the adjustment of the casing parts for varying the relative position of the said valve to the port which it controls whereby the amount of valve-port opening may be regulated.

2. In a device of the character described, the combination with the casing provided with inlet and outlet gas-openings, a valve-seat and an annular chamber for containing a liquid seal and a removable cover for said casing, of an inverted-cup-shaped member having its depending wall projecting into said chamber, an elongated tapering valve connected to said member, said valve being of less area at its largest part than the area of said valve-seat, whereby a capacity will be afforded around the valve at all positions of the same, and means to adjust the position of the said valve from the exterior of the casing without detaching said cover therefrom.

3. In a device of the character described, the combination with the casing provided with gas inlet and outlet openings, and partitions extending across the casing above and below the said outlet-opening and severally provided with axially-disposed apertures, of a valve of less cross-sectional area throughout than the aperture of said lower partition said valve passing through said lower partition and having a stem extending up through the aperture and carrying a float thereabove, and means provided on said stem below the level of the upper partition for limiting the upward movement of said valve.

4. In a device of the character described, the combination with the casing provided with inlet and outlet openings and having a valve-port therebetween, a tapering valve of less diameter than the said port and positioned therein, said valve being provided with a plurality of flat inwardly-sloping faces whereby the area of the port-opening is increased through descending movement of the valve, a stem for said valve, and a float carried upon said stem.

5. In a device of the character described, a two-part casing, means for adjustably connecting them together, a valve located within the casing and means whereby the adjustment of the parts of the casing will effect the adjustment of said valve.

6. In a device of the character described, the combination with a casing part provided with gas inlet and outlet openings and having a valve-port therebetween, another casing part having an annular seal-chamber therein and adjustably connected to the first-named part, a cylindrical valve of less diameter than the said valve-port and extending therethrough said valve being formed so that the port area thereabout is increased correspondingly with its downward movement and diminished during its ascending movement but at no time closing the said port, a stem projecting up through the second-named casing part, a float secured to said stem having a depending circular wall projecting interiorly of said annular chamber, means provided intermediate the float and valve for limiting the upward movement thereof, and a removable weight for the said stem exteriorly of the casing.

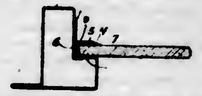
810,563. GAS-PURIFYING APPARATUS. PIERRE PLANTINGA, Cleveland, Ohio. Filed June 28, 1905. Serial No. 267,249.

Claim.—1. In a device for extracting tar from gaseous mixtures, a series of plates interposed in the path of the gas, said series consisting of alternately-arranged perforated plates constructed to divide the gas into a multiplicity of streams, and baffle-plates having openings and constructed to receive the impact of the gaseous masses constituting such streams, each dividing-plate being arranged to offer less resistance to the passage of gas therethrough than does the next succeeding dividing-plate.

2. In a device for extracting tar from gaseous mixtures, a series of plates interposed in the path of the gas, said series consisting of alternately-arranged perforated plates constructed to divide the gas into a multiplicity of streams, and baffle-plates having openings and constructed to receive the impact of the gaseous masses constituting such streams, the area of the perforations of each dividing-plate being markedly greater than the area of the perforations of the next succeeding dividing-plate.

810,564. FIREPROOF WINDOW. SILAS H. POMEROY, New York, N. Y., assignor of one-half to Frank Voigtmann, Chicago, Ill. Filed May 8, 1905. Serial No. 259,269.

Claim.—1. A window or analogous sash provided with a glazing-retaining strip having a series of sight-openings formed therethrough and adapted to overlie the edge of the glazing to confine the latter.

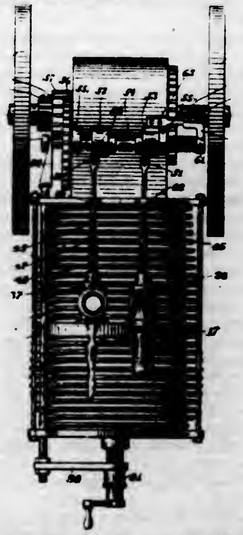


2. A window or analogous sash provided with a substantially continuous glazing-retaining strip extending around the interior of the sash-frame, having sight-openings formed therethrough at intervals apart.

3. A window or analogous sash provided with an adjustable glazing-retaining strip having a series of sight-openings formed therethrough, and means for locking said retaining-strip to the sash-frame.

4. In combination, a window or analogous sash-frame of hollow sheet-metal construction and provided with an internal shoulder forming a seat to receive the margins of the glazing, a glazing, a retaining-strip angular in cross-section and arranged with one of its angles interposed between the edge of the glazing and the opposed inner surface of the sash-frame, and a series of nibs formed integrally with the sash-frame and bent to overlie the retaining-strip, said retaining-strip being provided with a series of sight-openings at intervals throughout its length.

810,565. GAS-ENGINE. EDWIN F. PORTER and WALTER R. WHITING, Boston, Mass., assignors to American Rotary Engine Company, Boston, Mass., a Corporation of Maine. Filed Nov. 24, 1900. Renewed Mar. 16, 1905. Serial No. 250,406.



Claim.—1. An engine comprising a piston and cylinder, a pair of crank-shafts mounted parallel with each other, a pair of connecting-rods extending from said piston to said shafts, a gear mounted on each shaft and intermeshing one with the other, and a fly-wheel keyed to one end of each crank-shaft and located on opposite sides of the engine.

2. An engine comprising a piston and cylinder, a pair of crank-shafts mounted parallel with each other, a pair of connecting-rods extending from said piston to said shafts, a gear mounted on each shaft and intermeshing one with the other, a weight carried by each shaft, and a fly-wheel keyed to one end of each crank-shaft and located on opposite sides of the engine.

3. An engine comprising a piston and cylinder, a pair of crank-shafts mounted parallel with each other, a pair of connecting-rods extending from said piston to said shafts, fly-wheels mounted on each shaft and means for automatically preventing reverse rotation of said fly-wheels.

4. An engine comprising a piston and cylinder, a pair of crank-shafts mounted parallel with each other, a pair of connecting-rods extending from said piston to said shafts, fly-wheels mounted on each shaft, and means normally in engagement with the periphery of each fly-wheel adapted to automatically prevent reverse rotation thereof.

5. A gas-engine comprising a piston and cylinder having means whereby all the explosive mixture is drawn into the cylinder by the piston, an abutment located in said cylinder, a threaded pin arranged to vary the position of said abutment whereby the operative volume is correspondingly varied, a threaded collar working on said threaded pin, and means operated by said collar for automatically varying the amount of explosive mixture compressed within said cylinder.

6. A gas-engine comprising a piston and cylinder having means whereby all the explosive mixture is drawn into the cylinder by the piston, an abutment located within said cylinder a pin serving as a guide for said abutment, means for adjusting said pin, whereby the position of said abutment is varied, and means automatically operated by said pin for varying the amount of explosive mixture compressed within said cylinder.

7. A gas-engine comprising a piston and cylinder having means whereby all the explosive mixture is drawn into the cylinder by the piston, a cushioned abutment located within said cylinder and means for simultaneously varying the relative position of said abutment and varying the amount of explosive mixture compressed within said cylinder.

8. A gas-engine comprising a piston and cylinder having means whereby all the explosive mixture is drawn into the cylinder by the piston, an abutment located in said cylinder, a threaded pin arranged to vary the position of said abutment whereby the operative volume is correspondingly varied, valve mechanism for admitting explosive mixture to said cylinder, means for operating the same, a threaded collar working on said threaded pin and means operated by said collar for varying the relation between said valve mechanism and its operating means.

9. A gas-engine having a piston and cylinder, means for varying the operative volume in said cylinder, and mechanism automatically controlled by said means, whereby said piston is permitted to draw the explosive mixture into the cylinder and automatically expel a predetermined portion thereof, said mechanism also permitting the entrance of the expelled mixture to the cylinder at the next cycle of operation of the engine.

10. A gas-engine comprising a piston and cylinder, means for varying the operative volume within said cylinder, an inlet-valve, means for operating the same, means automatically controlled by said volume-varying means for controlling said valve, operating means whereby the piston is permitted to draw the explosive mixture into the cylinder and expel a predetermined portion thereof past said inlet-valve and means for receiving said expelled explosive.

11. A gas-engine comprising a cylinder and piston, an abutment located in said cylinder, a threaded rod for varying the position of said abutment, a collar working on said rod, and mechanism automatically controlled by the movement of said collar, whereby a part of the explosive mixture is permitted to escape from said cylinder.

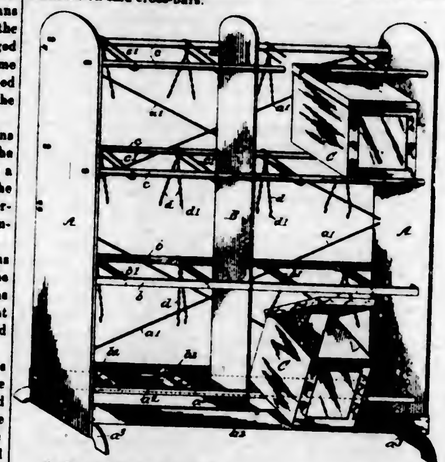
12. A gas-engine comprising a cylinder and piston, an abutment located in said cylinder, a threaded rod for varying the position of said abutment, a collar working on said rod, an inlet-valve, mechanism for operating the same having means for controlling the movement of said valve whereby a part of the explosive mixture is expelled from said cylinder, and connections between said collar and said valve mechanism, whereby the valve-controlling means is automatically operated.

13. A gas-engine comprising a piston and cylinder, an adjustable abutment located in the latter, an inlet-pipe having a check-valve, an inlet-valve intermediate of said check-valve and said cylinder, valve-operating mechanism for said check-valve arranged to permit the piston to draw the explosive mixture into the cylinder and to expel a part thereof into said inlet-pipe past said inlet-valve, and a gas-bag intermediate of said inlet and check valves adapted to receive the expelled gas whereby the latter is introduced into the cylinder for the next succeeding explosion.

14. A gas-engine having a piston and cylinder, an abutment located in the latter, a threaded rod for adjusting the same, an inlet-valve, differential valve-operating mechanism, a threaded collar working on said rod, and connections between said collar and said valve-operating mechanism.

810,566. RACK FOR CRACKER-CANS. EVAN L. REES, Oregon, Ill. Filed Aug. 2, 1905. Serial No. 272,909.

Claim.—1. In a knockdown rack for cracker-cans, end uprights, longitudinal bars detachably secured to said uprights in pairs and connecting the uprights together, said bars forming supports for cracker-cans, cross-bars connecting said longitudinal bars together, and means for detachably holding can-covers, said means slidably mounted on said cross-bars.



2. In a knockdown rack for cracker-cans, end uprights, longitudinal bars detachably secured to said uprights in pairs and connecting theuprights together, said bars forming supports for cracker-cans, cross-bars connecting said longitudinal bars and arranged to lie over the center of the cans and having a slideway therein, flexible means for holding the can-covers, said means slidably arranged on said cross-bars and adapted to be detachably connected with the can-covers.

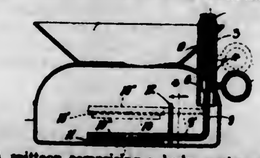
3. In a knockdown rack for cracker-cans or the like, end uprights, parallel longitudinal bars detachably secured to the uprights and forming supports for cracker-cans, cross-bars connecting the longitudinal bars together and forming supports for said cans, chains slidably arranged on said cross-bars, said chains having means secured to their ends for detachably holding cans arranged on said longitudinal and cross bars.

4. In a knockdown rack for cracker-cans, end uprights, longitudinal can-supporting bars detachably secured to said uprights, and can-supporting cross-bars connecting said longitudinal bars together, having a slideway therein and arranged to lie over the center of the cans, and means arranged in said slideway for holding the can-covers.

5. In a knockdown rack for cracker-cans, end uprights, parallel can-supporting longitudinal bars detachably secured to said uprights, cross-bars connecting said longitudinal bars together, a middle detachable upright connected with the longitudinal bars, diagonal braces detachably secured to the rear portion of the uprights and so arranged as to limit the rearward movement of the cans.

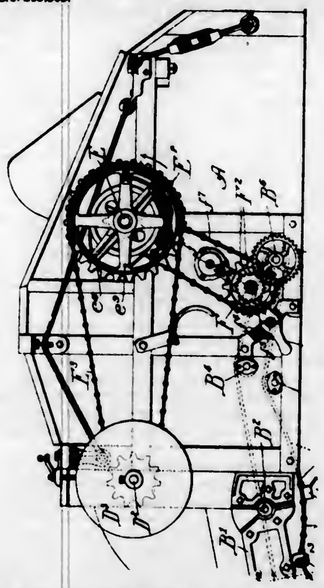
6. In a knockdown rack for cracker-cans, end uprights, can-supporting longitudinal bars detachably secured to said uprights, means for drawing together the uprights and bars to form a rigid structure, cross-bars detachably connected with the longitudinal bars, and can-holding devices detachably and slidably connected with said cross-bars and adapted to be detachably connected with the covers of the cans.

810,567. SPITTOON. FRANK REHBERGER, St. Louis, Mo., assignor of one-third to Edwin J. Rotzschmidt and one-third to August J. Hoop, St. Louis, Mo. Filed Sept. 26, 1905. Serial No. 280,619.



Claim.—A spittoon comprising a body portion and a flaring mouth, and having a bottom discharge-opening a tube disposed between the wall of said mouth and body portion, a movable head in said tube, an upwardly-projecting stem secured to the head and confined in said tube, a spring encircling the stem and bearing with one end against the head, a finger-loop having a stem operating through the wall of the tube and connected to the head, a rod depending from the head and projecting into the spittoon, and a valve-plug coupled to the rod, and cooperating with the discharge-opening substantially as set forth.

810,568. FEEDING AND BAND-CUTTING MECHANISM. FREDERICK S. REES, Canton, Ohio, assignor to Rich Self Feeder Company, St. Louis, Mo., a Corporation of Missouri. Filed June 20, 1904. Serial No. 213,208.



Claim.—1. The combination with a rotary band-cutter, an endless sheaf-conveyer, and a feed device located above the path of the grain and provided with a driving-shaft, of power-transmission means connecting the band-cutter, feed device and sheaf-conveyer, comprising a friction-clutch connected with said shaft and operated by increase of torsional force upon said shaft, due to an overload of grain, for retarding the conveyer, to permit the restoration of normal conditions, for the purpose set forth.

2. The combination with a rotary band-cutter, an endless sheaf-conveyer, and a feed device located above the path of the grain, of power-transmission means connecting the band-cutter, feed device and sheaf-conveyer, comprising a wheel rotatable with relation to the shaft of said feed device and geared to said band-cutter, a member connected with said shaft through the medium of which the shaft is rotated, spring connection between said wheel and member, a friction-wheel, a friction-strap thereon connected with said first-named wheel and with said shaft-actuating member, and means for communicating motion from said friction-wheel to said conveyer, for the purpose set forth.

3. The combination with a feed device having a crank-shaft, of a suitably-actuated wheel revoluble with relation to said crank-shaft, a friction-wheel adjacent thereto, a member fixed to said crank-shaft, a spring yieldingly maintaining said first-named wheel and said member in a given relation, an endless sheaf-conveyer, and means for transmitting power from said friction-wheel to said conveyer, for the purpose set forth.

4. The combination of an endless sheaf-conveyer, a crank-shaft equipped with oscillating feeding devices located above the rear portion of said conveyer, a wheel revoluble on said crank-shaft, an actuating member fixed to said crank-shaft, spring connection between said wheel and said member, a friction-wheel adjacent to said member, a friction-strap passing about said friction-wheel and connected to said first-named wheel and to said member, means for actuating said first-named wheel, and means for transmitting power from said friction-wheel to said conveyer, for the purpose set forth.

5. The combination of an endless conveyer, a crank-shaft equipped with oscillating feed devices located above the rear end of said conveyer, a rotary band-cutter in advance of said crank-shaft and equipped with a speed-governor, a wheel journaled on said crank-shaft and geared to said speed-governor, yielding connection between said wheel and said crank-shaft, and a friction-clutch serving normally to transmit power from the crank-shaft to the endless conveyer and which is automatically released to retard the conveyer when said feed devices encounter an overload abnormally increasing the torsional resistance at the crank-shaft, for the purpose set forth.

6. In mechanism of the character set forth, the combination with a feed device having a driving-shaft, and a sheaf-conveyer, of means for transmitting power from the feed device to the sheaf-conveyer, comprising a suitably-actuated wheel revoluble with relation to the driving-shaft of the feed device, an actuating member for said driving-shaft yielding connection between said wheel and said member, a friction-wheel journaled on said driving-shaft, a friction-strap having its ends connected with said wheel and said member, respectively, a sprocket-wheel connected with said friction-wheel, and a sprocket-chain through which power is transmitted from said sprocket-wheel to actuate the sheaf-conveyer, for the purpose set forth.

7. In mechanism of the character set forth, the combination with an endless sheaf-conveyer, and a crank-shaft equipped with a plurality of feed devices operating above the rear portion of said conveyer, of a sprocket-wheel revoluble with relation to said crank-shaft, a member fixed to said crank-shaft and located at the inner side of the hub thereof, a friction-wheel located at the inner side of said member, spring connection between said sprocket-wheel and said member, a friction-strap upon said friction-wheel and having its ends connected respectively with said sprocket-wheel and said member, and a wheel fixed to revolve with said friction-wheel and serving to transmit power to the conveyer, for the purpose set forth.

8. The combination of an endless sheaf-conveyer having a driving-shaft equipped with a spur-gear, a stub-shaft equipped with a spur-gear meshing therewith and with a sprocket-wheel for actuating said second-named spur-gear, a crank-shaft equipped with a plurality of feed devices and having journaled thereon a sprocket-wheel geared to said first-named sprocket-wheel and a friction-wheel serving to actuate said second-named sprocket-wheel, an actuating member for said crank-shaft fixed to the crank-shaft, a sprocket-wheel on the crank-shaft adjacent to said member, spring connection between said third-named sprocket-wheel and said member, and a sprocket-chain through the medium of which said third-named sprocket-wheel is actuated, for the purpose set forth.

9. In feeding and band-cutting mechanism, the combination with a rotary band-cutter equipped with a plurality of suitably-spaced knives, of a guard comprising a suitable cross-bar and shoes depending therefrom between the knives, each shoe comprising a member provided with oblique flanges and an expanding member confined between said flanges and adjustable with relation thereto, for the purpose set forth.

810,569. CANOPY-FRAME FOR CASKETS. CHARLES H. RICHARDS, Chicago, Ill. Filed May 22, 1905. Serial No. 261,627.

Claim.—1. A canopy-frame for caskets comprising a front bar and two hinge-jointed side arms, said side arms being extensible in length.

2. A canopy-frame for caskets comprising hinge-jointed side arms, means for securing one end of each of said arms to a casket-cover, brackets pivotally connected with the outer ends of said side arms, and a front bar secured to said brackets.

3. A canopy-frame for caskets comprising side arms and a front

bar, each of said side arms comprising two hinge-jointed sections, and each section comprising two members, one of said members being concave or grooved on one of its sides, and the other member lying in said groove and adjustably secured to and longitudinally movable along said other member.

4. A canopy-frame for caskets comprising two side arms, brackets pivotally connected with said side arms, and a front bar connected with said brackets, each of said brackets being adapted to engage said front bar at opposite sides of said bar.

810,570. MACHINE FOR MOLDING GLASS. CHARLES W. RAGEN, Philadelphia, Pa., assignor to Hero Fruit Jar Company, Philadelphia, Pa., a Corporation of Pennsylvania. Filed July 22, 1905. Serial No. 270,873.

Claim.—1. In a glass-molding machine, the combination with a rotary table of a mold carried by the table, said mold having a center movable below its pressing position.

2. In a glass-molding machine, the combination, with a rotary table, of a mold carried by the table, said mold having a center movable below its pressing position, and means in one portion of the revolution of the table whereby said center moves below its pressing position.

3. In a glass-molding machine, the combination with a rotary table, of a mold carried by the table, said mold having a center movable below the pressing position, means in one portion of the revolution of the table whereby said center moves below its pressing position and means in the revolution of the table to return said center to its pressing position.

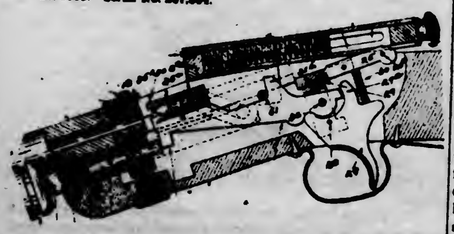
4. In a glass-molding machine, the combination with a rotary table and a fixed plate beneath the same, of a mold carried by the table, said mold having a center movable below its pressing position, there being a portion of said plate in line of movement of said center in the rotation of the table, cut away whereby the center moves below its pressing position.

5. In a glass-molding machine, the combination with a rotary table, and a fixed plate beneath the same, of a mold carried by the table, said mold having a center movable below its pressing position, there being a portion of said plate, in line of movement of said center, in the rotation of the table, cut away whereby the center moves below its pressing position, the ends of said cut-away portion inclining to the level of the surface of the plate.

6. In a glass-molding machine, the combination with a rotary table, of a mold carried by the table, said mold having a center movable below its pressing position, and means, in one portion of the revolution of the table, whereby said center-piece moves below its pressing position, and means to limit the movement of the center.

7. In a glass-molding machine, the combination with a rotary table, of a mold carried by the table, said mold having a center movable below its pressing position, means, in one portion of the revolution of the table, whereby said center-piece moves below its pressing position, means in the revolution of the table to return said center to its pressing position, and means to limit the movement of the center in either direction.

810,571. FIREARM. ARTHUR J. SAVAGE, Utica, N. Y., assignor to J. Stevens Arms & Tool Company, Chicopee Falls, Mass. Filed June 30, 1905. Serial No. 267,994.



Claim.—1. The combination in a firearm of a frame, a breech-bolt slidingly mounted with reference to the frame, and a firing-pin engaging the breech-bolt and slidably connected with the frame and serving as a support and guide for the breech-bolt, substantially as set forth.

2. The combination in a firearm of a frame, a breech-bolt, means to operate the breech-bolt, a firing-pin mounted in part in the breech-bolt and in part on the frame pivotally and slidably connected to the latter and serving as a guide or the breech-bolt in opening and closing, substantially as set forth.

3. A frame for firearms, consisting of a general cylindrical body with an applied magazine-supporting stud or projection at the front, and an applied mechanism-carrying stud or projection at the rear, substantially as set forth.

4. A frame for firearms, consisting of the body having the collar part 1ª at the forward end, the U-shaped form at the rear end and longitudinally slotted in a vertical plane between the forward and rear ends, and having the magazine-supporting stud 3 attached to the collar at the forward end, and the mechanism-supporting stud 29 attached to the U-shaped rear end, substantially as set forth.

5. The combination in and with the operating parts of a firearm of the breech-bolt mounted in part upon the firing-pin and adapted to swing around a pivot into locking and unlocking position with reference to the frame, of a seat adapted to engage the firing-pin and permit the swinging movement of the breech-bolt and firing-pin without becoming disengaged, substantially as set forth.

6. The combination in a firearm of the frame slotted longitudinally, a breech-bolt received in the slot of the frame and longitudinally recessed, a tubular firing-pin received within the longitudinal recess of the breech-bolt, a firing-spring within the firing-pin, a fixed pin secured in the rear of the frame and passing through slotted openings in the sides of the firing-pin and affording a support for the firing-pin, mechanism for operating the bolt, substantially as set forth.

7. The combination in a firearm of the frame, the breech-bolt arranged to have a rising-and-falling movement at the rear end of the barrel, mechanism for operating the breech-bolt, a firing-pin arranged in the breech-bolt and a safety-catch arranged in the frame at the rear end of the barrel and adapted to engage the breech-bolt to secure the same, a firing-pin arranged to operate said catch to unlock position and means for independently and manually operating said catch, substantially as set forth.

8. The combination in a firearm of a frame having longitudinal ways and recoil-shoulders, a relatively short breech-bolt having shoulders adapted to be moved in and out of engagement with the recoil-shoulders by a lateral movement and for longitudinal movement on said ways, a firing-pin slidably mounted in the breech-bolt at its forward end and mounted for a rocking and sliding movement in the frame at its rear end, and means for operating the breech-bolt and the firing-pin, substantially as set forth.

9. A frame for firearms consisting of a general cylindrical body with an applied stock and mechanism-supporting stud or projection at the front and an applied mechanism-supporting stud at the rear, substantially as set forth.

10. The combination in a firearm of a frame having longitudinal ways and recoil-shoulders, a breech-bolt having shoulders to engage the recoil-shoulders and adapted to slide on said ways, a firing-pin engaging with the breech-bolt at its forward end and longitudinally slotted at its rear end, a pin supported in the rear end of the frame and passing through the slot of the firing-pin and serving as a support and pivot for the bolt, and means for operating the bolt and operating the firing-pin, substantially as set forth.

810,572. PROCESS OF TREATING ORES. JOSEPH SAVELSBERG, Papenburg, Germany. Filed May 15, 1905. Serial No. 260,566.

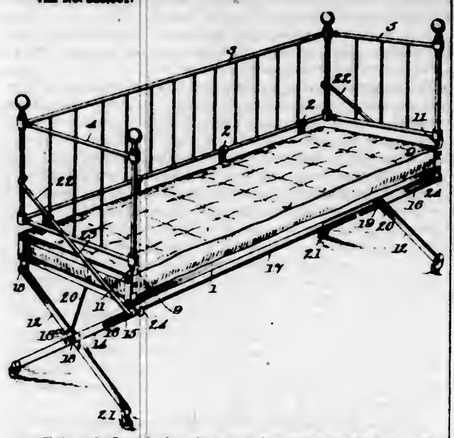
Claim.—1. The process of treating oxid ores, which consists in mixing the ore with sulfur-containing substance, and a fuel and blowing the mixture in a suitable furnace, substantially as described.

2. The process of treating oxid ores, which consists in mixing the ores with sulfur-containing substances, carbon and a flux and placing the mixture on a bed of glowing material, and blowing the charge, substantially as described.

3. The process of treating oxid ores, which consists in mixing the ore with sulfur-containing substances, pulverized carbon and a flux, charging the same into a suitable furnace onto a bed of glowing carbon and ore and blowing the charge to cause the sulfur to combine with the metal of the oxide to form sulfids and sinter the mass, substantially as described.

4. The process of treating oxid ores containing nickel, cobalt and copper, which consists in mixing the ore with sulfur, carbon and a flux, charging the same into a suitable furnace and blowing the mixture, substantially as described.

810,573. COLLAPSIBLE BED AND SIMILAR FURNITURE. FREDERICK C. SCHOFIELD, Washington, D. C. Filed Apr. 20, 1905. Serial No. 256,061.



Claim.—1. In a bed, sofa, or similar article of furniture, the combination with a body portion, of collapsible legs therefor, foldable means comprising operatively-connected longitudinal and end members, means for holding said end members locked in their opened positions, and stay-rods connecting said collapsible legs and foldable means.

2. In a bed, sofa or similar article of furniture, the combination with a body portion, of collapsible legs therefor, foldable means comprising operatively-connected longitudinal and end members, means for holding said end members locked in their opened positions, and jointed elbow stay-rods connecting said collapsible legs and foldable means.

3. In a bed, sofa or similar article of furniture, the combination with a body portion, of collapsible legs therefor, foldable means comprising operatively-connected longitudinal and end members, pintles formed on the end posts of said end members, apertured members adapted to receive said pintles and hold said end members in their opened position, and stay-rods connecting said collapsible legs and foldable means.

4. In a bed, sofa, or similar article of furniture, the combination with a body portion, of collapsible legs therefor, a foldable longitudinal member, foldable end members connected thereto, means for holding said end members locked in their opened positions, and stay-rods connecting said collapsible legs and longitudinal member.

5. In a bed, sofa or similar article of furniture, the combination with a body portion, of collapsible legs therefor, a foldable longitudinal member, foldable end members connected thereto, means for holding said end members locked in their opened positions, and stay-rods connecting said collapsible legs and longitudinal member and terminating in hooked extensions at their lower ends.

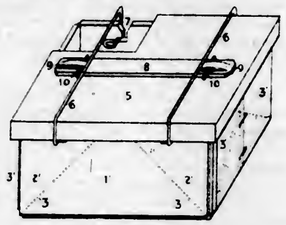
6. In a bed, sofa or similar article of furniture, the combination with a body portion, legs pivoted to the rear ends of said body portion and extending forwardly thereof, rearwardly-extending legs pivoted to said first legs, a sliding connection between the forward ends of said body portion and the upper ends of said rearwardly-disposed legs, a foldable longitudinal member, foldable end members connected thereto, means for holding said end members locked in their opened positions, and stay-rods pivotally connected to said longitudinal member and said rearwardly-disposed legs.

7. In a bed, sofa or similar article of furniture, the combination with a body portion, legs pivoted to the rear ends of said body portion and extending forwardly thereof, rearwardly-extending legs pivoted to said first legs, a pin-and-slot connection between the forward ends of said body portion and the upper ends of said rearwardly-disposed legs, a foldable longitudinal member, foldable end members connected thereto, means for holding said end members locked in their opened positions, and stay-rods pivotally connected to said longitudinal member and said rearwardly-disposed legs.

8. In a bed, sofa or similar article of furniture, the combination with a body portion, legs pivoted to the rear ends of said body portion and extending forwardly thereof, rearwardly-extending legs pivoted to said first legs, means for changing the pivotal connecting-axis of said legs, a sliding connection between the forward ends of said body portion and the upper ends of said rearwardly-disposed legs, a foldable longitudinal member, foldable end members connected thereto, means for holding said end members locked in their opened positions, and stay-rods pivotally connected to said longitudinal member and said rearwardly-disposed legs.

9. In a bed, sofa or similar article of furniture, the combination with a body portion, legs pivoted to the rear ends of said body portion and extending forwardly thereof, rearwardly-extending legs pivoted to said first legs, means for changing the pivotal connecting-axis of said legs comprising a plurality of apertures extending longitudinal of said legs, a sliding connection between the forward ends of said body portion and the upper ends of said rearwardly-disposed legs, a foldable longitudinal member, foldable end members connected thereto, means for holding said end members locked in their opened positions, and stay-rods pivotally connected to said longitudinal member and said rearwardly-disposed legs.

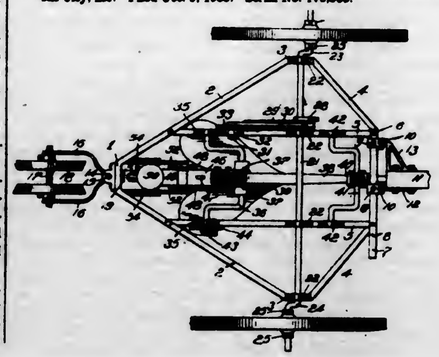
810,574. COLLAPSIBLE BOX. WILLIAM H. SEWELL, Winchester, Ky. Filed Feb. 24, 1903. Serial No. 96,743.



Claim.—1. A collapsible box, comprising a collapsible body, the edges of which are provided with bayonet-slots, in combination with a lid, and slides carried by said lid, the ends of said slides being hooked and projecting within the inner edges of the sides of the lid, whereby said ends are adapted to engage the bayonet-slots of the body for holding the lid thereon, and also to embrace the body, when collapsed and placed in the lid, for holding the body within the lid.

2. A collapsible box, comprising a body, the sides of which are formed of compound sections, the intermediate sections of said sides being adapted to fold inwardly, while the end sections are adapted to fold outwardly and upon the intermediate sections, thereby effecting a collapsing or folding of the box, the free edges of the sides being provided with bayonet-slots, ends carried by the bottom of the body, end flaps carried by the sides and embracing the ends of the bottom, and means for fastening said end flaps together, in combination with a lid, and slides carried by said lid, the ends of said slides being hooked and projecting within the inner edges of the sides of the lid, whereby said ends are adapted to engage the bayonet-slots of the body for holding the lid thereon, and also to embrace the body, when collapsed and placed in the lid, for holding the body within the lid.

810,575. COMBINED LISTER-PLOW AND PLANTER. ANDREW SHRADER, Frankfort, Kans., assignor of one-half to Linden Kirlin, Kansas City, Mo. Filed Oct. 9, 1903. Serial No. 176,365.



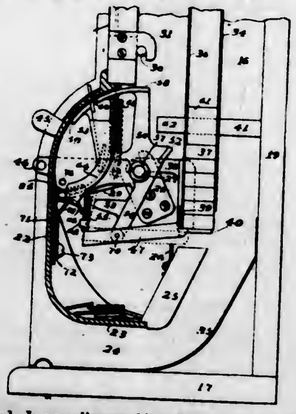
Claim.—1. In a machine of the character described, a suitable frame, a lister-plow suspended therefrom, means to raise and lower the plow, a transverse axle journaled in the frame and provided at its ends with rigid cranks extending at an angle to each other, wheels journaled on said cranks at approximately equal distances from and at opposite sides of the plow, a caster supporting the rear end of the frame and disposed in line with the plow, and means to rotate said axle and thereby simultaneously raise one and lower the other of its wheels without affecting the level of the plow.

2. In a machine of the character described, a suitable frame, a lister-plow suspended therefrom, means to raise and lower the plow, a planting mechanism suitably supported in longitudinal alinement with and rearward of the plow, a transverse axle journaled in the frame and provided at its ends with rigid cranks extending at an angle to each other, wheels journaled on said cranks at approximately equal distances from and at opposite sides of the plow, a caster supporting the rear end of the frame and disposed in line with the plow, and means to rotate said axle and thereby simultaneously raise one and lower the other of its wheels without affecting the level of the plow.

3. In a machine of the character described, a suitable frame, a transverse axle journaled therein and provided with cranks extending at an angle to each other, wheels journaled on said cranks and adjustable thereon laterally of the frame, a tongue hinged to the front portion of the frame, and a caster supporting the rear end of the frame.

4. In a machine of the character described, a suitable frame, a transverse axle journaled therein and provided with cranks extending at an angle to each other, wheels journaled on said cranks and adjustable thereon laterally of the frame, collars mounted on said cranks at opposite sides of each wheel, and adjustable laterally of the frame, to vary the distance between the wheels, a tongue hinged to the front portion of the frame, and a caster supporting the rear end of the frame.

810,576. COIN-CONTROLLED VENDING-MACHINE. ELIJAH F. SPAULDING, Troy, N. Y., assignor to Rudolph F. Bannerich, Brooklyn, N. Y. Filed May 19, 1905. Serial No. 261,143.



Claim.—1. In a vending-machine, the general cabinet or casing containing holders for the stacks of articles to be sold and having at its lower front vertical portion the front section 22 provided with an inwardly-extending lower member 23 above the discharge-passage for the goods sold, said front section forming within it a chamber to contain the operative mechanism and receive the coins, the latter being received upon said member 23, combined with means pivotally mounting said front section so that at the proper time the lower end thereof may be turned outwardly toward the front for enabling said member 23 to discharge the coins, and means for normally locking said front section 22 in rigid position; substantially as set forth.

2. In a vending-machine, the general cabinet or casing containing holders for the stacks of articles to be sold and having the pivotally-mounted lower front section forming within it a chamber to contain the operative mechanism and receive the coins, means intermediate the upper and lower ends of said front section for pivotally mounting the same, means for preventing the lower end of said section from being pushed inwardly, means for normally preventing the upper end of said section from being pushed inwardly and means for releasing the upper end of said section so that it may be pushed inwardly for tilting said section on its bearings and thereby effecting the discharge of the coins; substantially as set forth.

3. In a vending-machine, the general cabinet or casing containing holders for the stacks of articles to be sold and having the pivotally-mounted lower front section forming within it a chamber to contain the operative mechanism and receive the coins, said section having an inwardly-extending lower member, combined with a transverse bar to be normally engaged by said member, and a removable front section adapted to be locked within the casing and to engage the upper edge of said section for locking the latter stationary, said section at its upper edge and said removable front section having interengaging surfaces for preventing the movement of either of said sections, said pivotally-mounted section being capable of being tilted inwardly to discharge the coins when the said removable front section is withdrawn from the casing; substantially as set forth.

4. In a vending-machine, the general cabinet or casing containing the holders for the stacks of articles to be sold and the pivotally-mounted lower front section for said cabinet and forming within it a chamber to contain the operative mechanism and receive the coins, a transverse bar normally engaged by the lower end of said front section, the removable front 20 which normally engages the upper edge of said front section and locks the same, and means for locking said front, said front having hooks 31 to engage studs 30 provided in the casing; substantially as set forth.

5. In a vending-machine, the general cabinet or casing containing operative mechanism for receiving and testing the coins and dislodging the articles to be sold, the holders for the stacks of said articles, hooks carried by said holders for engaging supports therefor when said holders are in their normal position and studs located at a higher elevation in said casing for receiving said hooks when it is desired to partly remove said holders and replenish them with goods, said cabinet or casing having a removable front; substantially as set forth.

6. In a vending-machine, a holder for the articles to be sold, a pivotally-mounted frame affording a coin-chute and having an exposed handle whereby said frame may be manually turned on its pivot, and an ejector pivotally secured to and carried by said frame at a point below said chute, said ejector having means adjacent to the lower end of said chute for receiving the coin and holding the same and being so balanced that the coin, if of proper weight, will tilt said ejector into its operative position with relation to the lower end of said holder, whereby on the movement of said pivoted chute-frame said ejector will be moved to dislodge the article sold; substantially as set forth

7. In a vending-machine, a holder for the articles to be sold, a pivotally-mounted frame affording a coin-chute and having an exposed handle whereby said frame may be manually turned on its pivot, and an ejector pivotally secured to and carried by said frame at a point below said chute, said ejector having means adjacent to the lower end of said chute for receiving the coin and holding the same and being so balanced that the coin, if of proper weight, will tilt said ejector into its operative position with relation to the lower end of said holder, whereby on the movement of said pivoted chute-frame said ejector will be moved to dislodge the article sold, combined with means to dislodge the coin from said ejector during the movement of the same with said frame; substantially as set forth.

8. In a vending-machine, a holder for the articles to be sold, a pivotally-mounted frame affording a coin-chute and having an exposed handle whereby said frame may be manually turned on its pivot, and an ejector pivotally secured to and carried by said frame at a point below said chute, said ejector having means adjacent to the lower end of said chute for receiving the coin and holding the same and being so balanced that the coin, if of proper weight, will tilt said ejector into its operative position with relation to the lower end of said holder, whereby on the movement of said pivoted chute-frame said ejector will be moved to dislodge the article sold, said means for receiving and holding the coin comprising a plate having members at its opposite edges between which the coin passes and which, if the coin is of proper dimensions, will hold the same; substantially as set forth.

9. In a vending-machine, a holder for the articles to be sold, a pivotally-mounted frame affording a coin-chute and having an exposed handle whereby said frame may be manually turned on its pivot, and an ejector pivotally secured to and carried by said frame at a point below said chute, said ejector having means adjacent to the lower end of said chute for receiving the coin and holding the same and being so balanced that the coin, if of proper weight, will tilt said ejector into its operative position with relation to the lower end of said holder, whereby on the movement of said pivoted chute-frame said ejector will be moved to dislodge the article sold, said means for receiving and holding the coin comprising a plate having an oblique hook at one edge and a finger at the other edge between which hook and finger the coin will pass and which will hold the same if the coin is of proper thickness and diameter; substantially as set forth.

10. In a vending-machine, a holder for the articles to be sold, a movable frame affording the coin-chute which extends downwardly and outwardly toward the front wall of the machine, a transverse inwardly and downwardly extending plate below said chute and upon which the coins fall from said chute and which tilts said coins backwardly therefrom, and an ejector pivotally secured to and carried by said frame at a point below said chute and below the inner edge of said plate, said ejector having means adjacent to the inner edge of said plate for receiving a coin therefrom and holding the same and being so balanced that the coin if of proper weight will tilt said ejector with relation to the lower end of said holder, whereby on the inward movement of said ejector due to the movement of said frame the ejector will dislodge the article sold; substantially as set forth.

11. In a vending-machine, a holder for the articles to be sold, a pivotally-mounted frame carrying a chute to receive the coins from the coin-slot, means for operating said frame, and an ejector pivotally mounted on said frame and having at one end means for receiving and holding a coin and being so balanced that the coin, if of proper weight, will tilt said ejector into its operative position, said frame having means at the lower end of said chute for directing the coin to said receiving and holding means; substantially as set forth.

12. In a vending-machine, a holder for the articles to be sold, a pivotally-mounted frame carrying a chute to receive the coins from the coin-slot, means for operating said frame and a coin-controlled ejector carried by said frame for dislodging the articles sold, said frame having a stop 52, combined with a follower 61 mounted upon the stack of articles in said holder and having an arm 62 which, upon the depression of said frame at the time said holder should be replenished, will pass into engagement with said stop for locking said frame in an inoperative position; substantially as set forth.

13. In a vending-machine, a holder for the articles to be sold, a pivotally-mounted frame carrying a chute to receive the coins from the coin-slot, means for operating said frame, and a coin-controlled ejector for dislodging the articles as sold, said frame having a plate 58 which closes said coin-slot when said frame is operated, combined with means for locking said frame in its operated position with said plate closing said slot when said holder should be replenished; substantially as set forth.

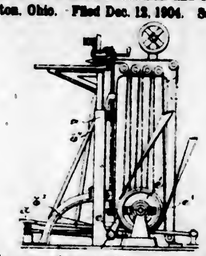
14. In a vending-machine, a holder for the articles to be sold, a pivotally-mounted frame carrying a chute to receive the coins from the coin-slot, means for operating said frame, and an ejector pivotally mounted on said frame and having at one end means for receiving and holding a coin and being so balanced that the coin, if of proper weight, will tilt said ejector into its operative position, said frame having means at the lower end of said chute for directing the coin to said receiving and holding means, and said machine being provided with a support for the inner end of said ejector when the latter is not in its operative position; substantially as set forth.

15. In a vending-machine, a holder for the articles to be sold, a pivotally-mounted frame carrying a chute to receive the coins from the coin-slot, means for operating said frame, and an ejector pivotally mounted on said frame and having at one end means for receiving and holding a coin and being so balanced that the coin, if of proper weight, will tilt said ejector into its operative position, said frame having means at the lower end of said chute for directing the coin to said receiving and holding means, and said machine being provided with a support for the inner end of said ejector when the latter is not in its operative position, combined with means for locking said pivotally-mounted frame in its operated position when so desired; substantially as set forth.

16. In a vending-machine, a holder for the articles to be sold and a pivotally-mounted frame 50 comprising the chute 51, plate 66 at the lower end of said chute to receive the coins, a downwardly-extending arm 54, a forwardly-extending finger 53 and an operating-lever 45, combined with a pivotally-mounted ejector carried by said arm 54 and having adjacent to said plate 66 coin-receiving means, said finger 53 being adapted to dislodge the coin from said coin-receiving means when said lever is operated; substantially as set forth.

17. In a vending-machine, the front casing having the coin-slot and window, a holder for the articles to be sold, and a pivotally-mounted frame carrying a chute to receive the coins from said slot and having an operating-lever projected through said casing, said frame also having plates 58, 59 between which a slot is provided to receive the coins and direct them into said chute, said plate 59 being normally at said window and said plate 58 normally closing the coin-slot when said lever is operated, combined with an ejector carried by said frame and provided with means for receiving the coin fed through said chute, means for dislodging the coin from said receiving means and means for locking said frame in its operated position with said plate 58 closing the coin-slot when said holder should be replenished; substantially as set forth.

810,577. PAGING-MACHINE. GEORGE STAHL, Dayton, Ohio, assignor of one-fourth to William P. Coffman and one-fourth to John I. Coffman, Dayton, Ohio. Filed Dec. 12, 1904. Serial No. 236,454.



Claim.—1. In a paging-machine, the combination with the printing mechanism, an arm for operating the same, a continuously-rotating part, a normally stationary cam, means for connecting said rotary part to said cam, and an adjustable cam-arm connected with the actuating-arm of the printing mechanism, substantially as and for the purpose set forth.

2. The combination of the printing mechanism with the actuating-arm, of an oscillating shaft, a spring on said shaft, a cam-arm also on said shaft, a cam contacting with said cam-arm, a rotating part, and a friction device between said rotating part and cam, substantially as specified.

3. In a paging-machine, the combination with printing mechanism, of a cam, driving mechanism, a shaft to be oscillated, a cam-arm connected to said shaft and contacting said cam, means for intermittently connecting said driving mechanism and said cam to give an initial movement to said cam, and means to complete the revolution of said cam by the pressure of said cam-arm on said cam, substantially as specified.

4. The combination of the printing device with a rotating pulley having a cone-shaped recess, a cone-shaped friction-clutch adapted to engage the same spring-pressed away from said pulley, a bell-crank connection to operate said friction-clutch, a foot-lever to operate said bell-crank connection, a cam connected to said clutch, a cam-arm adapted to engage the same, said cam-arm being mounted on a spring-actuated oscillating shaft, and a connection from said oscillating shaft to the printer, substantially as specified

5. In a paging-machine, the combination with a printing device of a support, a horizontal shaft supported in bearings therein, a cam carried by said shaft, a driving member on said shaft, a clutch between said driving member and said shaft, means for normally holding said clutch in its inoperative position, a lever engaging the movable part of said clutch to operate same, a shaft forming the main operating device of the machine to be operated, a cam-arm on said shaft contacting the cam on said horizontal shaft, and a spring to yieldingly hold said cam-arm in contact with said cam, substantially as specified.

810,578. KNITTING-MACHINE. BERNARD T. STERNE, Utica, N. Y. Filed Feb. 1, 1905. Serial No. 243,709.

Claim.—1. A knitting mechanism, whose needles knit alternately between raised needles, an auxiliary yarn-engaging mechanism suspended within the needles of the machine and operating between raised needles of the fabric-producing mechanism, comprising a dial, yarn-engaging devices on the dial and moving cam-engaging devices having movable cams mounted thereon, cam-operating detents projecting from the cams, a slide engaging the same for controlling the position of the said cams and means for raising the needles of the machine alternately.

2. In a circular independent-needle knitting-machine, means for projecting alternate needles up out of action, means for knitting with the alternate set of needles, means for causing these sets of needles to interchange their respective order of operations, and means

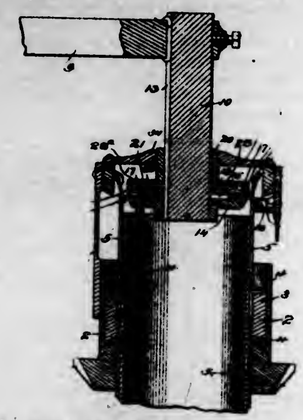
for drawing loops of fleecing-thread between the shanks of all the needles raised up out of action.

means for laying a loose thread on the outside of one of said sets of needles and on the inside of the other set.

affixed to the corset, a padded back-rest attached to the seat, the cor-

said ductile or compressible material, whereby relative rotation of

for drawing loops of fleecing-thread between the shanks of all the needles raised up out of action.



3. In a circular independent-needle knitting-machine, the combination with a cylinder, and a stationary dial arranged within the same, of fabric-knitting needles carried by said cylinder, means for projecting alternate needles up out of action, means for knitting with the alternate set of needles, means for causing said sets of needles to interchange their respective order of operation, and means carried by said dial for drawing loops of fleecing-thread between the shanks of the needles raised up out of action.

4. In a circular independent-needle knitting-machine, the combination of a cylinder, needles carried thereby, cams for projecting alternate needles up out of action, and for knitting with the alternate set of needles, said cams being formed for causing said sets of needles to interchange their respective order of operation, means for driving said needle-actuating cams, means for drawing loops of fleecing-thread between the shanks of the needles raised up out of action, and means driven by the cam-driving means for actuating said loop-drawing means.

5. In a circular independent-needle knitting-machine, the combination of driving means, means actuated thereby for projecting alternate needles up out of action, means for knitting with the alternate set of needles, means for causing said sets of needles to interchange their respective order of operation, a fixedly-supported shaft depending into the space surrounded by the needles, hooks supported by said shaft, means for actuating said hooks for drawing loops of fleecing-threads between the shanks of the needles raised up out of action, and means for communicating movement from the said driving means to said hook-actuating means.

6. In a circular independent-needle knitting-machine, the combination with a needle-cylinder, and needles operating vertically therein, of means for projecting alternate needles up out of action, means for knitting with the alternate set of needles, means for causing the sets of needles to interchange their respective order of operation, hooks for drawing loops of fleecing-thread between the shanks of the needles raised up out of action, and means for operating said hooks in alternation with respect to the active needles.

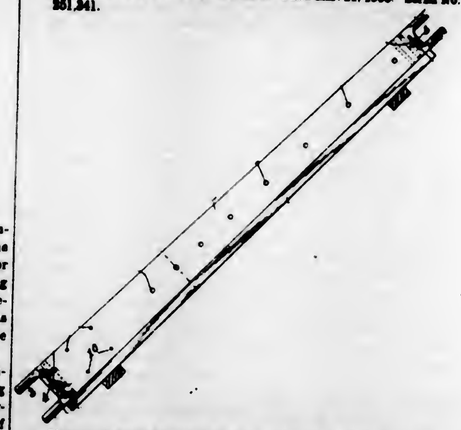
7. In a circular independent-needle knitting-machine, the combination with a needle-cylinder, and fabric-knitting needles carried thereby, of a dial arranged within the space inclosed by said needles, hooks carried by said dial and adapted at times to be projected beyond said needles for drawing loops of fleecing-thread between the shanks of the needles, and cams for alternately actuating alternate hooks.

8. In a knitting-machine, the combination with a cylinder, needles carried thereby, and a plurality of feeders for said needles, of means for projecting alternate needles up out of action, means for knitting with the alternate set of needles at every feeder, means for causing the sets of needles to interchange, and means for drawing loops of fleecing-threads between the shanks of the needles raised out of position.

9. In a circular independent-needle knitting-machine, the combination with a cylinder, and fabric-knitting needles carried thereby, of means for projecting alternate needles up out of action, means for knitting with the alternate set of needles, means for causing said sets of needles to interchange their respective order of operation, and means for laying a loose thread on the outside of one of said sets of needles and on the inside of the other set.

10. In a circular independent-needle knitting-machine, the combination with a cylinder, and fabric-knitting needles carried thereby, of means for projecting alternate needles up out of action, means for knitting with the alternate set of needles, means for causing said sets of needles to interchange their respective order of operation, and means moving about said cylinder for laying a loose thread on the outside of the inoperative needles and on the inside of the operating-needles.

810,579. **MOLD FOR MAKING CONCRETE FENCE-POSTS.** CARL B. STOKOE, Grand Haven, Mich. Filed Mar. 21, 1905. Serial No. 251,341.



Claim.—A mold for concrete fence-posts, comprising sides having a series of openings to receive fasteners, and a series of openings to receive stops, said sides also having recesses in their ends, bolts in the end recesses, and adjustable stops in the second-named series of openings.

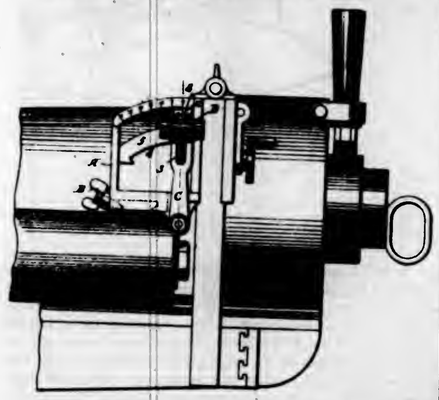
810,580. **SUPPORTING APPARATUS FOR PATHOLOGICAL CONDITIONS REQUIRING A SITTING POSITION.** DOUGLAS G. STORMS, Hamilton, Canada. Filed July 20, 1905. Serial No. 271,231.

Claim.—1. A supporting apparatus for the purpose specified, consisting of a laced corset preferably of leather or like material, a pad secured under each armhole, a seat secured to the corset, a back-rest attached to the seat, a block attached to each shoulder, a ring secured to each block, adjustable straps attaching the said corset-rings to an adjustable cross-bar of a frame, for supporting a patient in a sitting position for the drainage of pus after an abdominal operation, &c.

2. A supporting apparatus for pathological conditions requiring a patient to be placed in a sitting position after an operation, consisting of a leather jacket or corset formed in two vertical halves, each half having eyelet-holes for lacings, a tongue attached to each half to extend under the lacings, a pad under each armhole, a block on each shoulder, and a ring attached to each block, straps attached to each side of the jacket or corset, a soft lining attached to the inside of the corset, a seat formed with the bottom and two sides, the said sides having a series of buckles attached thereto to engage with the straps

affixed to the corset, a padded back-rest attached to the seat, the corset and seat held in an upright position by adjustable straps attached to the corset and to an adjustable cross-bar of a frame secured by any mechanical means to a bedstead all constructed substantially as and for the purpose specified.

810,581. **SIGHTING ATTACHMENT FOR GUNS.** ROBERT P. STOUT and FREDERICK G. HUGHES, South Bethlehem, Pa., assignors to Bethlehem Steel Company, South Bethlehem, Pa., a Corporation of Pennsylvania. Filed Aug. 30, 1905. Serial No. 276,268.



Claim.—1. A sighting device for guns consisting of a frame having a graduated arc, a pivoted arm one end of which travels over the arc, a level carried by the arm, means for moving the arm over the arc comprising a worm carried by the arm, a worm-rack engaged by the worm and carried by the frame, and a spring-brake engaging the worm, substantially as set forth.

2. A sighting device for guns, consisting of a frame having a graduated arc, a pivoted arm one end of which travels over said arc, a level carried by said arm, a rack secured to said frame and located between the pivot of said arm and said arc, and a worm-wheel carried by said arm and engaging with said rack, substantially as set forth.

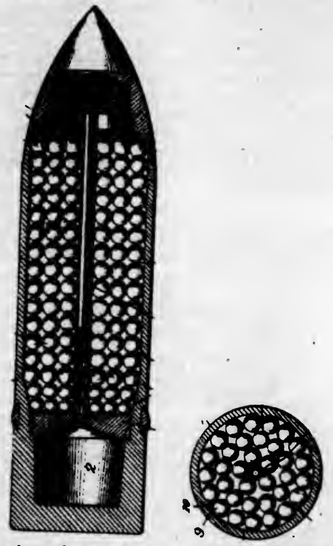
3. A sighting device for guns, comprising a frame having a graduated arc, a pivoted arm one end of which travels over said arc, a rack secured to said frame and located between the pivot of said arm and said arc, a worm-wheel carried by said arm and engaging with said rack, and a level secured to said arm between said worm-wheel and the end of said arm which travels over said arc, substantially as set forth.

4. A sighting device for guns, comprising a frame having a graduated arc, a pivoted arm one end of which travels over said arc, a level carried by said arm, a rack secured to said frame, a worm-wheel carried by said arm and adapted to engage with said rack, a brake-shoe mounted in said arm and movable longitudinally thereof to engage with said worm, and means for forcing said shoe against said worm, substantially as set forth.

5. A sighting device for guns, comprising a frame having a graduated arc, a pivoted arm one end of which travels over said arc, a rack secured to said frame and located between the pivot of said arm and said arc, a worm-wheel carried by said arm, said worm-wheel being adapted to engage with said rack and located between the pivot of said arm and said rack, and a level secured to said arm between said worm and the end of said arm which travels over said arc, said worm being mounted upon the back of said arm and projecting through a hole therein so that it may be engaged from the front, substantially as set forth.

810,582. **SHRAPNEL.** ROBERT P. STOUT, South Bethlehem, Pa., assignor to The Bethlehem Steel Company, South Bethlehem, Pa., a Corporation of Pennsylvania. Filed Sept. 29, 1905. Serial No. 280,666.

Claim.—1. In a shrapnel, the combination with a shell having chambers for the bursting charge and for the charge of balls, of a charge of hard-metal balls within said shell, a portion of ductile or compressible material within said shell and in contact with said charge of hard-metal balls, and means for clamping the balls upon said ductile or compressible material, whereby relative rotation of the balls and shell is prevented.

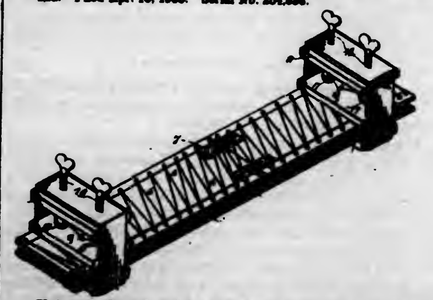


2. In a shrapnel, the combination with a shell having chambers for the bursting charge and for the charge of balls, of a charge of hard-metal balls within said shell, a layer of ductile or compressible balls within the shell and in contact with the charge of hard-metal balls, and means for clamping the hard balls upon said ductile or compressible balls, whereby relative rotation of the balls and shell is prevented.

3. In a shrapnel, the combination with a shell having chambers for the bursting charge and for the charge of balls, of longitudinal ribs upon the interior of said latter chamber, a charge of hard-metal balls within said chamber, a portion of lead balls within said chamber, and means for clamping said lead and hard balls tightly within the chamber and in engagement with said ribs, for the purpose set forth.

4. In a shrapnel, the combination with a shell having chambers for the bursting charge and for the charge of balls, of a charge of hard-metal balls within said shell, a layer of ductile or compressible balls between one end of the charge of hard balls and the chamber of the shell within which said charge is arranged, and means for clamping the hard balls upon said ductile or compressible balls, substantially as and for the purpose described.

810,583. **TROUSERS-PRESS.** MOSES H. STRAUS, Indianapolis Ind. Filed Apr. 10, 1905. Serial No. 254,636.



Claim.—1. In a knockdown trousers-press, the combination with upper and lower press-boards each of which are divided into hingedly-connected longer and shorter folding sections, of a removable moisture-absorbing covering stretched over each of said press-boards, and a detachable clamping means comprising removable

clamping-yokes whereby the upper and lower press-boards are held in clamped position, screw-plates carried thereby and press-board clamping-screws passing through said screw-plates.

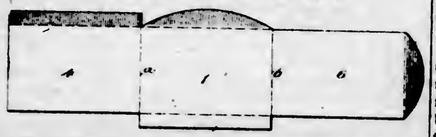
2. In a knockdown trousers-press, the combination with upper and lower press-boards each of which are divided into hingedly-connected longer and shorter folding sections, of a removable moisture-absorbing covering, means for stretching said moisture-absorbing covering over said press-boards, detachable clamping-yokes surrounding said upper and lower press-boards to hold the latter in their relative positions, and a clamping means comprising a lower pressure-plate, an upper pressure-plate, a thumb-screw plate, thumb-screws and friction-producing buttons of a yielding material pivoted on the ends of said thumb-screws.

810,584. LOCK. WILLIAM S. SUTTON, Rockford, Ill., assignor to American Company, Rockford, Ill., a Corporation of Illinois. Filed Dec. 9, 1903. Serial No. 134,554.

Claim.—1. A lock composed entirely of two integral parts, comprising a casing having a spring section separate from the main body portion and a pivot opening, and a catch stamped out of sheet metal and provided with a pivot lug and with a catch lug or bead adapted to engage the sides of the spring portion of the casing, substantially as and for the purpose described.

2. A two-part spring lock comprising a catch element made of sheet metal stamped with a pivot lug and a catch lug, and a casing and spring combined, stamped out of sheet metal and having a pivot opening and a separate spring section therein, substantially as described.

810,585. TWO-COMPARTMENT ENVELOP. LYMAN R. SWEET, Boston, Mass. Filed June 17, 1905. Serial No. 265,789.



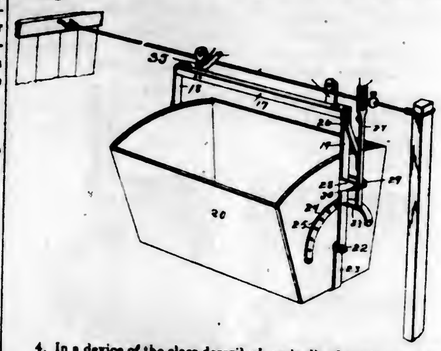
Claim.—A two-compartment envelop formed from a blank of three sections of equal length, the middle section having an adhesive lap on one side edge and a sealing-lap on its opposite side edge, one end section having a side edge adhesive lap, the other end section having an end sealing-lap, the end section having the side edge adhesive lap folded upon the middle section, the side edge adhesive lap of the middle section and the side edge adhesive lap of the end section folded upon said end section, the other end section folded upon the adhesive edge laps of the middle and of the first-folded end section whereby the back of the envelop is secured to the front and to the inner folded section forming thereby a compartment opening at the side sealing-lap, and a compartment opening at the end sealing-lap.

810,586. AUTOMATIC CARRIER AND SELF-DUMPING DEVICE. MARTIN J. STENSTAD and CARL G. RUDE, Sacred Heart, Minn. Filed Mar. 27, 1905. Serial No. 252,110.

Claim.—1. In a device of the class described, a track, a stop on the track, a carrier capable of longitudinal movement of the track, a pivotally-mounted carrier-box forming a portion of the carrier, a mechanism for locking the carrier-box in an upright position, and means designed to be engaged by the stop for releasing the mechanism which holds the carrier-box in an upright position and for returning the box to its point of starting away from the stop.

2. In a device of the class described, an inclined track, a carrier capable of longitudinal movement of the track, a carrier-box forming a part of the carrier, a stop on the track, a mechanism for securing the carrier-box in an upright position relative to the carrier, means designed to engage the stop on the track for releasing the mechanism for holding the carrier in an upright position and allowing it to dump and to force the carrier back to its point of starting.

3. In a device of the class described, an inclined track, a carrier capable of longitudinal movement of the track, a carrier-box forming a part of the carrier, an adjustable stop on the track, a mechanism for securing the carrier-box in an upright position relative to the carrier, and means designed to engage the stop on the track for releasing the mechanism for holding the carrier in an upright position and allowing it to dump and to force the carrier back to its point of starting.



4. In a device of the class described, an inclined track, a carrier capable of longitudinal movement of the track, a carrier-box forming a part of the carrier, a stop on the track, a mechanism for securing the carrier-box in an upright position relative to the carrier, and spring-actuated means designed to engage the stop on the track for releasing the mechanism for holding the carrier in an upright position and allowing it to dump and to force the carrier back to its point of starting.

5. In a device of the class described, an inclined track, a carrier capable of longitudinal movement of the track, a carrier-box forming a part of the carrier, an adjustable stop on the track, a mechanism for securing the carrier-box in an upright position relative to the carrier, and spring-actuated means designed to engage the stop on the track for releasing the mechanism for holding the carrier in an upright position and allowing it to dump and to force the carrier back to its point of starting.

6. In a device of the class described, a track, a stop on the track, a carrier capable of longitudinal movement of the track, a pivotally-mounted carrier-box forming a portion of the carrier, a mechanism for locking the carrier-box in an upright position, means designed to be engaged by the stop for holding the carrier-box in an upright position and for returning the box to its point of starting away from the stop, and means for retaining the carrier at its inner limit of movement.

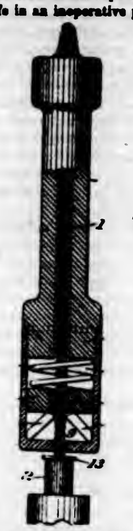
7. In a device of the class described, an inclined track, a stop near one end of the track, pulleys mounted on the track, a carrier-support connecting the pulleys, hanger-bars connected with the carrier-support, a carrier-box pivoted between the hanger and nearer its bottom portion than its top portion, a substantially semicircular plate having a series of openings therein, a pin designed to pass through an opening in one of the hangers and into one of the openings in the semicircular plate, a spring-actuated lever for maintaining the pin at its inner limit of movement, said lever designed to be engaged by the stop for taking advantage of the momentum of the carrier sliding from its inner limit to its outer limit of movement and return the same to its inner limit of movement.

8. In a device of the class described, a track, a stop on the track, a carrier capable of longitudinal movement of the track, a pivotally-mounted carrier-box forming a portion of the carrier, a mechanism for locking the carrier-box in an upright position, means for holding the box in an upright position, a pivotally-mounted forked lever connected with the said means, the forked portion thereof extending on each side of the track, and a spring for normally holding the lever away from the support to which it is pivoted, for the purposes stated.

810,587. ROPE-CUTTER. BARNETT D. TELLINGHAST and HARRY B. PENNEFATHER, McDonald, Pa. Filed Mar. 13, 1905. Serial No. 249,778.

Claim.—1. A rope-cutter having a casing or bowl provided with a chamber, an unattached gravity-actuated knife in the chamber, and means for maintaining the knife in an inoperative position.

2. A rope-cutter having a casing or bowl provided with a chamber, a plurality of unattached gravity-actuated knives in the chamber located on opposite sides of the rope to be cut, and means for maintaining each knife in an inoperative position.



3. A rope-cutter having a casing or bowl provided with a chamber, a plurality of unattached gravity-actuated knives in the chamber located on opposite sides of the rope to be cut, means for maintaining the knives in inoperative positions, and a spring-pressed plunger.

4. A rope-cutter having a casing or bowl provided with a chamber, a plurality of gravity-actuated knives in the chamber, a trip mechanism for maintaining the knives in inoperative position and for releasing the knives to permit them to fall into operative positions.

5. A rope-cutter having a casing or bowl, a connecting-stem attached thereto, said bowl and stem slotted for the purpose of applying the rope-cutter to a rope, said bowl provided with a chamber, a plurality of gravity-actuated knives in the chamber, means for maintaining the knives in inoperative positions and for releasing the knives to permit them to fall into operative positions.

6. A rope-cutter having a casing or bowl provided with a chamber, a connecting-stem attached to the bowl, a plurality of gravity-actuated knives in the chamber, a trip mechanism for maintaining the knives in inoperative positions and for releasing the knives to permit them to fall into operative positions, and a spring-pressed plunger above the knives.

7. A rope-cutter having a casing or bowl provided with a plurality of chambers, a connecting-stem attached to the bowl, a plurality of gravity-actuated knives in one chamber, a spring-pressed plunger above the knives located in another chamber, a trip mechanism for maintaining the knives in inoperative positions and for releasing the knives to permit them to fall into operative positions.

8. The combination with the rope to be cut, of a rope-cutter comprising a casing or bowl provided with a chamber, an unattached knife located in the chamber arranged in contact with the rope.

9. The combination with a rope to be cut, of a rope-cutter comprising a casing or bowl provided with a chamber, a plurality of unattached knives located in the chamber and arranged in contact with the rope on opposite sides thereof.

810,588. CAR-COUPLING. CHARLES H. TOMLINSON, Denver, Colo., assignor to The Tomlinson Coupler Company, Denver, Colo. Filed Feb. 10, 1905. Serial No. 245,043.

Claim.—1. The combination with a draw-head, of a pivoted coupling device located therein, a cam journaled in the draw-head and engaging the coupling device, an unlocking-lever accessible from the outside of the draw-head and connected to operate the cam for uncoupling purposes, and a pawl pivotally connected with the lever, the draw-head being provided with a recess having a stop adapted to engage the pawl of the opposite draw-head, whereby when the lever is thrown to the unlocked position, the pawl engages the stop and holds the locking lever and cam in the said position until the draw-heads are separated, substantially as described.

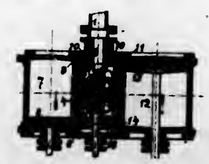
2. In a car-coupler, the combination with a draw-head, of a spring-actuated coupling device pivoted in the draw-head, an unlocking-cam engaging the coupling devices and a lever connected with the cam and provided with a jointed member adapted to protrude from the forward extremity of the draw-head for the purpose set forth.

3. In a car-coupler, the combination of two draw-heads having draw-bars pivotally connected with their respective cars, of spring-actuated pivoted coupling devices located within the draw-heads and adapted to protrude sufficiently to interlock when the draw-heads are in engagement, an unlocking-cam located in each draw-head and adapted to act on both coupling devices, a lever connected with the unlocking-cam of each draw-head and having a jointed member normally occupying a forward recess in its own draw-head, each draw-head, however, being provided with a forward recess which the said jointed member of the opposite draw-head enters, when the lever is thrown to the unlocking position, each draw-head having a stop located within the said recess, which stop is adapted to engage the jointed member and hold the parts in the unlocked position until the draw-heads are separated, substantially as described.

4. The combination with a draw-head and a coupling device located therein, of means for throwing the coupling device to the uncoupled position, said means including a lever fulcrumed on the draw-head and provided with a forwardly-projecting jointed member adapted to protrude from the forward extremity of the draw-head for the purpose set forth.

5. The combination with a draw-head and a coupling device located therein, of a pawl connected with the coupling device, protruding from the draw-head and adapted to engage the opposite draw-head to hold the coupling device of its own draw-head in the unlocked position until the two draw-heads are separated.

810,589. COMPOUND ENGINE. JEAN VENATOR, Cassel, Germany. Filed May 15, 1903. Serial No. 157,316.



Claim.—1. In a compound engine and in combination, two cylinders, a piston working in each cylinder, ports located in the opposite ends of each cylinder, a valve-chamber, a valve shiftable longitudinally therein, said valve having closed ends a steam-space between the ends of the valve and the ends of the valve-chamber for the passage of steam from one cylinder to the other, said valve having steam-passages extending longitudinally thereof, one of which opens out directly through one of the closed ends of the valve to communicate with the live-steam supply, and the other passage communicating with an exit for the used steam, said valve further having ports leading from the first passage to register with the ports of the first cylinder, and additional ports in communication with the second steam-passage to register with the ports of the second cylinder, substantially as described.

2. In a compound engine and in combination, two cylinders, a piston working in each cylinder, ports located at opposite ends of each cylinder, a valve-chamber, a valve shiftable therein controlling the ports, said valve having two steam-passages extending longitudinally of the same arranged side by side, one of which is in direct communication through one of its ends with the live steam, said valve further having ports leading from the latter passage designed to register with the ports of one of said cylinders, and additional ports for opening communication between the second passage in the valve and the other cylinder, and a third cylinder having a piston working therein and ports, adapted to communicate with the second passage in said valve.

810,590. VALVE. WILLIAM R. WHITEHEAD, Trenton, N. J. Filed Mar. 9, 1904. Serial No. 197,304.

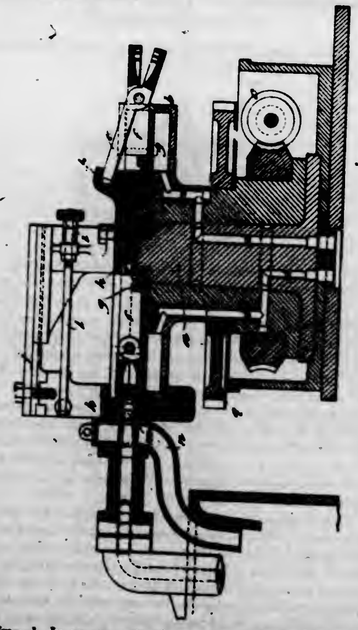
Claim.—1. In combination, a rotatable head carrying a plurality of needle-valves, a support for the head, and a part provided with a plurality of orifices into which the valves extend, the said part being rotatably movable for adjustment in a longitudinal direction with respect to the valves.

2. In combination, a rotatable head carrying a plurality of needle-valves, a support for the head, and a part provided with a plurality of orifices into which the valves extend, the said part having a screw-threaded connection with the head-support for longitudinal adjustment with respect to the valves.

3. In combination, a rotatable head carrying a plurality of needle-valves, a base-cap on which the head is mounted, and a chambered cap provided with a plurality of openings into which the valves extend, the said chambered cap having a screw-threaded connection with the base-cap and inclosing the valve-carrying head, for the purpose set forth.

4. In combination, a rotatable head part carrying a plurality of needle-valves, a support for the head part, and a cap part provided with a plurality of orifices into which the valves extend, one of said parts being rotatably mounted for the purpose of longitudinally adjusting said head part and cap part in relation to each other.

810,591. APPARATUS FOR CASTING PROJECTILES FOR SMALL-ARMS. FREDERICK WISE, Esher, England. Filed Oct. 23, 1903. Serial No. 178,304.



Claim.—1. In an apparatus for casting projectiles, the combination with a mold-wheel of molds sliding radially therein, means for moving the molds in and out in relation to the mold-wheel, means for forcing a jet of molten metal into the molds when they are in their retracted position, and means for thereafter moving the molds outward to deliver the cast projectile.

2. In an apparatus for casting projectiles for small-arms, the combination with a mold-wheel, of a series of molds carried by the mold-wheel adapted to move radially of the mold-wheel, each mold being composed of two parts hinged together, means for moving the molds radially of the wheel, and means for opening the molds when they are in their outward position, and closing them as they approach their casting position.

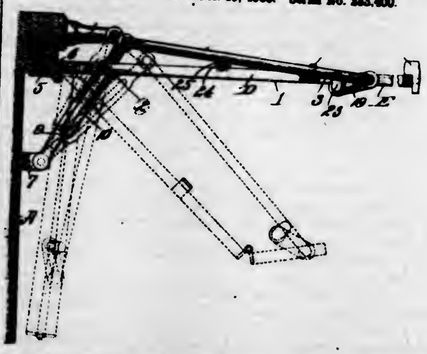
3. In an apparatus for casting projectiles for small-arms, the combination with a mold-wheel, of a plurality of molds mounted radially of the mold-wheel, a cam for moving the molds radially of the mold-wheel, and means for supplying to the molds molten metal under pressure when the molds are in their retracted position.

4. A mold-wheel, a series of scissor-shaped molds mounted in and arranged radially of the mold-wheel and adapted to move radially thereof, with means for moving the molds into the mold-wheel to receive a cast, and outwardly to discharge a bullet, substantially as described.

5. In an apparatus for casting projectiles, the combination with a mold-wheel, of a series of scissor-shaped molds mounted in the wheel, means for moving the molds radially of the wheel and means to cause the molds to open when moved outwardly and to close when moved inwardly.

6. In an apparatus for casting projectiles, the combination with a mold-wheel, of a series of scissor-shaped molds mounted in the wheel means for moving them radially thereof and means for automatically opening and closing the molds.

810,592. FOLDING GATE FOR CAR-PLATFORMS. HUBERT WITTE, St. Louis, Mo., assignor to St. Louis Car Company, St. Louis, Mo., a Corporation. Filed Oct. 19, 1905. Serial No. 283,400.



Claim.—1. In a folding gate of the character described, the combination of a rear swingingly-supported gate-section, a forward gate-section hinged to said rear section, a handle-rod loosely connected to said forward gate-section, and a swinging member in which said handle-rod is loosely supported, substantially as set forth.

2. In a folding gate of the character described, the combination of a rear swingingly-supported gate-section, a forward gate-section hinged to said rear section, a handle-rod loosely connected to said forward gate-section, a link loosely fitted to said handle-rod, and means for supporting said link, substantially as set forth.

3. In a folding gate of the character described, the combination of a rear swingingly-supported gate-section, a forward gate-section hinged to said rear section, a handle-rod loosely connected to said forward gate-section, a link loosely fitted to said handle-rod, means for supporting said link independent of either of said gate-sections, and a supporting-bar carried by said rear gate-section on which said link rests, substantially as set forth.

4. In a folding gate of the character described, the combination of a rear swingingly-supported gate-section, a forward gate-section hinged to said rear section, a handle-rod loosely connected to said forward gate-section, a link provided with a slot in which a member of said rear gate-section operates, and means for supporting said link; said link having loose connection with said handle-rod, substantially as set forth.

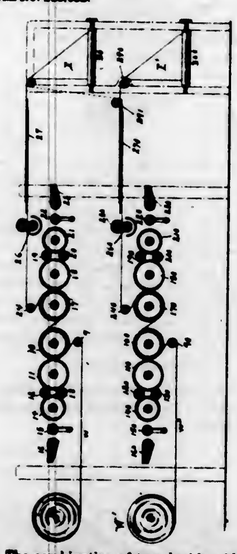
5. In a folding gate of the character described, the combination of a rear swingingly-supported gate-section, a forward gate-section hinged to said rear section, a handle-rod loosely connected to said forward gate-section, and a latch fixed to said handle-rod and arranged to engage said forward gate-section, substantially as set forth.

6. In a folding gate of the character described, the combination of a rear swingingly-supported gate-section, a forward gate-section hinged to said rear section, a handle-rod loosely connected to said forward gate-section, and a latch fixed to said handle-rod and arranged to engage said rear gate-section, substantially as set forth.

7. In a folding gate of the character described, the combination of a rear swingingly-supported gate-section, a forward gate-section hinged to said rear section, a handle-rod loosely connected to said forward section a latch-arm fixed to said handle-rod, and a latch-bolt carried by said latch-arm and arranged to engage either of said gate-sections, substantially as set forth.

8. In a folding gate of the character described, the combination of a rear swingingly-supported gate-section, a forward gate-section hinged to said rear section, a handle-rod loosely connected to said forward gate-section, oscillatory rod loosely fitted to said handle-rod, and means for supporting said oscillatory rod, substantially as set forth.

810,593. COMBINED ROTARY WEB PRINTING AND FOLDING MACHINE. HENRY A. W. WOOD, New York, N. Y., assignor to Campbell Printing Press & Manufacturing Company, New York, N. Y., a Corporation of New York. Filed Mar. 20, 1897. Renewed Apr. 14, 1905. Serial No. 256,062.



Claim.—1. The combination of two double-width, rotary web-printing machines, web-turners capacitated to bring one half the product of each press over the other half, and two longitudinal formers arranged one over the other with their backs to the printing-machines.

2. The combination of two double-width, rotary web-printing machines arranged one over the other, web-turners arranged to bring the product thereof into a single-width path, and two longitudinal formers arranged one over the other in said single-width path with their backs to the printing-machines.

3. The combination of two double-width, rotary web-printing machines, arranged one over the other, web-turners arranged to bring the products thereof into a single-width path, two longitudinal formers arranged one over the other in said single-width path, and transverse cutting and folding mechanism arranged to the side of each of said longitudinal formers and at right angles to the cylinders of the printing-machines.

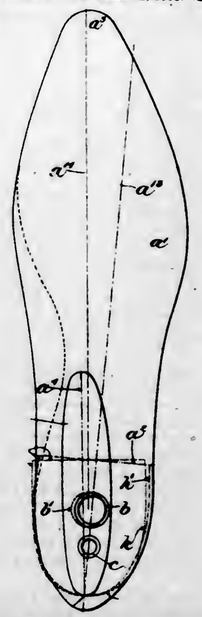
4. The combination of two double-width, rotary web-printing machines, web-turners arranged to bring the products thereof into a single-width path, two longitudinal formers arranged one over the other in said single-width path, and guides whereby the products of each press may be led independently to said formers or associated, or the product of both presses led over one of said formers.

5. The combination of two double-width rotary web-printing machines, web-turners arranged to bring the product thereof into a single-width path, two longitudinal formers arranged one over the other in said single-width path, transverse cutting and folding mechanism arranged to the side of each of said longitudinal formers, and at right angles to the cylinders of the printing-machines, one of said transverse cutting and folding mechanisms having combined therewith a collecting mechanism.

6. The combination of two double-width rotary web-printing machines, web-turners arranged to bring the product thereof into a single-width path, two longitudinal formers arranged one over the other in said single-width path, transverse cutting and folding mechanism arranged to the side of each of said longitudinal formers and at right angles to the cylinders of the printing-machines, one of said transverse cutting and folding mechanisms having combined therewith a collecting mechanism, and web-guides arranged so that the products of the two presses may be led separately to the two longitudinal formers, or together to the longitudinal former which has combined therewith the collecting mechanism.

7. The combination of two double-width rotary web-presses arranged one directly over the other, so that the two web-rolls are placed at the same end of the machine, slitters arranged on the center line of the machine, turners arranged to bring the products of the presses into a single-width pathway at one side of the center line of the press, two longitudinal folders or formers arranged one over the other in this single-width pathway, and transverse cutting and folding mechanism arranged on the other side of the center line of the press from the longitudinal folders or formers.

810,594. HEEL-ALINING MEANS FOR LASTS. ELLERY C. WRIGHT, Campello, Mass. Filed Jan. 12, 1905. Serial No. 240,675.



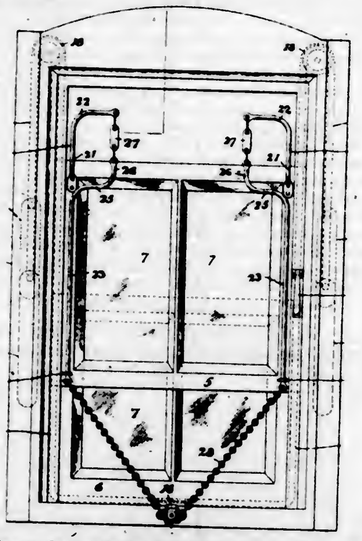
Claim.—1. A crooked last, whose heel contains two independent thimbles extending from the cone part way to the bottom of the last and having their axes extending perpendicular to the bottom in the plane of the center line extending midway between the opposite sides of the heel and at right angles to the normal breast-line of said heel.

2. The combination, with the usual jack-spindle socket of a crooked last, wherein the center line as herein described does not co-

incide with the normal trend of the last, of an alining-hole located in the wood of the last at the rear of said socket in the same axial plane with the axis of said socket extending at right angles to the normal breast-line of the heel.

3. A last of the kind herein described, wherein the center line diverges from the normal trend of the last, containing two independent thimbles located in the heel with their axes in the plane extending vertically of the bottom of the last midway between the opposite sides of the heel at the wider portions of the bottom edges thereof.

810,595. **AUTOMATIC FIRE-WINDOW.** GOTTLIEB YUNKER and GEORGE SCHWINN, Newark, N. J., assignors to The Newark Cornice and Skylight Works, a Corporation of New Jersey. Filed Oct. 9, 1905. Serial No. 281,927.



Claim.—1. In a window, the combination of a frame, an upper sash therein, a bracket projecting from said sash above its top, a fusible link depending from said bracket, means normally holding the sash closed and means extending from said link below the bottom of the sash and adapted to secure the same in open position.

2. In a window, the combination of a frame, an upper sash therein, a bracket projecting from said sash above its top, a fusible link depending from said bracket, means normally holding the sash closed, and means attached to said link for holding the sash in open position.

3. In a window, the combination of a frame, an upper sash therein, a bracket projecting from said sash above its top, a fusible link depending from said bracket, means normally holding the sash closed, a slideway upon the side of said sash, and means extending through said slideway from said link below the bottom of the sash and adapted to hold the sash in open position.

4. In a window, the combination of a frame, an upper sash therein, a bracket projecting from said sash above its top, a fusible link depending from said bracket, means normally holding the sash closed, a slideway upon the side of the sash, a rod slidably mounted in said slideway and connected at its upper ends to said link, and means connected to the lower end of said rod for fastening the sash in open position.

5. In a window, the combination of a frame, an upper sash therein, brackets projecting from said sash above its top, fusible links depending from said brackets, means normally holding the said sash closed, slideways upon the opposite sides of the sash, rods slidably mounted one in each slideway and connected at their upper ends to said links, and a chain connecting the lower ends of said rods.

6. In a window, the combination of a frame, an upper sash therein, brackets projecting from said sash above its top, fusible links depending from said brackets, means normally holding the sash closed, eyes upon the opposite sides of said sash near its lower end, rods slidably mounted in said eyes and connected at their upper ends to said links a chain connecting the lower ends of said rods, and means upon the window-frame for engaging said chain.

7. In a window, the combination of a frame, an upper sash therein, brackets projecting from said sash above its top, fusible links depending from said brackets, means normally holding the sash closed, eyes upon the opposite sides of said sash near its lower end, rods slidably mounted in said eyes and connected at their upper ends to said links a chain connecting the lower ends of said rods, and a pulley upon the lower end of the window-frame over which said chain may be hooked.

810,596. **SPRING-JACK WEDGE.** GUSTAVE A. SUNDEL, New York, N. Y., assignor to J. H. Bunnell and Company, a Corporation of New York. Filed Nov. 17, 1904. Serial No. 233,070.

Claim.—1. In a spring-jack wedge or the like, the combination of metallic strips and an insulating-body separating them, with conducting-wires electrically connected to the said strips and sewed to said body.

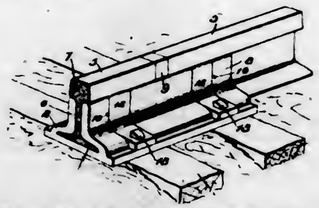
2. In a spring-jack wedge or the like, the combination of metallic strips, and an insulating-body separating said strips and provided with two sets of perforations, with covered conducting-wires passing through one set of perforations in said body and electrically connected to said strips, and binding-threads passing through the second set of perforations and through the covers of the wires to secure the wires to the body.

810,597. **SHINGLING-HATCHET.** ROBERT B. ALLISON, Topeka, Kans. Filed Jan. 23, 1905. Serial No. 242,417.

Claim.—1. A hatchet-blade provided with a seat, in combination with a gage having its intermediate portion rotatably mounted in the seat, and its terminal portions formed into semicylindrical shoulders that project beyond both sides of the blade, the flat sides of the cylindrical shoulders being both disposed in alinement.

2. A hatchet-blade provided with a seat, in combination with a gage having its intermediate portion held combined with the seat by frictional engagement with the walls thereof, the terminal portions of the gage being cut away to form semicylindrical shoulders that project laterally beyond the sides of the blade, the flat sides of the cylindrical shoulders being both disposed in alinement.

810,598. **RAIL-JOINT.** WALLACE W. ANGLIN, Buffalo, Mo., assignor of one-half to John A. Lamun, Buffalo, Mo. Filed Oct. 19, 1905. Serial No. 283,485.



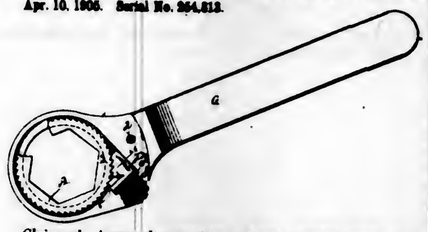
Claim.—1. In a rail-joint the combination with a base having integral flanges thereon, one of said flanges having slots therein; of rails interposed between the flanges and upon the base, the base-flanges of said rails being overlapped by the flanges on the base and said base-flanges having recesses registering with the slots, and holding-blocks secured within the slots and recesses.

2. In a rail-joint the combination with a base and means integral with the base for engaging opposite faces of rails, one of said means having slots therein; of rails disposed between the flanges and upon the base and having recesses therein registering with the slots, and means secured within the slots and recesses for holding the rails against longitudinal movement.

3. A rail-joint comprising a base, integral rail-engaging flanges on the base, one of said flanges having slots therein extending from top to bottom thereof, and locking-blocks adapted to be seated and secured within the slots and to engage recesses in rails between the flanges.

4. A rail-joint comprising a base, rail-engaging flanges integral with and extending from the base, one of said flanges having slots extending from top to bottom thereof, locking-blocks detachably mounted and fitting snugly within the slots and adapted to be seated within recesses in base-flanges of rails within the joint, and a partition connecting the flanges on the base, said partition having an extension adapted to rest between and conforming in contour to the heads of rails.

810,599. **WRENCH.** EUGENE K. ANDERSON, Green Bay, Wis. Filed Apr. 10, 1905. Serial No. 254,813.

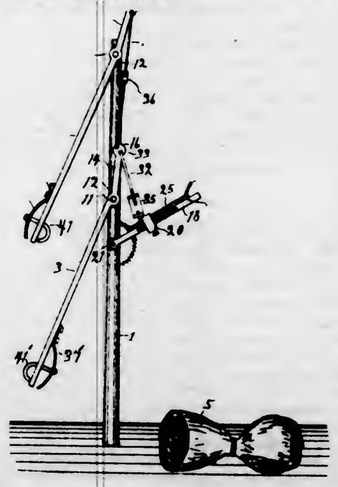


Claim.—1. A wrench comprising a head, a ratchet having loose fit in the head and provided with an angular aperture or socket, and an angular partly-concave block having play in a corresponding depression of said head at a tangent to the ratchet-space, the concavity of the block being provided with a plurality of teeth matching those of the ratchet from which said block has yield in a direction at a right angle to the outer faces of the proximate teeth of said ratchet.

2. A wrench comprising a head, a ratchet having loose fit in the head and provided with an angular aperture or socket, an angular partly-concave block having play in a corresponding depression of said head at a tangent to the ratchet-space, the concavity of the block being provided with a plurality of teeth matching those of the ratchet from which the block has yield in a direction at a right angle to the outer faces of proximate teeth of said ratchet, and a spring arranged under tension to resist yield of said block.

3. A wrench comprising a head, a ratchet loose in the head and having an angular aperture or socket, a pawl-block having play in a space within said head at a tangent to the ratchet-space, the back of the block being convex in opposition to the long side of said play-space; and a spring arranged under tension against the pawl-block in a direction approximating a right angle to the outer faces of the ratchet-teeth opposing said block.

810,600. **MAIL-CRANE.** JAMES L. ATHEY, Woodbine, Iowa. Filed Oct. 26, 1905. Serial No. 284,600.



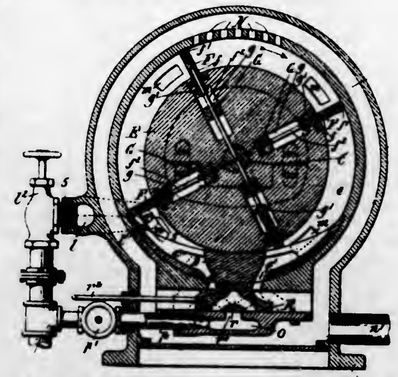
Claim.—1. A mail-crane, in combination; comprising a substantially vertically disposed staff; arms pivotally mounted upon said staff; each of said pivotally-mounted arms being extended longitudinally to form a lever thereon; a link connecting said levers; mechanism attached to said link; and means to control said mechanism.

2. A mail-crane, in combination; comprising a substantially vertically disposed staff; arms pivotally mounted upon said staff; each of said pivotally-mounted arms being extended lengthwise to form a lever thereon; a first link; a second link; said first link forming a pivotal connection between said levers; said second link attached to said first link; mechanism attached to said second link; and means to control said mechanism.

3. A mail-crane, in combination; comprising a substantially vertically disposed supporting-staff; a first sustaining-arm; a second sustaining-arm; a first lever; a second lever; a third lever; a first link; a second link; each of said first and second sustaining-arms being pivotally mounted upon said substantially vertically disposed supporting-staff; said first sustaining-arm being extended beyond its pivotal mounting in a direction substantially lengthwise with said sustaining-arm, to form said first lever; said second sustaining-arm being extended beyond its pivotal mounting in a direction substantially lengthwise to form said second lever; said first link being pivotally mounted upon and forming a connection between said first and second levers; said third lever being mounted upon said supporting-staff; said second link being pivotally mounted upon and forming a connection between said first link and said third lever; mechanism attached to said third lever and means to control said mechanism.

4. A mail-crane, in combination; a suitable supporting-staff; a ratchet-controlled weighted lever pivotally mounted upon said supporting-staff; an upper and a lower supporting-arm pivotally mounted upon said supporting-staff; mail-sack-engaging means attached to said upper and lower supporting-arms; and a link connection between said upper and lower supporting-arm; and said ratchet-controlled weighted lever, substantially as described.

810,601. **ROTARY ENGINE.** BENJAMIN F. AUGUSTINE, Buffalo, N. Y. Filed Aug. 28, 1905. Serial No. 276,149.



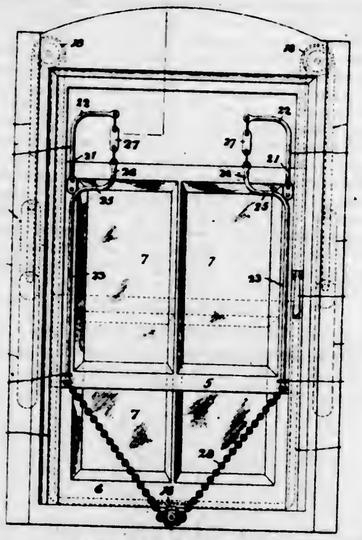
Claim.—1. The combination of a rotary core, a cylinder surrounding said core and contacting therewith to form an abutment, pistons carried by said core and traveling in contact with the inner surface of said cylinder, means for admitting the motive fluid into the cylinder at one side of said abutment and cutting it off to act expansively, a supplemental exhaust-port at the opposite side of the abutment, and a main exhaust-port between said admission means and said supplemental exhaust-port, said abutment having a by-pass passage whereby the fluid can pass by a piston in contact with said abutment and exert its pressure between the preceding piston and said abutment substantially until said preceding piston reaches said main exhaust-port and the succeeding piston passes off of said abutment, substantially as set forth.

2. The combination of a rotary core, a cylinder surrounding said core and contacting therewith to form an abutment, pistons carried by said core and traveling in contact with the inner surface of said cylinder, an admission-port in the end of the cylinder at one side of said abutment, a disk secured to the end of said core and having ports which cooperate with said admission-port to cut off the fluid to

incide with the normal trend of the last, of an aligning-hole located in the wood of the last at the rear of said socket in the same axial plane with the axis of said socket extending at right angles to the normal breast-line of the heel.

3. A last of the kind herein described, wherein the center line diverges from the normal trend of the last, containing two independent thimbles located in the heel with their axes in the plane extending vertically of the bottom of the last midway between the opposite sides of the heel at the wider portions of the bottom edges thereof.

810,595. **AUTOMATIC FIRE-WINDOW.** GOTTLIEB YUNKER and GEORGE SCHWINN, Newark, N. J., assignors to The Newark Cornice and Skylight Works, a Corporation of New Jersey. Filed Oct. 9, 1905. Serial No. 281,987.



Claim.—1. In a window, the combination of a frame, an upper sash therein, a bracket projecting from said sash above its top, a fusible link depending from said bracket, means normally holding the sash closed and means extending from said link below the bottom of the sash and adapted to secure the same in open position.

2. In a window, the combination of a frame, an upper sash therein, a bracket projecting from said sash above its top, a fusible link depending from said bracket, means normally holding the sash closed, and means attached to said link for holding the sash in open position.

3. In a window, the combination of a frame, an upper sash therein, a bracket projecting from said sash above its top, a fusible link depending from said bracket, means normally holding the sash closed, a slideway upon the side of said sash, and means extending through said slideway from said link below the bottom of the sash and adapted to hold the sash in open position.

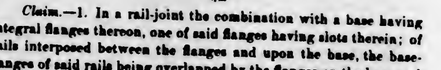
4. In a window, the combination of a frame, an upper sash therein, a bracket projecting from said sash above its top, a fusible link depending from said bracket, means normally holding the sash closed, a slideway upon the side of the sash, a rod slidably mounted in said slideway and connected at its upper ends to said link, and means connected to the lower end of said rod for fastening the sash in open position.

5. In a window, the combination of a frame, an upper sash therein, brackets projecting from said sash above its top, fusible links depending from said brackets, means normally holding the said sash closed, slideways upon the opposite sides of the sash, rods slidably mounted one in each slideway and connected at their upper ends to said links, and a chain connecting the lower ends of said rods.

6. In a window, the combination of a frame, an upper sash therein, brackets projecting from said sash above its top, fusible links depending from said brackets, means normally holding the sash closed, eyes upon the opposite sides of said sash near its lower end, rods slidably mounted in said eyes and connected at their upper ends to said links a chain connecting the lower ends of said rods, and means upon the window-frame for engaging said chain.

7. In a window, the combination of a frame, an upper sash therein, brackets projecting from said sash above its top, fusible links depending from said brackets, means normally holding the sash closed, eyes upon the opposite sides of said sash near its lower end, rods slidably mounted in said eyes and connected at their upper ends to said links a chain connecting the lower ends of said rods, and a pulley upon the lower end of the window-frame over which said chain may be hooked.

810,596. **SPRING-JACK WEDGE.** GUSTAVE A. SUHRBIER, New York, N. Y., assignor to J. H. Bunnell and Company, a Corporation of New York. Filed Nov. 17, 1904. Serial No. 233,070.



Claim.—1. In a spring-jack wedge or the like, the combination of metallic strips and an insulating-body separating them, with conducting-wires electrically connected to the said strips and sewed to said body.

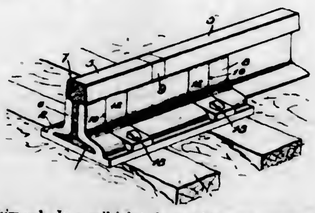
2. In a spring-jack wedge or the like, the combination of metallic strips, and an insulating-body separating said strips and provided with two sets of perforations, with covered conducting-wires passing through one set of perforations in said body and electrically connected to said strips, and binding-threads passing through the second set of perforations and through the covers of the wires to secure the wires to the body.

810,597. **SHINGLING-HATCHET.** ROBERT B. ALLISON, Topeka, Kans. Filed Jan. 23, 1905. Serial No. 242,417.

Claim.—1. A hatchet-blade provided with a seat, in combination with a gage having its intermediate portion rotatably mounted in the seat, and its terminal portions formed into semicylindrical shoulders that project beyond both sides of the blade, the flat sides of the cylindrical shoulders being both disposed in alinement.

2. A hatchet-blade provided with a seat, in combination with a gage having its intermediate portion held combined with the seat by frictional engagement with the walls thereof, the terminal portions of the gage being cut away to form semicylindrical shoulders that project laterally beyond the sides of the blade, the flat sides of the cylindrical shoulders being both disposed in alinement.

810,598. **RAIL-JOINT.** WALLACE W. ANGLIN, Buffalo, Mo., assignor of one-half to John A. Lamun, Buffalo, Mo. Filed Oct. 19, 1905. Serial No. 283,485.



Claim.—1. In a rail-joint the combination with a base having integral flanges thereon, one of said flanges having slots therein; of rails interposed between the flanges and upon the base, the base-flanges of said rails being overlapped by the flanges on the base and said base-flanges having recesses registering with the slots, and holding-blocks secured within the slots and recesses.

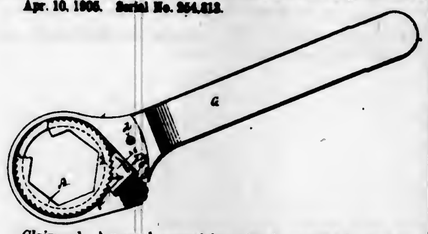
2. In a rail-joint the combination with a base and means integral with the base for engaging opposite faces of rails, one of said means having slots therein; of rails disposed between the flanges and upon the base and having recesses therein registering with the slots, and means secured within the slots and recesses for holding the rails against longitudinal movement.

3. A rail-joint comprising a base, integral rail-engaging flanges on the base, one of said flanges having slots therein extending from

top to bottom thereof, and locking-blocks adapted to be seated and secured within the slots and to engage recesses in rails between the flanges.

4. A rail-joint comprising a base, rail-engaging flanges integral with and extending from the base, one of said flanges having slots extending from top to bottom thereof, locking-blocks detachably mounted and fitting snugly within the slots and adapted to be seated within recesses in base-flanges of rails within the joint, and a partition connecting the flanges on the base, said partition having an extension adapted to rest between and conforming in contour to the heads of rails.

810,599. **WRENCH.** EUGENE K. ANDERSON, Green Bay, Wis. Filed Apr. 10, 1905. Serial No. 254,813.

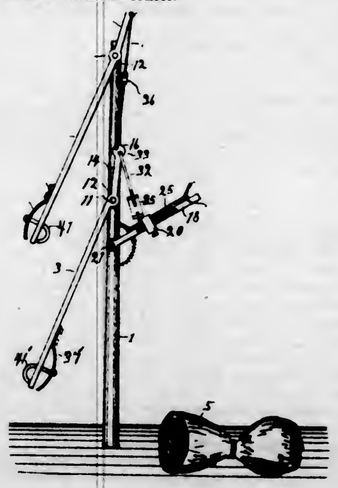


Claim.—1. A wrench comprising a head, a ratchet having loose fit in the head and provided with an angular aperture or socket, and an angular partly-concave block having play in a corresponding depression of said head at a tangent to the ratchet-space, the concavity of the block being provided with a plurality of teeth matching those of the ratchet from which said block has yield in a direction at a right angle to the outer faces of the proximate teeth of said ratchet.

2. A wrench comprising a head, a ratchet having loose fit in the head and provided with an angular aperture or socket, an angular partly-concave block having play in a corresponding depression of said head at a tangent to the ratchet-space, the concavity of the block being provided with a plurality of teeth matching those of the ratchet from which the block has yield in a direction at a right angle to the outer faces of proximate teeth of said ratchet, and a spring arranged under tension to resist yield of said block.

3. A wrench comprising a head, a ratchet loose in the head and having an angular aperture or socket, a pawl-block having play in a space within said head at a tangent to the ratchet-space, the back of the block being convex in opposition to the long side of said play-space; and a spring arranged under tension against the pawl-block in a direction approximating a right angle to the outer faces of the ratchet-teeth opposing said block.

810,600. **MAIL-CRANE.** JAMES L. ATHEY, Woodbine, Iowa. Filed Oct. 26, 1905. Serial No. 284,609.



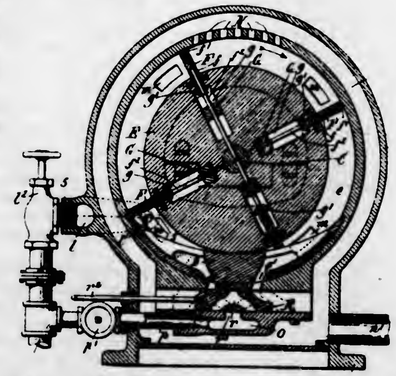
Claim.—1. A mail-crane, in combination; comprising a substantially vertically disposed staff; arms pivotally mounted upon said staff; each of said pivotally-mounted arms being extended longitudinally to form a lever thereon; a link connecting said levers; mechanism attached to said link; and means to control said mechanism.

2. A mail-crane, in combination; comprising a substantially vertically disposed staff; arms pivotally mounted upon said staff; each of said pivotally-mounted arms being extended lengthwise to form a lever thereon; a first link; a second link; said first link forming a pivotal connection between said levers; said second link attached to said first link; mechanism attached to said second link; and means to control said mechanism.

3. A mail-crane, in combination; comprising a substantially vertically disposed supporting-staff; a first sustaining-arm; a second sustaining-arm; a first lever; a second lever; a third lever; a first link; a second link; each of said first and second sustaining-arms being pivotally mounted upon said substantially vertically disposed supporting-staff; said first sustaining-arm being extended beyond its pivotal mounting in a direction substantially lengthwise with said sustaining-arm, to form said first lever; said second sustaining-arm being extended beyond its pivotal mounting in a direction substantially lengthwise to form said second lever; said first link being pivotally mounted upon and forming a connection between said first and second levers; said third lever being mounted upon said supporting-staff; said second link being pivotally mounted upon and forming a connection between said first link and said third lever; mechanism attached to said third lever and means to control said mechanism.

4. A mail-crane, in combination; a suitable supporting-staff; a ratchet-controlled weighted lever pivotally mounted upon said supporting-staff; an upper and a lower supporting-arm pivotally mounted upon said supporting-staff; mail-sack-engaging means attached to said upper and lower supporting-arms; and a link connection between said upper and lower supporting-arm; and said ratchet-controlled weighted lever, substantially as described.

810,601. **ROTARY ENGINE.** BENJAMIN F. AUGUSTINE, Buffalo, N. Y. Filed Aug. 28, 1905. Serial No. 276,149.



Claim.—1. The combination of a rotary core, a cylinder surrounding said core and contacting therewith to form an abutment, pistons carried by said core and traveling in contact with the inner surface of said cylinder, means for admitting the motive fluid into the cylinder at one side of said abutment and cutting it off to act expansively, a supplemental exhaust-port at the opposite side of the abutment, and a main exhaust-port between said admission means and said supplemental exhaust-port, said abutment having a by-pass passage whereby the fluid can pass by a piston in contact with said abutment and exert its pressure between the preceding piston and said abutment substantially until said preceding piston reaches said main exhaust-port and the succeeding piston passes off of said abutment, substantially as set forth.

2. The combination of a rotary core, a cylinder surrounding said core and contacting therewith to form an abutment, pistons carried by said core and traveling in contact with the inner surface of said cylinder, an admission-port in the end of the cylinder at one side of said abutment, a disk secured to the end of said core and having ports which cooperate with said admission-port to cut off the fluid to

set expansively, an exhaust-port, said abutment having a by-pass passage whereby the fluid from the admission-port can pass by a piston in contact with said abutment and exert its pressure between the preceding piston and said abutment substantially until said preceding piston reaches said exhaust-port and the succeeding piston passes off of said abutment, substantially as set forth.

3. The combination of a rotary core, a cylinder surrounding said core and contacting therewith to form an abutment, pistons carried by said core and traveling in contact with the inner surface of said cylinder, an admission-port in the end of the cylinder at one side of said abutment, a disk secured to the end of said core and having ports which coöperate with said admission-port to cut off the fluid to act expansively, an exhaust-port, said abutment having by-pass passages in its opposite sides whereby the fluid can pass by a piston in contact with said abutment, ports connecting with said by-pass passages, and a reversing-valve controlling said ports and adapted in one position to close the port at the side of the abutment adjacent to said admission-port and open the other port to serve as a supplemental exhaust-port, substantially as set forth.

4. The combination of a rotary core, a surrounding cylinder concentric with said core and having an eccentric portion which contacts with the core to form an abutment, pistons carried by said core and traveling in contact with said cylinder, admission-ports in the ends of the cylinder at one side of said abutment, a valve controlling the supply thereto, disks secured to the ends of the core and having ports which coöperate with said admission-ports to cut off the fluid to act expansively, said cylinder having a main exhaust-port and also ports at opposite sides of said abutment, a fluid-supply, and a reversing-valve controlling said fluid-supply and ports at opposite sides of the abutment and constructed to close the port at the side of the abutment next to the admission-ports and open the port at the opposite side of the abutment to serve as a supplemental exhaust-port, or to connect the last-mentioned port with said fluid-supply and open the port next to the admission-port for reversing the engine, substantially as set forth.

5. The combination of a rotary core, a cylinder surrounding said core and contacting therewith at one side to form an abutment, pistons carried by said core and traveling in contact with the inner surface of said cylinder, means for admitting motive fluid to the cylinder at one side of said abutment and cutting it off to act expansively, a valve controlling the supply of fluid to said means, and a reversing mechanism independent of said cut-off mechanism for admitting and exhausting motive fluid to and from the cylinder at opposite sides of said abutment, substantially as set forth.

6. The combination of a rotary core, a cylinder surrounding the core and contacting therewith at one side to form an abutment, pistons slidably mounted in radial guides in said core, means for holding said pistons out against the inner surface of the cylinder, counterweights connected to said pistons, stops to limit the outward movement of the pistons, shoes on said pistons which are pressed against the cylinder independently of the means for holding said pistons out, and means for admitting an exhausting fluid to and from the cylinder, substantially as set forth.

7. The combination of a rotary core, a cylinder surrounding said core and contacting therewith at one side to form an abutment, pistons carried by said core and traveling in contact with the inner surface of said cylinder, means for admitting motive fluid to the cylinder at one side of said abutment and cutting it off to act expansively, admission and exhaust ports at opposite sides of said abutment, and a reversing-valve controlling said ports to admit and exhaust motive fluid to and from the cylinder at opposite sides of said abutment, said reversing-valve being also constructed and arranged to close the admission and exhaust port at the side of the abutment adjacent to said cut-off means and open the admission and exhaust port at the opposite side of the abutment, substantially as set forth.

8. The combination of a rotary core, a cylinder surrounding the core and contacting therewith at one side to form an abutment, pistons slidably mounted in radial guides in said core, means for holding said pistons out against the inner surface of the cylinder, stops to limit the outward movement of said pistons, counterweights connected to said pistons and movable in guides in said core, and means for admitting and exhausting fluid to and from the cylinder, substantially as set forth.

9. The combination of a rotary core, a cylinder surrounding the core and contacting therewith at one side to form an abutment, diametrically opposite pistons arranged to slide in radial guides in said core, a counterweight arranged diametrically opposite to each piston to slide in a radial guide in the core, rods connecting each piston and the opposite counterweight and passing through the counterweight for the opposite piston, means for holding the pistons in contact with the cylinder, and means for admitting and exhausting fluid to and from the cylinder, substantially as set forth.

10. The combination of a rotary core, a cylinder surrounding the core and contacting therewith at one side to form an abutment, pistons carried by said core, cams secured to the heads of said cylinder for holding the pistons in contact with the inner surface of the cylinder, and plates secured to the ends of said core and located between said cams and the heads of the cylinder, packing-rings between the heads of the cylinder and said end plates, packing-rings between the ends of said core and the inner sides of said cams, and means for admitting and exhausting fluid to and from the cylinder, substantially as set forth.

810,602. BORING-TOOL. CHARLES BAAR, Grand Rapids, Mich. Filed Feb. 6, 1905. Serial No. 244,495.

Claim.—1. A boring-tool comprising a head having a socket in its axis and also having tangential slots at opposite sides of the socket and extending transversely through the head, a bit inserted in the socket, cutters in the slots, and a binding-screw extending transversely through the head and cutters.

2. A boring-tool comprising a head having an axial socket at one end, and a shank at the other end, and also having upwardly-diverging tangential slots at opposite sides of the socket and extending transversely through the head, a bit inserted in the socket, cutters inserted in the slots, and a binding-screw extending through the axis of the head and through openings in the cutters.

3. A boring-tool comprising a head having a socket in its axis and also having tangential slots at opposite sides of the socket and extending transversely through the head, a bit inserted in the socket, cutters having both end and side cutting edges and inserted in the slots, and a binding-screw extending transversely through the head and cutters.

4. A boring-tool comprising a cylindrical head having an axial socket at one end and a shank at the other end, and also having upwardly-diverging tangential slots at opposite sides of the socket, a bit in the socket, cutters in the slots and provided with internal openings, and a screw extending through the head and cutters.

5. A boring-tool comprising a head having transverse tangential slots extending therethrough, cutters inserted in said slots and a binding-screw extending through the head and cutters, whereby the cutters are clamped in the slots.

6. A boring-tool, comprising a head having transverse upwardly-diverging slots at opposite sides of its axis, cutters inserted in said slots, and a binding-screw extending transversely through the axis of the head and through the cutters.

7. A boring-tool comprising an integral head having transverse upwardly-diverging slots therethrough, cutters inserted in the slots and having both end and side cutting edges, and a clamping-bolt extending transversely through the axis of the head and through the cutters.

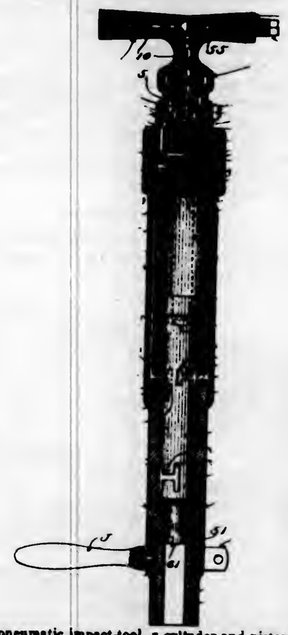
810,603. PNEUMATIC TOOL. WILLIAM B. BADGER, Quincy, Mass. Filed July 20, 1904. Serial No. 217,304.

Claim.—1. In a pneumatic impact-tool, a cylinder and piston, a valve-casing having a valve therein for controlling the movements of the piston, a head secured to said cylinder and held in fixed relation thereto and to said valve-casing, a handle or support upon which said head is rotatably mounted and means to rotate said cylinder.

2. In a pneumatic impact-tool, a cylinder and piston, a valve-casing having a valve therein for controlling the movements of the piston, a head secured to said cylinder and held in fixed relation thereto and to said valve-casing, a handle or support upon which said head is rotatably mounted and longitudinally movable with relation thereto and means to rotate said cylinder.

3. In a pneumatic impact-tool, a cylinder and piston, a valve-casing having a valve therein for controlling the movements of the

piston, a head secured to said cylinder and held in fixed relation thereto and to said valve-casing, a handle or support upon which said head is rotatably mounted, a passage in said handle which may be connected with a source of fluid-pressure supply, means to control the admission of fluid to said valve-casing, and means to rotate said cylinder.



4. In a pneumatic impact-tool, a cylinder and piston, a valve-casing having a valve therein for controlling the movements of the piston, a head secured to said cylinder and held in fixed relation thereto and to said valve-casing, a handle or support upon which said head is rotatably mounted, said head having a passage for motive fluid which is alternately placed in communication with opposite ends of the cylinder, a passage in said handle which may be connected with a source of fluid-pressure supply and is adapted to be placed in communication with said passage in the head, and means to rotate said cylinder with relation to said handle and source of fluid-pressure supply.

5. A pneumatic impact-tool, having a cylinder provided with a head, a grasping-handle having a projecting stem longitudinally movably mounted in the head, said head having a passage communicating with the interior of the cylinder and a passage through said handle and stem which may be connected with a source of fluid-pressure supply and is adapted to communicate with the passage in the head, means whereby said cylinder may be rotated with relation to said grasping-handle, and means whereby the motive fluid may be supplied to the cylinder through said passages when the handle is in its forward position and the cylinder is rotated with relation to said grasping-handle and source of fluid-pressure supply.

6. A pneumatic impact-tool having a cylinder provided with a head adapted to receive the stem of a grasping-handle, and having a passage communicating with the interior of the cylinder, a grasping-handle having a stem longitudinally movably mounted in said head, a passage therein which may be connected with a source of fluid-pressure supply, said passage leading to an outlet in the stem which is adapted to communicate with the passage in the head, means whereby the cylinder may be rotated with relation to said grasping-handle, and means whereby the motive fluid will be supplied to the cylinder through said passages when the handle is in its forward position and the cylinder is rotated with relation to said grasping-handle and source of fluid-pressure supply.

7. A pneumatic impact-tool having a cylinder provided with a head adapted to receive the stem of a grasping-handle, and having a passage communicating with the interior of the cylinder, a grasping-handle provided with a stem, a passage in said handle and stem which may be connected with a source of fluid-pressure supply, said passage leading to an outlet in the stem, said stem being rotatably mounted and longitudinally movable in the head, means whereby the cylinder may be rotated with relation to the grasping-handle, means whereby the motive fluid may be supplied to the cylinder through said passages when the handle is in its forward position and the cylinder is rotated with relation to the grasping-handle and source of fluid-pressure supply, and means whereby said stem is retained in the head.

8. A pneumatic impact-tool having a cylinder provided with a head held in fixed relation thereto and having a passage communicating with the interior of the cylinder, a grasping-handle provided with a stem projecting forwardly at an angle thereto and rotatably mounted in the head, a passage in said handle and stem which may be connected with a source of fluid-pressure supply, said passage leading to an outlet in said stem, means to rotate said cylinder and head, and means whereby said outlet in the stem may be maintained in communication with said passage in the head when the latter is rotated with relation to said grasping-handle and stem.

9. A pneumatic impact-tool having a cylinder provided with a head held in fixed relation thereto and having a passage communicating with the interior of the cylinder, a handle having a stem rotatably mounted in the head and a passage therein for the motive fluid, said handle having a passage therein which may be connected with a source of fluid-pressure supply, said passage being connected with an outlet in said stem, means to rotate said cylinder and head, means whereby said outlet in the stem may be brought in communication with said passage in the head to furnish a supply of motive fluid thereto when the tool is in operation and when the cylinder and head are rotated with relation to the grasping-handle.

10. A pneumatic impact-tool having a cylinder provided with a head adapted to receive the stem of a grasping-handle, and having a passage communicating with the interior of the cylinder, a handle having a stem and a grasping portion projecting at an angle from said stem, a passage in the stem and grasping portion of the handle which may be connected with a source of fluid-pressure supply, said passage leading to an outlet in the stem, said stem being rotatably mounted and longitudinally movable in the head, means for retaining the stem in the head, means whereby the cylinder may be rotated with relation to the handle and means whereby the motive fluid may be supplied to the cylinder through said passages when said handle is in its forward position and the cylinder is so rotated with relation to said handle and source of fluid-pressure supply.

11. A pneumatic impact-tool having a cylinder provided with a head adapted to receive the stem of a grasping-handle, and having a passage communicating with the interior of the cylinder, a grasping-handle having a stem longitudinally and rotatably mounted in the head, said handle and stem having a passage which may be connected with a source of fluid-pressure supply and is adapted to communicate with the passage in the head, means whereby the cylinder may be rotated with relation to the grasping-handle, and means whereby the motive fluid may be supplied to the cylinder through said passages when the handle is in its forward position and the cylinder is so rotated with relation to said handle and source of fluid-pressure supply.

12. A pneumatic impact-tool having a cylinder provided with a head adapted to receive the stem of a grasping-handle, and having a passage communicating with the interior of the cylinder, a grasping-handle having a stem longitudinally and rotatably mounted in the head, means for retaining said stem in the head, said handle and stem having a passage which may be connected with a source of fluid-pressure supply and is adapted to communicate with the passage in the head, means whereby the cylinder may be rotated with relation to the grasping-handle, and means whereby the motive fluid may be supplied to the cylinder through said passages when the handle is in its forward position and the cylinder is so rotated with relation to said handle and source of fluid-pressure supply.

13. A pneumatic impact-tool having a cylinder provided with a head adapted to receive the stem of a grasping-handle, and having a passage communicating with the interior of the cylinder, a grasping-handle having a stem longitudinally and rotatably mounted in the head, means for retaining said stem in the head, said handle and stem having a passage which may be connected with a source of fluid-pressure supply and is adapted to communicate with the passage in the head, when the handle and stem are in a forward position, means whereby the cylinder may be rotated with relation to the grasping-handle, and means whereby the motive fluid may be supplied to the cylinder through said passages when the cylinder is so rotated with relation to said handle and source of fluid-pressure supply.

14. A piston impact-tool having a cylinder and a grasping-han-

die provided with a projecting stem mounted rotatably and longitudinally to said cylinder, a passage in the handle and stem which may be connected with a source of fluid-pressure supply, means to control the admission of motive fluid to the interior of the cylinder, a handle secured to the cylinder for rotating the latter, and means whereby the motive fluid may be supplied to the cylinder through said passage when said grasping-handle is in its forward position and the cylinder is rotated with relation to the grasping-handle and source of pressure-supply.

15. A pneumatic impact-tool having a cylinder provided with a head, a passage therein communicating with the interior of the cylinder, a grasping-handle provided with a stem longitudinally and rotatably mounted in the head, a passage in the handle and stem which may be connected with a source of fluid-pressure supply and is adapted to communicate with the passage in the head when the handle is in a forward position, a handle secured to the cylinder for rotating the latter, and means whereby the motive fluid may be supplied to the cylinder through said passages when said grasping-handle is in its forward position and the cylinder is rotated with relation to the grasping-handle and the source of fluid-pressure supply.

16. A pneumatic impact-tool having a cylinder provided with a head, a passage therein communicating with the interior of the cylinder, a grasping-handle provided with a stem longitudinally and rotatably mounted in the head, a passage in the handle and stem which may be connected with a source of fluid-pressure supply and is adapted to communicate with the passage in the head, said cylinder being provided with a forward head secured thereto and having a socket therein adapted to engage the shank of a working tool, a handle secured to the cylinder for rotating the latter and said working tool, and means whereby the motive fluid may be supplied to the cylinder through said passages when the said grasping-handle is in its forward position and the cylinder is rotated with relation to said grasping-handle and source of fluid-pressure supply.

17. A pneumatic impact-tool having a cylinder containing a piston, a valve for controlling the motive fluid within said tool, a valve-casing located within the rear of the piston-chamber, a head and a handle having a pressure-supply passage therethrough leading to the valve-casing, said head being rotatably mounted on said handle, means for holding said head in a fixed relation to the cylinder, and means for rotating said cylinder and head with relation to said handle.

18. An impact-tool having a cylinder provided with a head secured in fixed relation thereto, a handle or support on which said head is rotatably mounted, a passage in said handle which may be connected with a source of fluid-pressure supply, a passage in said head to which the motive fluid is supplied by said passage in the handle when the tool is in operation, and means to rotate said cylinder and head with relation to said handle.

19. An impact-tool having a cylinder provided with a head secured in a fixed relation thereto, a handle or support on which said head is rotatably mounted, a passage in said handle which may be connected with a source of fluid-pressure supply, a passage in said head to which the motive fluid is supplied by said passage in the handle when the tool is in operation, means to rotate said cylinder with relation to said handle and a forward head to the cylinder adapted to engage the shank of a working tool to rotate the latter.

20. An impact-tool having a cylinder provided with a head secured in fixed relation thereto, a handle or support on which said head is rotatably mounted, a passage in said handle which may be connected with a source of fluid-pressure supply, a passage in said head to which the motive fluid is supplied by said passage in the handle when the tool is in operation, means to rotate said cylinder and head with relation to said handle and means whereby the motive fluid will be supplied through said passage in the handle to said passage in the head when the latter is rotated with relation to said handle.

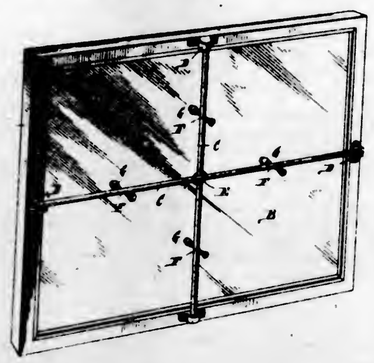
21. An impact-tool having a cylinder provided with a head secured in fixed relation thereto, a valve-block having a valve therein for controlling the movements of the piston, a handle or support on which said head is rotatably mounted, a passage in said handle which may be connected with a source of fluid-pressure supply, a passage in said head through which the motive fluid may be supplied from said passage in the handle to the valve-block and means to rotate said cylinder and head with relation to said handle.

22. An impact-tool having a cylinder provided with a head secured in fixed relation thereto, a valve-block having a valve therein for controlling the movements of the piston, a handle or support on which said head is rotatably mounted, a passage in said handle which may be connected with a source of fluid-pressure supply, a passage in said head through which the motive fluid may be supplied from said passage in the handle to the valve-block, means to rotate said cylinder and head, and means whereby the motive fluid may be supplied through said passage in the handle to said passage in the head when the latter is rotated with relation to said handle.

23. An impact-tool having a cylinder provided with a head secured in fixed relation thereto, a handle or support on which said head is rotatably and longitudinally mounted, a passage in said handle which may be connected with a source of fluid-pressure, a passage in said head to which the motive fluid is supplied from said passage in the handle, when the latter is in its forward position and the cylinder and head are rotated with relation to said handle.

24. A pneumatic impact-tool having a grasping-handle with an air-passage therethrough, a cylinder, a cylinder-head to receive said handle and formed with an air-passage adapted to communicate with an outlet from the passage in the handle, said handle having a stem which fits into the interior of the head and having an annular flange which fits outside of said head, thereby forming an annular grooved bearing for the rear end of the head.

810,604. PROTECTOR FOR WINDOWS. GEORGE BAIER, Buffalo, N. Y., assignor of one-half to George Baier, Jr., Buffalo, N. Y. Filed Apr. 10, 1905. Serial No. 254,841.



Claim.—1. In a window-protector, the combination of a support, and a pressure member bearing against the window and adjustable on said support.

2. In a window-protector, the combination of a support, and pressure members carried by said support and disposed at an angle thereto, said pressure members having yielding pressure ends bearing against the window.

3. In a window-protector, the combination of a support, and a pressure member carried by said support and disposed at a right angle to the latter to bear against the window.

4. In a window-protector, the combination of a support having a threaded aperture, a pressure member adjustable in said aperture and bearing against the window.

5. In a window-protector, the combination of a support, a pressure member carried by said support and comprising a threaded shank adjustable toward and from the window, and a pressure-piece at the end of said shank to bear against the window.

6. In a window-protector, the combination with a window and a window-frame, of a supporting-bar having its ends secured to said frame, and pressure members carried by said bar and adjustable thereon

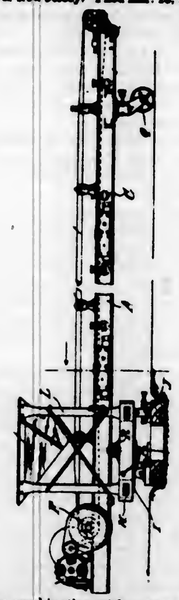
7. In a window-protector, the combination with a window and a window-frame, of a supporting-bar having its ends secured to said frame and provided with threaded apertures, and pressure members adjustable in said apertures and adapted to bear against the window.

8. In a window-protector, the combination with a window and a window-frame, of a supporting-bar having its ends secured to said frame and provided with transverse threaded apertures, and pressure members comprising each a threaded shank passing through one of said apertures and a yielding pressure-piece at the end of said shank in contact with the window.

9. In a window-protector, the combination with a window and a window-frame, of a supporting-bar having its ends secured to said frame and provided with transverse threaded apertures, and pressure members comprising each a threaded shank passing through one of said apertures, a socket in which the inner end of said shank is revolubly held, and a yielding plug secured within said socket and extending therefrom to bear against the window.

10. In a window-protector, the combination with a window and a window-frame, of two supporting-bars crossing each other and secured at their ends to the window-frame, a connection for said bars at their point of crossing, and pressure-pieces carried by said bars and adjustable toward and from the window.

810,605. CONVEYER. CLARENCE K. BALDWIN and THOMAS ROBINS, Jr., New York, N. Y., assignors to The Robins Conveying Belt Co., a Corporation of New Jersey. Filed Mar. 18, 1903. Serial No. 148,360.



Claim.—1. The combination with a support, of a conveyer and conveyer-frame mounted to travel thereon, and having the delivery end of the conveyer both vertically and horizontally movable, and an engine or motor for operating the conveyer mounted upon the conveyer-frame, for substantially the purposes set forth.

2. The combination with a support, of a conveyer and conveyer-frame mounted to travel thereon, and having the delivery end of the conveyer movable in all directions in a horizontal plane, and an engine or motor for operating the conveyer mounted upon the conveyer-frame, for substantially the purposes set forth.

3. The combination with a turn-table, of a conveyer and conveyer-frame mounted for pivotal movement in relation to the turn-table, said conveyer and frame being capable of bodily travel also in a horizontal plane only over said table and transversely to the vertical axis thereof, for substantially the purposes set forth.

4. The combination with a turn-table, of a conveyer and conveyer-frame pivotally mounted relatively to the table, said conveyer and frame also being slidable transversely across the table, for substantially the purposes set forth.

5. The combination with a turn-table, of a hopper, a conveyer and conveyer-frame pivotally and slidably mounted relatively to the turn-table and hopper, for substantially the purposes set forth.

6. The combination with the turn-table, of a hopper, a conveyer and conveyer-frame pivotally and slidably mounted relatively to the turn-table and hopper, and an engine or motor for operating the conveyer mounted upon the conveyer-frame, for substantially the purposes set forth.

7. The combination with a continuously-traveling belt, of a hopper and a shaking feeder-chute, one end of which chute moves in substantially a horizontal plane, whereby the relative distance between the end of the chute and the traveling belt remains practically constant and injury to the belt is avoided, and means for reciprocating said chute, for substantially the purposes set forth.

8. The combination with a continuously-traveling belt, of a hopper and feeder-chute, said chute being suspended to swing at one end and provided with rollers at the other end, a horizontal track for said rollers, and means for imparting a reciprocating motion to the said chute to feed the material to the belt, for substantially the purposes set forth.

9. The combination with a continuously-traveling belt, of a hopper and a shaking feeder-chute, one end of which is mounted to swing, and the other end of which is movable in substantially a horizontal plane, and means for preventing the chute from swinging sidewise, whereby injury to the belt is prevented, and means for imparting a reciprocating motion to the chute, for substantially the purposes set forth.

10. The combination with a continuously-traveling belt, of a hopper and a feeder-chute, one end of which is mounted to swing, and the other end of which is mounted to move in substantially a horizontal plane, means for reciprocating said chute, and means for adjusting the angle of the chute, and means for varying the throw, for substantially the purposes set forth.

11. In a conveyer, the combination with a vertically-adjustable main frame, of a jointed section pivotally connected thereto, a conveyer carried by both said frames, and an engine or motor for operating the conveyer mounted upon said pivotally-connected section of the frame, for substantially the purposes set forth.

12. The combination with a shaking feeder-chute, of a swinging hanger therefor, and a substantially smooth track upon which the delivering end of the chute is supported and upon which the chute may be given a reciprocatory movement, for substantially the purposes set forth.

13. The combination with a shaking feeder-chute, of a swinging hanger near the receiving end of the chute, and a substantially smooth track upon which the delivering end of the chute is supported and upon which it is susceptible of reciprocatory movement, for substantially the purposes set forth.

14. The combination with a shaking feeder-chute, having its delivering end supported for reciprocatory movement in a horizontal plane, of a swinging support for the receiving end of the chute, and means for reciprocating the chute, for substantially the purposes set forth.

15. The combination with a shaking feeder-chute, of a conveyer to which said chute is adapted to deliver material, a swinging hanger for said chute, and supporting devices for the delivering end of said chute which permit the chute to be given a reciprocatory movement in a plane substantially parallel to the conveyer, for substantially the purposes set forth.

16. The combination with a conveyer, of a shaking feeder-chute, a swinging support for the receiving end of the chute, a track substantially parallel with said conveyer upon which the delivering end of said chute is supported, and means for reciprocating the delivering end of said chute for substantially the purposes set forth.

17. The combination with a shaking feeder-chute, of swinging suspension devices for the receiving end of said chute, a substantially smooth track upon which the delivering end of said chute is supported, and means for reciprocating the delivering end of said chute along said track, said means being susceptible of adjustment to vary the throw of the chute, for substantially the purposes set forth.

18. The combination with a shaking feeder-chute set on an incline, of swinging suspension devices for the receiving end of said chute which are adjustable in length, and a substantially smooth track upon which the delivering end of said chute is supported and upon which it may be given a reciprocatory movement, for substantially the purposes set forth.

19. The combination with an inclined feeder-chute, of means for imparting oscillatory movement to its upper end, and means for imparting reciprocatory movement to its lower end.

810,606. MUSIC-ROLL AND ADJUSTABLE DRIVING-SUPPORT THEREFOR. HENRY P. BALL, Schenectady, N. Y., assignor of one-half to Samuel Insull, Chicago, Ill. Filed Oct. 26, 1903. Serial No. 178,503.

Claim.—1. A music-roll comprising a tubular body portion, flange portions secured to said body portion, and a music-strip portion wound upon said body portion, said body portion and music-strip portion having the same coefficient of expansion and contraction, in combination with a spindle having a hinged joint and forming a part of a mechanical musical instrument, and over which said body and music-strip portions may be placed and by which they may be driven.

2. A music-roll comprising a body portion, flange portions, and

a music-strip portion, in combination with a spindle hinged at one end to and forming a part of a mechanical musical instrument, together with means for securing said music-roll in position upon said spindle.

3. A music-roll comprising a body portion, flange portions and a music-strip portion, in combination with a spindle forming a part of a mechanical musical instrument, said spindle hinged at one end and coacting at the other end with driving means.

4. A music-roll comprising a tubular body portion, flange portions and a strip portion, in combination with a spindle forming a part of a mechanical musical instrument and adapted to enter said tubular portion, said spindle hinged at one end in a resilient bearing, and coacting at the opposite end with the roll-driving head of a mechanical musical instrument.

5. A music-roll comprising a body portion and a strip portion, in combination with a spindle forming a part of a mechanical musical instrument, and mounted at one end in a ball-and-socket joint carried by a resilient bearing, and provided at its other end with means for connecting said spindle with the usual roll-driving head of a mechanical musical instrument.

6. A music-roll comprising a tubular body portion, flange portions, and a music-strip portion, in combination with a spindle, a bearing for one end of the spindle permanently connected to a mechanical musical instrument and adapted to permit the opposite end of the spindle to be moved in a circular direction around the point of attachment of the bearing, together with means for driving said spindle.

7. In a mechanical musical instrument, a roll-spindle secured at one end of said instrument by a universal joint, and detachably connected at its other end with the usual roll-driving head of the instrument.

8. In a mechanical musical instrument, a spindle secured at one end to said instrument through a ball-and-socket joint mounted in a resilient sleeve, and at the other end through a device coacting with the usual roll-driving head of said instrument.

9. In a mechanical musical instrument, a spindle secured at one end to said instrument through a ball-and-socket joint mounted in a resilient sleeve, and at the other end through a device coacting with the usual roll-driving head of said instrument, together with a separable music-roll on said spindle having its body portion tubular, with flanges at the ends and carrying a perforated music-strip.

10. In a mechanical musical instrument, a spindle having two diameters, and connected at one end to said instrument through a universal joint, and detachably connected at its other end to said instrument through a flange-joint.

11. In combination in a mechanical musical instrument, a driving-spindle having two diameters and connected at one end to said instrument through a universal joint, means for driving said spindle, a music-roll adapted to coact with said spindle, and means on the spindle whereby the music-roll will be rotated when the spindle is rotated.

12. In combination in a mechanical musical instrument, a spindle attached at one end to said instrument through a universal joint, a longitudinally-movable bearing for said joint, a removable music-roll mounted on said spindle, means for securing said music-roll on said spindle, and means for driving said spindle.

13. In combination in a mechanical musical instrument, a driving-spindle connected at one end to said instrument through a universal joint, a longitudinally-movable bearing for said joint, said spindle of greater diameter at one end than at the other, a detachable music-roll on said spindle, a ring secured to the interior of the music-roll, a spring device mounted upon the spindle for effecting engagement between the spindle and the music-roll, and means for driving the music-roll.

14. In a mechanical musical instrument, a supporting-spindle for the music-roll universally mounted at one end in a longitudinally-movable bearing, a driver for the spindle, and means for connecting the spindle to the driver.

15. In a mechanical musical instrument, a spindle having a ball-and-socket joint at one end, a driver therefor coacting with the opposite end of the spindle, and detachable means for detaching the spindle from the driver.

16. In a mechanical musical instrument, a spindle hinged at one end to the instrument, a driving means for the spindle, and detachable means for connecting said spindle to the driving means.

17. In a mechanical musical instrument, a spindle hinged to a longitudinally-movable bearing supported in the instrument, a driving means for the spindle, and detachable means for connecting said spindle with the driving means.

18. In combination in a mechanical musical instrument, a music-roll having a tubular body, a structurally-independent spindle hinged to the instrument, a driver for the spindle, and means for detaching the spindle from the driver.

19. In combination in a mechanical musical instrument, a music-roll comprising a body portion, flange portions, and a strip portion, a hinged spindle, a driver for the same, and detachable means for connecting said spindle with the driver.

20. In combination in a mechanical musical instrument a music-roll having a tubular body, a structurally-independent spindle, and means introduced between the two which will act to automatically center the music-roll longitudinally on the spindle and irrespective of the length of the music-roll.

21. In combination in a mechanical musical instrument, a perforated strip, a tubular body on which said strip is wound, a stop device inside of the tubular body, and a spindle carrying a device for engaging said stop device.

22. In a mechanical musical instrument, a music-roll having a hollow body and a clutch member at its center, in combination with a structurally-independent spindle passing through the body, and a resilient catch engaging the spindle with the body.

23. In a mechanical musical instrument, a music-roll having a hollow body of hygroscopic material and a clutch member at its center, in combination with a structurally-independent spindle passing through the body, and a clutch member on the spindle engaging with the first-named clutch member.

24. In a mechanical musical instrument, a music-roll having a hollow paper body and a clutch member at its center, and a structurally-independent spindle passing through the body engaging with the clutch member, and means for driving the music-roll by the spindle.

25. In a mechanical musical instrument, a music-roll having a hollow body, a flange at each end thereon, and a clutch member at its center, in combination with a structurally-independent spindle passing through the body, and a clutch member thereon locating the body longitudinally on the spindle in one position.

26. In a mechanical musical instrument a music-roll having a hollow body, a structurally-independent spindle, and a clutching device situated between the two members and adapted, irrespective of the length of the music-roll, to secure said two members together at their centers, leaving the ends thereof free.

27. In a mechanical musical instrument a music-roll having a hollow body formed of hygroscopic material, a structurally-independent supporting spindle, a clutching device situated between the two members, said clutching device comprising a ring situated on the interior and at the center of the hollow body, and a spring device mounted on the surface and at the center of the spindle and adapted to center the music-roll on the spindle and irrespective of the length of the music-roll.

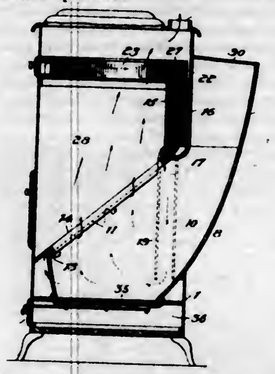
28. In a mechanical musical instrument the combination of a music-roll, an independent supporting-spindle, a clutching device situated between the center of the music-roll and the center of the spindle and adapted to hold the music-roll in a central position on the spindle and irrespective of its length.

29. In a mechanical musical instrument, a roll-spindle having a clutch device for detachably securing the roll in one position thereon, and means for transmitting motion from the spindle to the roll.

30. In a mechanical musical instrument, the combination of a music-roll comprising a hollow supporting-body, flanges at the end of said body, a slotted plate in one of said flanges, a separate supporting-spindle provided with keys at one end, which coact with the slots in the slotted plate, and means situated partially on the interior of the body at its center and partially on the exterior of the spindle at its center and adapted to coact to define the position of the body upon the spindle.

810,607. HEATER. ARCHIE W. BANKS, Rockford, Ill., assignor of one-fifth to Martin A. Banks, Rockford, Ill. Filed Feb. 29, 1904. Serial No. 196,946.

Claim.—1. In a heater, an outer casing, a fire-pot located within the casing leaving an air-conduit around the fire-pot, a deflecting-plate located over the upper edge of the fire-pot leaving air-passages between the plate and fire-pot, two vertical partitions at the sides of the fire-pot stopping short of the bottom of the fire-pot, and a vertical air passage-way at the back of the heater communicating with the conduit between the partitions.



2. In a heater, an outer casing, a fire-pot located within the casing leaving an air-conduit around the fire-pot, a deflecting-plate located over the upper edge of the fire-pot leaving air-passages between the plate and fire-pot, two vertical partitions at the sides of the fire-pot stopping short of the bottom of the fire-pot, a vertical air passage-way at the back of the heater communicating with the conduit between the partitions, and a top formed with an annular passage-way having a communication with the vertical passage-way and with the outer air.

3. In a heater, an outer casing, a fire-pot located within the casing leaving an air-conduit around the fire-pot, a deflecting-plate located over the upper edge of the fire-pot leaving air-passages between the plate and fire-pot, two vertical partitions at the sides of the fire-pot stopping short of the bottom of the fire-pot, a vertical air passage-way at the back of the heater communicating with the conduit between the partitions, and a top formed with an annular passage-way having a communication with the vertical passage-way and with the outer air, the fire-pot having a fuel-magazine at its rear and separated from the combustion-chamber by the vertical air passage-way.

810,608. WEB-PERFECTING PRINTING-PRESS. ENGLAND J. BARNES, Morgan Park, Ill. Filed Apr. 24, 1903. Renewed Apr. 24, 1905. Serial No. 257,695.

Claim.—1. In a web-perfecting printing-press, the combination with an impression-cylinder, of a type-cylinder and a numbering device, each capable of a planetary adjustment around the circumference of said impression-cylinder, said type-cylinder being movable longitudinally of its shaft.

2. In a web-perfecting printing-press, the combination with an impression-cylinder, of a type-cylinder and a numbering device, each capable of a planetary adjustment independently of each other, around the circumference of said impression-cylinder, said type-cylinder being movable longitudinally of its shaft.

3. In a web-perfecting printing-press, the combination with an impression-cylinder, of a type-cylinder and a revolving numbering device, each capable of a planetary adjustment independently of each other around the circumference of said impression-cylinder, said type-cylinder being movable longitudinally of its shaft.

4. In a web-perfecting printing-press the combination with an impression-cylinder, of a type-cylinder capable of a planetary adjustment around the circumference of said impression-cylinder and having a limited radial adjustment to and from the same, said type-cylinder being movable longitudinally of its shaft.

5. In a web-perfecting printing-press the combination with an impression-cylinder, of a type-cylinder, and a revolving numbering device, each capable of a planetary adjustment independent of each other and having a limited radial adjustment to and from said cylinder, said type-cylinder being movable longitudinally of its shaft.

6. In a web-perfecting printing-press, the combination, with an impression-cylinder, and means for guiding the web of paper through the press, of revolving punches having a planetary adjustment around said impression-cylinder, and operating on said paper independently of said cylinder.

7. In a web-perfecting printing-press the combination with an impression-cylinder, and means for guiding the web of paper through the press, of revolving punches and a type-cylinder, both of which are adjustable independently of each other.

8. In a web-perfecting printing-press the combination with an impression-cylinder, of a frame adjustable concentric to said cylinder, and means for guiding the web of paper therethrough and revolving punches said guiding means and punches being carried by said frame.

9. In a web-perfecting printing-press the combination with an impression-cylinder, of a frame adjustable concentric to said cylinder, and means for guiding the web of paper therethrough, and longitudinally-adjustable revolving punches said guiding means and punches being carried by said frame.

10. In a web-perfecting printing-press the combination with an impression-cylinder, of a frame adjustable concentric to said cylinder, and means for guiding the web of paper therethrough and revolving punches said guiding means and punches being carried by said frame and deriving motion from the shaft of said impression-cylinder.

11. In a web-perfecting press the combination with an impression-cylinder, of a frame adjustable concentric to said cylinder, means for guiding the web of paper therethrough, revolving punches and means for slitting said paper longitudinally all of which are carried by said frame.

12. In a web-perfecting press the combination with an impression-cylinder, of a frame adjustable concentric to said cylinder, means for guiding the web of paper therethrough, revolving punches and revolving cutters for slitting said paper longitudinally, all of which are carried by said frame.

13. In a web-perfecting printing-press the combination with an impression-cylinder, of a frame adjustable concentric to said cylinder, means for guiding the web of paper therethrough, revolving punches, a pair of revolving cutters for slitting said paper longitudinally the axis of one of which is movable to and from the axis of the other, all of which are carried by said frame.

14. In a web-perfecting printing-press the combination with an impression-cylinder, of a frame adjustable concentric to said cylinder, means for guiding the web of paper therethrough, revolving punches, two revolving shafts, a revolving cutter on one of said shafts, an arm projecting from the other shaft and a revolving cutter journaled in the free end thereof, and adjustable to and from the other cutter, all of which are carried by said frame.

15. In a web-perfecting printing-press, the combination with an impression-cylinder, of a frame adjustable concentric to said cylinder, means for guiding the web of paper therethrough, two revolving shafts one of which is stationary and the other flexible a revolving cutter on said stationary shaft, an arm projecting from said flexible shaft, and a revolving cutter journaled in the free end thereof, and adjustable to and from the other cutter, all of which are carried by said frame.

16. In a web-perfecting printing-press the combination with an impression-cylinder, of a frame adjustable concentric to said cylinder comprising two side frames suitably connected together beyond the circumference of the cylinder and journaled concentric to the cylinder adjacent to the ends thereof, and one of said frames

having a segmental gear extending therefrom, a pinion engaging said segmental gear, and devices carried by said frame cooperating with said cylinder.

17. In a web-perfecting printing-press, the combination with an impression-cylinder, of several independent frames each adjustable concentric to said cylinder, a printing-cylinder carried by one of said frames, a numbering device carried by another of said frames, and punching device carried by yet another of said frames.

18. In a web-perfecting printing-press, the combination with an impression-cylinder, of several independent frames each adjustable concentric to said cylinder, a printing-cylinder carried by one of said frames, a multiple numbering device carried by another of said frames and a punching device carried by yet another of said frames.

19. In a web-perfecting printing-press, the combination with an impression-cylinder, of several independent frames each adjustable concentric to said cylinder, a printing-cylinder carried by one of said frames, a revolving numbering device carried by another of said frames, and revolving punching device carried by yet another of said frames.

20. In a web-perfecting printing-press, the combination with an impression-cylinder, of a printing-cylinder, numbering mechanism and punching devices, adjustable in curved paths struck from the center of the impression-cylinder to and from each other.

21. In a web-perfecting printing-press, the combination with an impression-cylinder and the supporting-frame therefor having bearings for the shaft of said cylinder, the outer cylindrical ends of which are extended, of a frame adjustable concentric to said cylinder on the extensions of said bearings, devices carried by said frame cooperating with said cylinder, and means for adjusting said frame.

22. In a web-perfecting printing-press, the combination with an impression-cylinder and the supporting-frame therefor having bearings for the shaft of said cylinder, the outer cylindrical ends of which are extended, of several frames independently adjustable concentric to said cylinder on the extensions of said bearings devices carried by said frames coöperating with said cylinder, and means for adjusting said frame.

23. In a web-perfecting printing-press, the combination with an impression-cylinder and the supporting-frame therefor having bearings for the shaft of said cylinder, the outer cylindrical ends of which are extended, of a frame adjustable concentric to said bearings, and having a segmental gear projecting therefrom, pinion engaging said segmental gear, devices carried by said frame coöperating with said cylinder, and means for adjusting said frame.

24. In a web-perfecting printing-press, the combination with an impression-cylinder and the supporting-frame therefor having bearings for the shaft of said cylinder, the outer cylindrical ends of which are extended, of several frames independently adjustable concentric to said cylinder on the extensions of said bearings and having a segmental gear projecting therefrom, pinion engaging said segmental gear, devices carried by said frames coöperating with said cylinder, and means for adjusting said frame.

25. In a web-perfecting printing-press, the combination with the impression-cylinder, of a frame adjustable concentric to said cylinder, a revolving printing device, shaft therefor having spring-depressed removable bearings in said frame, and eccentric-pins for adjusting said bearings to and from said impression-cylinder.

26. In a web-perfecting printing-press, the combination with the impression-cylinder, of frames adjustable concentric to said cylinder, revolving printing devices, shafts therefor respectively having spring-depressed removable bearings in said frames, eccentric-pins for adjusting said bearings to and from said impression-cylinder and means for connecting pins in the several frames, whereby they operate simultaneously.

27. In a web-perfecting printing-press, the combination with the impression-cylinder, of a frame adjustable concentric to said cylinder, an ink-fountain carried thereby comprising a suitable receptacle a roller forming part of its bottom by means of which alone ink is mechanically taken from said fountain, a revolving printing device, shaft therefor, deriving motion from said impression-cylinder, an inking-roller in constant engagement with said printing device, and means for transferring said ink from said fountain to said ink-roller, all of which are carried by said frame.

28. In a web-perfecting printing-press, the combination with the impression-cylinder, of a frame adjustable concentric to said cylinder, an ink-fountain carried thereby comprising a suitable receptacle a roller forming part of its bottom by means of which alone, ink is mechanically taken from said fountain, a revolving printing device, a shaft therefor, deriving motion from said impression-cylinder, an inking-roller in constant engagement with said printing device, an oscillatory ink-roller for transferring to said constantly-engaging ink-roller, all of which are carried by said frame.

29. In a web-perfecting printing-press, the combination with the impression-cylinder, of a frame adjustable concentric to said cylinder, an ink-fountain carried thereby comprising a suitable receptacle a roller forming part of its bottom by means of which alone, ink is mechanically taken from said fountain, a revolving printing device, a shaft therefor, deriving motion from said impression-cylinder, an inking-roller in constant engagement with said printing device, a cam-actuated oscillatory ink-roller for transferring to said constantly-engaging ink-roller, all of which are carried by said frame.

30. In a web-perfecting printing-press, the combination with the impression-cylinder, of a frame adjustable concentric to said cylinder, an ink-fountain carried thereby comprising a suitable receptacle a roller forming part of its bottom by means of which alone, ink is mechanically taken from said fountain, a revolving printing device, cam-actuated oscillatory arms, and roller journaled in the free ends thereof whereby said ink is transferred from said fountain to said constantly-engaging ink-roller.

31. In a web-perfecting printing-press, the combination with the impression-cylinder, of a frame adjustable concentric to said cylinder, an ink-fountain, carried thereby comprising a suitable receptacle a roller forming part of its bottom by means of which alone ink is mechanically taken from said fountain, a ratchet on the extended end of one of the journals thereof, a revolving printing device, shaft therefor, deriving motion from said impression-cylinder, an inking-roller in constant engagement with said printing device, cam-actuated oscillatory arms a pawl pivoted to one of said arms and engaging and imparting an intermittent movement to said ratchet, and roller journaled in the free ends of said arms whereby said ink is transferred to said constantly-engaging ink-roller.

32. In a web-perfecting printing-press, the combination with the impression-cylinder, of a frame adjustable concentric to said cylinder, an ink-fountain carried thereby comprising a suitable receptacle a roller forming part of its bottom by means of which alone ink is mechanically taken from said fountain and a longitudinal side wall therefor the lower edge of which bears down upon said roller, a revolving printing device, shaft therefor, deriving motion from said impression-cylinder, an inking-roller in constant engagement with said printing device, and means for transferring said ink-roller, all of which are carried by said frame.

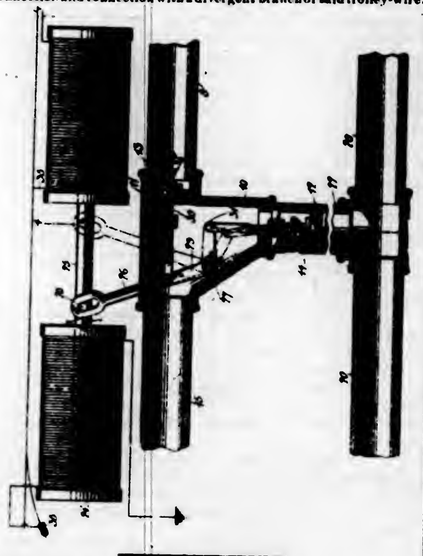
33. In a web-perfecting printing-press the combination with the impression-cylinder, of a frame adjustable concentric to said cylinder, and means carried thereby and coöperating with said impression-cylinder comprising a revolving printing device, a shaft therefor deriving motion from said impression-cylinder, an inking-roller engaging said printing device, a longitudinally-vibrating distributing ink-roller engaging said first-mentioned inking-roller, a cam on the shaft of said distributing-roller, a stationary arm engaging the same, an ink-fountain, and a cam-actuated oscillating ink-roller for transmitting the ink from the ink-fountain to said vibratory roller.

34. In a web-perfecting printing-press, the combination with an impression-cylinder, of a frame adjustable concentrically around said cylinder, a revolving printing device, inking-roller in constant engagement therewith, a vibratory distributing-roller engaging said inking-roller, a cam on the shaft of said distributing-roller, a stationary arm engaging the same, an ink-fountain comprising a suitable receptacle, a roller forming part of its bottom by means of which alone ink is mechanically taken from said fountain, cam-actuated oscillatory arms and a roller journaled in the free ends of the same whereby ink is transferred from said fountain-roller to said distributing-roller.

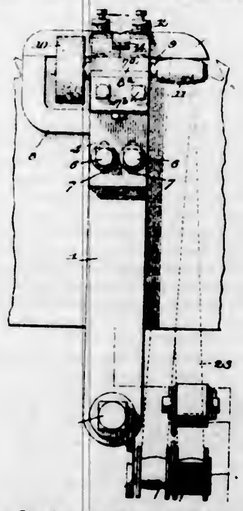
35. In a web-perfecting printing-press, the combination with an impression-cylinder, of a frame adjustable concentrically around said cylinder, a revolving printing device, spring-depressed removable bearings therefor in said frame, an inking-roller in constant engagement therewith, a vibratory distributing-roller engaging said inking-roller, a cam on the shaft of said distributing-roller, a stationary arm engaging the same, an ink-fountain comprising a suitable receptacle, a roller forming part of its bottom by means of which alone ink is mechanically taken from said fountain, cam-actuated oscillatory arms and a roller journaled in the free ends of the same whereby ink is transferred from said fountain-roller to said distributing-roller.

810,609. **ELECTROFLUID PRESSURE MECHANISM FOR OPERATING RAILROAD APPLIANCES.** WALTER J. BELL, Los Angeles, Cal., assignor of one-half to Leon F. Moss, Los Angeles, Cal. Filed Dec. 1, 1902. Serial No. 132,365.

Claim.—In combination with means for supplying fluid under constant pressure and with a railroad appliance operated by compressed fluid, of a compressed-fluid-supply pipe, a fluid-return pipe, a valve at the supply-pipe, a valve at the return-pipe, a connection between said valves to effect their simultaneous movement, an armature operatively connected with said valve connection, a solenoid-magnet slidably receiving said armature and electrically connected with the trolley-wire and an insulated section thereof, and a second solenoid-magnet slidably receiving said armature and having ground connection and connection with a divergent branch of said trolley-wire.



810,610. **SAW-DRESSING MACHINE.** ENERIE L. BISHOP, Waukesee, Wis. Filed Jan. 4, 1905. Serial No. 239,677.



Claim.—1. In a device of the class described, two side members mutually connected by a transverse pivot, shafts supported for rotation near the upper ends of said side members, grinding-disks upon said shafts, means for driving the latter, and means for connecting the upper ends of the side members.

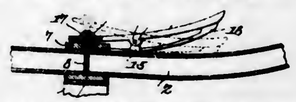
2. In a device for side-dressing saws, a pair of side members connected by a transverse pivot, vertically-adjustable brackets near the upper ends of said side members, laterally-adjustable boxes supported upon said brackets, shafts journaled in the boxes, grinding-disks upon the shafts, driving-pulleys upon said shafts, idlers supported near the lower end of one of the side members, and a driving-belt.

3. A device for side-dressing saws, including a pair of pivotally-connected side members each supporting a driven grinding-disk, and a member connected with said device and adapted to rest upon the points of the saw-teeth to be operated upon to prevent upward displacement of the saw during operation.

4. A device of the class described including pivotally-connected side members adapted to engage the sides of a saw-blade, driven shafts supported adjustably by said side members, grinding-disks supported by said driven shafts, a saw-tooth-engaging device connected with one of the side members, to prevent upward displacement of the saw during operation, and latch means for connecting together the free ends of said side members.

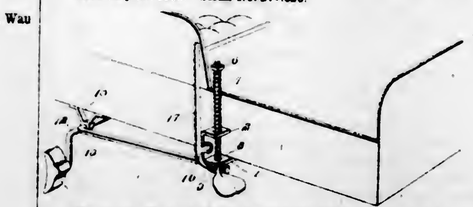
5. A device for side-dressing the teeth of band-saws including a pair of grinding-disks supported to engage the sides of the saw-teeth, and a member engaging the points of the teeth to prevent upward displacement of the saw during operation.

810,611. **DENTAL OBTUNDER.** WESLEY F. BLASINGAME, Moultrie, Ga. Filed Oct. 12, 1905. Serial No. 282,468.



Claim.—An attachment of the class described comprising a sectional water-conducting tube, a valve-casing connecting the sections of the tube and provided with a collar including gripping means, a valve working in the casing and between the opposed ends of the tube-sections, and a spring-pressed lever pivotally connected with one section of the tube and with the valve.

810,612. **VEHICLE-BRAKE.** JOSEPH L. BREWTON, Mill, La. Filed July 28, 1905. Serial No. 271,626.



Claim.—1. The combination with a vehicle-body having a brake movably connected thereto; of a movable step, means actuated thereby for applying the brake when the step is depressed, and means for automatically locking the step when depressed.

2. The combination with a vehicle-body having a brake movably connected thereto; of a resiliently-supported step, means actuated thereby for operating the brake, and means for automatically locking the step when depressed.

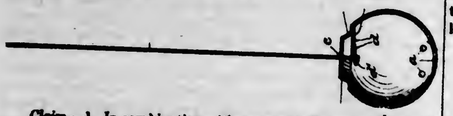
3. The combination with a vehicle-body and a brake movably connected thereto; of a spring-supported step connected to the body, means actuated by the step for operating the brake, and a lock for holding the step against movement.

4. The combination with a vehicle-body and a brake movably connected thereto; of a spring-supported step, means operated thereby for actuating the brake, and a locking device for holding the brake applied when the spring is under tension.

5. The combination with a vehicle-body and a brake movably connected thereto; of a guide secured to the vehicle-body, a spring-supported stem mounted within the guide, a step upon the stem, means actuated by the stem for operating the brake, and a locking device for engaging the stem.

6. The combination with a vehicle-body and a brake movably connected thereto; of a toothed spring-supported stem, a guide therefor connected to the vehicle-body, a step upon the stem, means actuated by the stem for operating the brake, and a lever normally engaging the toothed portion of the stem.

810,613. RETURN-BALL. THOMAS F. BURKE and THOMAS L. VALLEY, Hownstin, Pa. Filed June 1, 1905. Serial No. 263,275.



Claim.—1. In combination with a return-ball, a tongue of flexible material secured thereto, said tongue being buckled intermediate of its ends and a string secured to said tongue, the tongue when flexed producing a noise, substantially as shown and described.

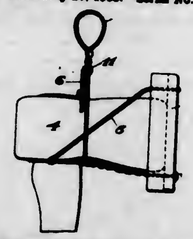
2. In combination with a return-ball, a tongue of spring metal secured to said ball and having its central portion kinked, and a string secured to the free end of said tongue, substantially as shown and described.

3. A return-ball comprising a cup, a rigid cap secured to said cup, a tongue of flexible material secured to the inside of said cap, said tongue being buckled intermediate of its ends and a string passed through said hold and secured to the tongue of flexible material, said tongue when flexed producing a noise, substantially as shown and described.

4. A return-ball comprising a cup, a rigid cap secured to said cup, a tongue of spring metal secured to said cap and having its central portion kinked, and a string secured to the free end of said tongue, substantially as shown and described.

5. A return-ball comprising a cup, a rigid cap secured to said cup and having a hole therein, a tongue of spring metal secured to said cap inside of the ball and having its central portion kinked, and an elastic string secured to the free end of the tongue and extended through the hole in the cap, substantially as shown and described.

810,614. AX HOLSTER AND GUARD. JOHN G. BUSCH, Potter Valley, Cal. Filed July 27, 1905. Serial No. 271,456.



Claim.—1. An ax-guard consisting of a channeled piece adapted to fit the edge of the ax, a wire frame connecting with said guard having a socket through which the handle of the ax may pass, and means connected therewith for the suspension of the ax and holder.

2. An ax-holder having a rigid channeled guard into which the edge of the ax is adapted to fit, a wire frame riveted to the guard and having its members separated to form a socket for the ax-handle, braces extending from the socket portion upon each side and connected with the guard, and a holster or suspending device secured to the wire framework.

3. An ax-holder having a rigid channeled guard into which the edge of the ax is adapted to fit, a wire frame riveted to the lower part of the guard and having its members separated to receive the ax-handle, a second wire frame fixed to the upper end of the guard and connected with the first portion, a hanger or carrier from which the ax and holder are suspended, and a locking-pin and swiveled carrier therefor adapted to secure the ax to the guard and holder.

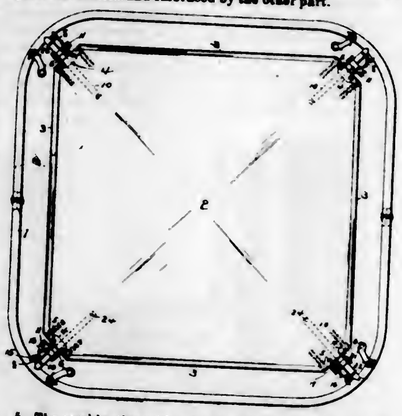
810,615. FIRE-ESCAPE. JAMES F. BUTLER, Scranton, Pa. Filed May 19, 1904. Serial No. 208,682.

Claim.—1. A friction device for a fire-escape, comprising a wedge and spring members embracing said wedge and adapted to move thereon.

2. The combination with a frame, and a blanket or net, of friction devices connecting the blanket or net to the frame and operating to prevent rebound of the blanket or net.

3. A fire-escape comprising a blanket or net, a support, a wedge, and spring members embracing said wedge and adapted to move thereon, said wedge and spring members disposed between the blanket and support.

4. The combination with a frame and a blanket or net, of a series of two-part friction devices for connecting the blanket or net to the frame, one part of each friction device being wedge-shaped in longitudinal section and embraced by the other part.



5. The combination with a frame and a blanket or net, of a series of connecting devices, each comprising a wedge-shaped bar and a yoke, the latter embracing said wedge and adapted to move thereon.

6. The combination with a frame and a blanket or net, of a series of connecting devices, each comprising a wedge-shaped bar having means at one end for its attachment to the frame and a stop at its opposite end, and a yoke embracing the wedge and adapted to move thereon.

7. The combination with a frame and a blanket or net, of a series of devices connecting said parts, each connecting device comprising a wedge-shaped bar and a spring-yoke to engage the sides of the bar and a U-shape reinforcing-spring engaging the yoke near its free ends.

8. A connecting device for fire-escapes, comprising a spring clamp or yoke, a rigid frame located between the members of said yoke, a reinforcing-spring engaging the members of said yoke, and a wedge-shaped bar adapted to be engaged by the yoke.

9. A connecting device for fire-escapes, comprising a spring clamp or yoke having two L-shaped members, a rigid frame located between the members of said yoke, a reinforcing-spring engaging the members of said spring-yoke, means for securing said parts together, a wedge-shaped bar adapted to be engaged by the members of the spring-yoke, and means for connecting the wedge and yoke to the blanket and frame.

10. A connecting device for fire-escapes comprising a spring clamp or yoke having its two members made with laterally-projecting portions, a rigid frame located between the members of said spring-yoke and provided with a handle or grip, and a wedge-shaped bar adapted to rest between the laterally-projecting portions of the members of said yoke.

11. The combination with a frame, a blanket or net, and a series of plates secured to said blanket or net, each plate being provided with loops, of a spring-yoke having means for engaging the loops on the plate, a wedge-shaped bar engaging said spring-yielding yoke and means for connecting the the wedge-shaped bar to the frame.

810,616. FOLDING TABLE. HERMANN BUTTER, Düsseldorf, Germany. Filed Apr. 9, 1904. Serial No. 202,204.

Claim.—A folding table provided with a plate, legs hinged thereto, transverse connecting-ties, ribs secured to the plate, notched rails slidable upon the ribs and adapted to engage the legs, slotted

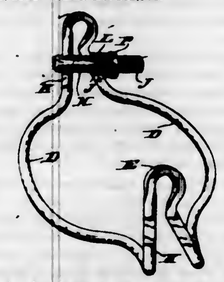
lugs on the rails, pins on the ribs that engage said lugs, and means for locking the rails to the legs, substantially as specified.

810,617. NASAL SHIELD. THOMAS GARDNER, Salina, Kans. Filed Jan. 3, 1905. Serial No. 239,246.

Claim.—1. A nasal shield composed of two thimble-shaped members having flanges extending substantially at right angles to the walls of the thimbles, and absorbent pads surrounding the thimbles, of the same or approximately the same depth as the latter, the flanges being provided with fastening devices which engage the absorbent pads and hold them in place on the thimbles, the latter being provided with mesh diaphragms for the purpose set forth.

2. A nasal shield composed of two thimble-shaped members having flanges at their outer extremities extending substantially at right angles to the walls of the thimbles and provided with laterally-projecting, inwardly-extending fastening devices, absorbent pads surrounding the thimbles, of the same depth as the latter and held in place by the fastening devices, the inner extremities of the thimbles being provided with mesh diaphragms for the purpose set forth.

810,618. INSULATOR-CLAMP. WALTER G. CLARK, Seattle, Wash. Filed Apr. 13, 1904. Serial No. 202,971.



Claim.—1. An insulator-clamp, comprising a body portion adapted to be secured to the insulator, said body being provided with open wire-holding loops formed in one continuous piece with the body and extending at an angle to the plane of said body, the loops being adapted to hold the wire down upon the top of the insulator when the clamp is in position thereon, for substantially the purposes set forth.

2. An insulator-clamp, comprising a body portion adapted to be secured to the insulator, said body being provided with open wire-holding loops formed in one continuous piece with the body and extending at an angle to the plane of said body, the loops being adapted to hold the wire down upon the top of the insulator when the clamp is in position thereon, and means for tightening the parts of the body portion of the clamp upon the insulator, for substantially the purposes set forth.

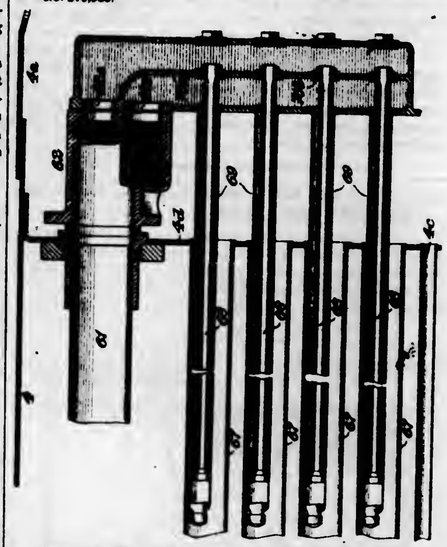
3. An insulator-clamp, comprising a body portion adapted to be secured to the insulator, open wire-holding loops extending at an angle to the plane of the body portion of the clamp and adapted to hold the wire down upon the top of the insulator when the clamp is in position thereon, said loops having neck portions formed of the sides of the loops and means for drawing the necks of said wire-holding loops together to tighten the body portion of the clamp upon the insulator, for substantially the purposes set forth.

4. An insulator-clamp, comprising a body portion adapted to be secured to the insulator, open wire-holding loops extending at an angle to the plane of the body portion of the clamp and adapted to hold the wire down upon the top of the insulator when the clamp is in position thereon, and slotted screws arranged over the wire-holding loops, followers movable in the screw-slots, and nuts rotatable on the followers and forming one piece therewith, for substantially the purposes set forth.

5. The combination with an insulator, of a clamp comprising a body portion encircling the insulator, and wire-holding loops projecting therefrom and extending above the top of the insulator and adapted to hold the wire down thereon whereby the strain on the wire is prevented from being thrown upon the clamp, for substantially the purposes set forth.

6. The combination with an insulator, of a clamp comprising a body portion encircling the insulator, wire-holding loops projecting therefrom and extending above the top of the insulator and adapted to hold the wire down thereon, whereby the strain on the wire is prevented from being thrown upon the clamp, and means for tightening the body portion of the clamp upon the insulator, for substantially the purposes set forth.

810,619. STEAM-BOILER SUPERHEATER. FRANCIS J. COLE, New York, N. Y., assignor to American Locomotive Company, New York, N. Y., a Corporation of New York. Filed Sept. 5, 1905. Serial No. 276,955.



Claim.—1. The combination, with a tubular steam-boiler, of superheating-tubes, outer superheater-pipes projecting thereinto and having their rear ends closed, inner circulating-pipes open at both ends and located within the outer superheater-pipes, an insertible and removable header, partitioned vertically into two chambers, communicating, respectively, with the outer superheater-pipes and the inner circulating-pipes of a vertical row, a steam-supply connection opening into the header-chamber of the outer pipes, and a steam-delivery connection leading out of the header-chamber of the inner pipes.

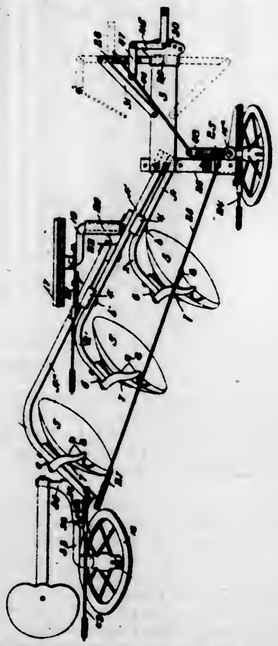
2. The combination with a tubular steam-boiler, of superheating-tubes, outer superheater-pipes projecting thereinto and having their rear ends closed, inner circulating-pipes open at both ends and located within the outer superheater-pipes, a plurality of insertible and removable headers, each partitioned vertically into two chambers, communicating, respectively, with the outer superheater-pipes and the inner circulating-pipes of a vertical row, a T-head partitioned into a supply-compartment which is open to the main-supply steam-pipe and a delivery-compartment which is open to a delivery steam-pipe, ports in the supply-compartment communicating with the header-chambers of the outer pipes, and ports in the delivery-compartment communicating with the header-chambers of the inner pipes.

3. The combination, with a tubular steam-boiler, of superheating-tubes, outer superheater-pipes projecting thereinto and having their rear ends closed, inner circulating-pipes open at both ends and located within the outer superheater-pipes, an insertible and removable header, partitioned vertically into two chambers, communicating, respectively, with the outer superheater-pipes and the inner circulating-pipes of a vertical row, a non-conducting medium interposed between the inner and the outer pipes, a steam-supply connection opening into the header-chamber of the outer pipes, and a steam-delivery connection leading out of the header-chamber of the inner pipes.

4. The combination, with a tubular steam-boiler, of superheating-tubes, outer superheater-pipes projecting thereinto and having their rear ends closed, inner circulating-pipes open at both ends and located within the outer superheater-pipes, an insertible and removable header partitioned vertically into two chambers, communicating, respectively, with the outer superheater-pipes and the inner circulating-pipes of a vertical row, casings of non-conducting material, as asbestos paper, surrounding the circulating-pipes, a steam-supply connection opening into the header-chamber of the outer pipes, and a steam-delivery connection leading out of the header-chamber of the inner pipes.

5. The combination, with a tubular steam-boiler, of superheating-tubes, outer superheater-pipes projecting thereinto and having their rear ends closed, inner circulating-pipes open at both ends and located within the outer superheater-pipes, an insertible and removable header partitioned vertically into two chambers, communicating, respectively, with the outer superheater-pipes and the inner circulating-pipes of a vertical row, casings of non-conducting material, as asbestos paper, surrounding the circulating-pipes, jacket-pipes inclosing and forming dead-air spaces around said casings, a steam-supply connection opening into the header-chamber of the outer pipes, and a steam-delivery connection leading out of the header-chamber of the inner pipes.

810,620. DISK PLOW. WILLIAM S. COOK, San Jose, Cal. Filed Feb. 26, 1904. Serial No. 196,209.



Claim.—1. The combination in a disk plow, of beam-sections having a substantially straight front portion, said front portions arranged one parallel with the other and overlapping each other, a draft-bar in the line of travel of the machine, attachments by which the straight portion of the front section is supported therefrom at an angle divergent from the line of travel, said sections having curved rear ends extending at an opposite angle from the front portion, means for supporting revoluble disks from said curved rear ends of the beams and locking-blocks interposed between and interlocking with the overlapping beam-sections and bolts whereby the parallel straight portions of a plurality of beams are rigidly united.

2. The combination in a disk plow of a sectional beam composed of a plurality of straight L-shaped overlapping sections, having parallel straight front portions arranged at an angle with the line of draft, and having bent rear portions, correspondingly-shaped locking-blocks fitting the contiguous concavities of the beam-sections and bolts whereby said blocks and a straight front portion of a plurality of sections are rigidly locked together, a draft-bar to which said beams are united so that the front portions extend diagonally away from the line of travel, and their rear ends diagonally in the opposite direction, standards fixed to said rear ends and journals by which the disks forming the plows are revolubly connected with the standards.

3. A plow comprising a diagonally-disposed sectional plow-beam, with means for rigidly uniting said sections, each section having the rear end bent inwardly toward and diagonally across the line of draft, revoluble plowing-disks supported from the inturned ends of the sections, a forward vertically-adjustable furrow-wheel, an intermediate adjustable land-wheel located upon the opposite side of the plow and a rear angularly-disposed supporting-wheel, an inclined axle upon which said wheel is turnable, said axle being bent and having a vertical and a horizontal portion, a sleeve within which said vertical portion is turnable, and a block having a downwardly-projecting arm adapted to engage the arm of the axle to maintain the wheel in its line of travel, said block having its lower end inclined diagonally to the horizontal portion of the axle.

4. A gang-plow consisting of a beam supported diagonally to the line of travel of the machine and having a revoluble disk plow connected therewith, land and furrow wheels by which the front of the plow is supported, a rear wheel having a bent and inclined axle, said axle having a vertical swivel-post, a box in which the post is freely turnable, a locking block and arm adapted to engage the bent axle to maintain the wheel substantially in line of travel, said block and arm being movable to disengage from the axle to allow the wheel to swivel when the machine is turned to the right, and said block having the lower end inclined diagonally with the horizontal portion of the axle.

5. A gang-plow comprising a beam and a plurality of plows carried thereby, land and furrow wheels, a vertical turning post upon which the front furrow-wheel is carried, a crank-arm connecting therewith, a lever centrally fulcrumed to the end of said crank, a rod connecting one end of said lever with a hand-lever and a second rod connecting the opposite end of the lever with a bell-crank lever to which the draft-team is attached.

6. The combination with a gang-plow, the draft-bar, bearing-wheels and turnable furrow-wheel, of a bell-crank lever having its angle pivoted at the front of the draft-bar, a connection with one arm for the attachment of the team, a rod connecting the other arm with a centrally-fulcrumed lever, a crank-arm fixed to the turning post of the furrow-wheel, upon which arm the said lever is fulcrumed, and a rod connecting the opposite end of the lever with the driver's lever whereby the furrow-wheel may be turned either by turning the team or by the hand-lever.

7. In a gang-plow, a bent beam, having a straight front portion arranged at an angle with the draft and having a rear portion extending diagonally with the front portion, a draft-bar with which said beam is connected so that the beam stands diagonally across the line of travel, a revoluble disk plow journaled to the rear diagonal portion of the beam, furrow, land and trailing wheels upon which the beam is adjustably carried, and means connecting with the furrow-wheel and the draft attachments by which the direction of travel may be varied either manually or by the turning of the team.

8. In a gang-plow with beams and disks journaled thereto as shown, a vertical swivel-post by which the furrow-wheel is carried, an arm fixed to the post, a second arm centrally pivoted to the end of the first-named arm, a turnable bell-crank lever to one arm of which the team is connected, connection between the other arm of the bell-crank lever and one end of the second pivoted arm aforesaid, and a connection between the other arm of said pivoted arm and a manually-operated lever.

9. In a disk plow, a plow-beam diagonally supported with relation to the line of travel, vertically-adjustable furrow and land-side wheels, a freely-swiveling trail-wheel, a vertical turning post having a horizontal axle portion for the trail-wheel, and a stop-block movable to lock or to release the trail-wheel, and having its lower end inclined diagonally to the horizontal portion of the axle.

810,621. AUTOMATIC OILER. JOHN COOPER, Bellevue, Pa., assignor to The Ingersoll-Sergeant Drill Company, New York, N. Y., a Corporation of West Virginia. Filed Aug. 26, 1905. Serial No. 275,889.

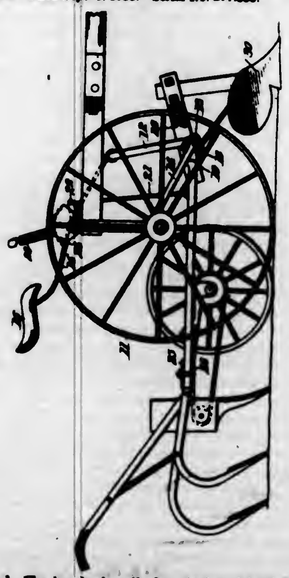
Claim.—1. An automatic oiler for an air-feed pipe comprising a reservoir having its chamber provided with contracted bores for the attachment of adjacent ends of air-feed-pipe sections, a tube leading through the chamber having its ends located in said contracted bores and ducts for opening communication from the chamber to the air-feed-pipe sections at the opposite ends of the said tube.

2. An automatic oiler for an air-feed pipe comprising a reservoir having its chamber provided with contracted bores for the attachment of the adjacent ends of air-feed-pipe sections, a tube leading through the chamber having its ends located in said contracted bores and ducts in the exterior walls of the ends of the tube for opening communication from the chamber to the air-feed-pipe sections for permitting the escape of oil at one end of the tube and the admission of air at the other end of the tube.

3. An automatic oiler for an air-feed pipe comprising a reservoir having its chamber provided with contracted bores for the attachment of the adjacent ends of the air-feed-pipe sections, a tube leading through the chamber having its ends fitted to the said bores, there being ducts for opening communication between the chamber and the air-feed-pipe sections at the opposite ends of the tube for permitting the escape of oil in small quantities at one end of the tube and the admission of air in small quantities at the other end of the tube and an air-tight filling-cap for the said chamber.

4. An automatic oiler for an air-feed pipe comprising a reservoir having its chamber provided with contracted bores for the attachment of the adjacent ends of the air-feed-pipe sections, a tube leading through the chamber having its ends fitted to the bores and ducts at the opposite ends of the tube for permitting the escape of oil from the chamber at the one or the other end of the tube according to the direction of flow of air through the air-feed pipe and the admission of air from the pipe to the chamber at the opposite end of the tube from the end where the oil is permitted to escape.

810,622. AGRICULTURAL IMPLEMENT. JESSE U. CORNELISON, Buda, Tex. Filed Sept. 8, 1905. Serial No. 277,586.



Claim.—1. The herein-described agricultural implement comprising a frame formed of U-shaped frame-bars, carrying-wheels mounted upon one of said frame-bars, side bars connected to the other frame-bar, a cross-bar secured to the free ends of said side bars, and converging bars mounted between the forward ends of said side bars, said converging bars being reversible and coöperating with said cross-bar to interchangeably secure various agricultural implements between said side bars.

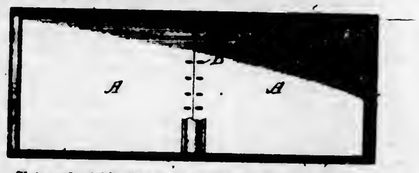
2. The herein-described agricultural implement comprising a frame provided with side bars supported at their forward ends, a cross-bar secured to the free ends of said side bars, and converging bars mounted between the forward ends of said side bars, said converging bars being reversible, and coöperating with said cross-bar to interchangeably secure various agricultural implements between said side bars.

3. The herein-described agricultural implement comprising a frame provided with side bars supported at their forward ends, a cross-bar secured to the free ends of said side bars, converging bars pivotally mounted between the forward ends of said side bars, whereby the same may be reversed, and means for holding said converging bars from pivotal movement, said converging bars coöperating with said cross-bar to interchangeably secure various agricultural implements between said side bars.

4. The herein-described agricultural implement comprising a frame provided with side bars supported at their forward ends by an approximately universal joint, a cross-bar secured to the free ends of said side bars, and converging bars mounted between the forward ends of said side bars, said converging bars being reversible, and coöperating with said cross-bar to interchangeably secure various agricultural implements between said side bars.

5. The herein-described agricultural implement comprising a frame provided with side bars supported at their forward ends by an approximately universal joint, means for adjusting said side bars vertically, a cross-bar uniting the free ends of said side bars, and converging bars mounted between the forward ends of said side bars, said converging bars being reversible, and coöperating with said cross-bar to interchangeably secure various agricultural implements between said bars.

810,623. BLACKBOARD. THOMAS H. COSTELLO, Chicago, Ill. Filed Aug. 18, 1905. Serial No. 274,067.



Claim.—1. A blackboard comprising a flexible metallic foundation, and a flexible pigmented abrasive layer on the foundation.

2. In a blackboard a flexible metallic foundation having elongated openings for attaching the same, and a flexible pigmented abrasive layer on the foundation.

3. In a blackboard a foundation of flexible steel, and a flexible pigmented abrasive layer on the foundation.

4. In a blackboard a foundation of leveled flexible steel, and a flexible pigmented abrasive layer on the foundation.

810,624. PRESSURE-CONTROLLING DEVICE FOR THE AIR-SPRINGS OF PRINTING-PRESSES. CHARLES F. COTTRELL, Westerly, R. I., assignor to C. B. Cottrell & Sons Company, New York, N. Y., a Corporation of New Jersey. Filed Apr. 4, 1905. Serial No. 253,787.

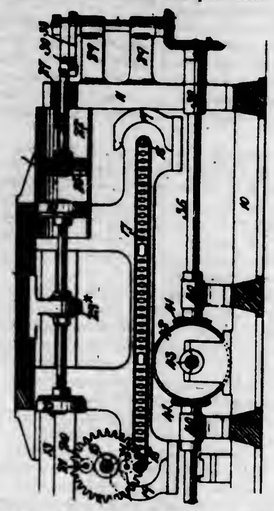
Claim.—1. In a reciprocating-bed printing-press, the combination with an air-spring cylinder and piston, of a cylinder-head movable within said cylinder lengthwise thereof, the movement of the cylinder-head being timed with respect to the movement of the press-bed.

2. In a reciprocating-bed printing-press, the combination with an air-spring cylinder and piston, of a cylinder-head movable within said cylinder lengthwise thereof while the piston is in the cylinder, the movement of the cylinder-head being timed with respect to the movement of the press-bed.

3. In a reciprocating-bed printing-press, the combination with an air-spring cylinder and a piston fitted thereto the one stationary and the other carried by the press-bed, of a cylinder-head fitted to said cylinder and movable lengthwise thereof while the piston is in the cylinder, the movement of the cylinder-head being timed with respect to the movement of the press-bed.

4. In a reciprocating-bed printing-press, the combination with a stationary air-spring cylinder and a piston fitted thereto and carried by the bed, of a cylinder-head fitted to said cylinder and movable

therein lengthwise thereof, the movement of the cylinder-head being timed with respect to the movement of the press-bed.



5. In a reciprocating-bed printing-press, the combination with an air-spring cylinder and piston, of a cylinder-head fitted to said cylinder, and automatically-operating mechanism for moving said cylinder-head within the cylinder relatively to the piston.

6. In a reciprocating-bed printing-press, the combination with an air-spring cylinder and piston, of a cylinder-head fitted to the said cylinder and movable therein lengthwise thereof and cam-actuated mechanism for controlling the movement of said cylinder-head away from the piston while the latter is moving within the cylinder.

7. In a reciprocating-bed printing-press, the combination with an air-spring cylinder and a piston fitted thereto the one stationary and the other carried by the press-bed, of a cylinder-head fitted to said cylinder and movable therein lengthwise thereof, and automatic means for controlling and changing the position of said head while the piston is in the cylinder.

8. In a reciprocating-bed printing-press, the combination with a stationary air-spring cylinder and an air-spring piston carried by the bed, of a cylinder-head fitted to said cylinder and movable therein lengthwise thereof, and means timed with respect to the movement of the press-bed for controlling and changing the position of said head relatively to said piston.

9. The combination with a printing-press bed and mechanism for giving said bed a reciprocating movement retarded at a certain stage of its progress, of an air-spring cylinder and piston, a cylinder-head movable in said cylinder lengthwise thereof and mechanism timed to the travel of the bed for controlling the movement of said cylinder-head within the cylinder during the retarded portion of said movement of the bed.

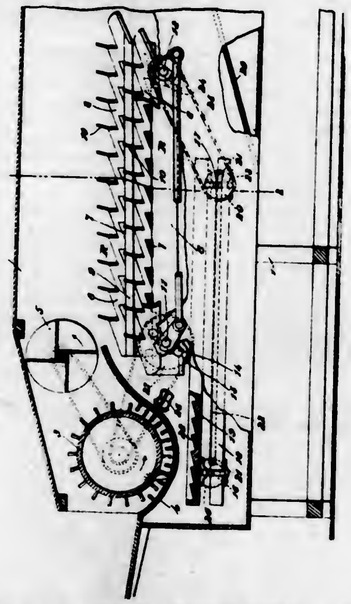
10. The combination with a printing-press bed and mechanism for giving said bed a reciprocating movement, of a stationary air-spring cylinder, a piston carried by the bed, a cylinder-head fitted to said cylinder and movable therein lengthwise thereof and mechanism timed to the travel of the bed for controlling the movement of the said cylinder-head away from the piston while the latter is moving within the cylinder.

11. The combination with a printing-press bed and mechanism for giving the bed a reciprocating movement, of a stationary air-spring cylinder, a piston carried by the press-bed, a cylinder-head fitted to the said cylinder and movable therein lengthwise thereof and mechanism for controlling the movement of the cylinder-head whereby the cylinder-head is held stationary during the first part of the advance movement of the piston within the cylinder and then permitted to move in the same direction as the piston.

12. The combination with a printing-press bed and mechanism for giving said bed a reciprocating movement, of a stationary air-spring cylinder, a piston carried by the press-bed, a cylinder-head fitted to the said cylinder and movable therein lengthwise thereof and mechanism for controlling the movement of the said cylinder-head whereby the cylinder-head is held stationary during the first part of the advance movement of the piston within the cylinder, then permitted to move in the same direction as the piston and then held stationary while the piston starts on its reverse movement.

13. The combination with a printing-press bed and mechanism for giving said bed a reciprocating movement, of a stationary air-spring cylinder, a piston carried by the press-bed, a cylinder-head fitted to the said cylinder and movable therein lengthwise thereof and mechanism for controlling the movement of said cylinder-head whereby the cylinder-head is held stationary during the first part of the advance movement of the piston within the cylinder, then permitted to move in the same direction as the piston, then held stationary while the piston starts on its reverse movement and finally moved to its normal position within the cylinder.

810,625. SEPARATOR. JAMES D. CRANE, Aledo, Tex. Filed July 7, 1905. Serial No. 268,692.



Claim.—1. In a separator, a straw-rack including a plurality of independent rake-sections; each of said rake-sections including a longitudinal supporting bar or beam, wedge-shaped slats supported transversely upon said beam, and zigzag bars supported upon said cross-slats.

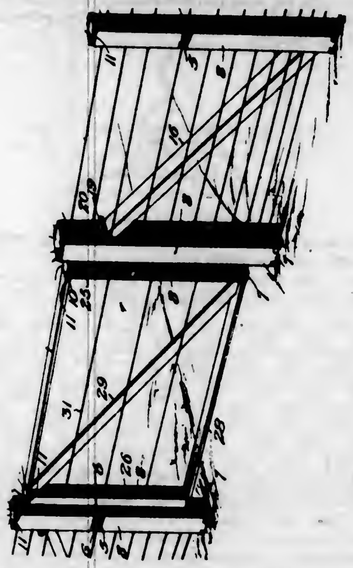
2. In a device of the class described, a rake-section including a longitudinal supporting-bar, cross-slats upon said bar having inclined upper sides, zigzag bars supported upon said cross-slats, and reinforcing-bars connected with the under sides of the cross-slats and with the intervening portions of the zigzag bars.

3. In a device of the class described, a rake-section including a longitudinal supporting-bar, wedge-shaped cross-slats upon said bar, zigzag bars upon said cross-slats, and upwardly and rearwardly inclined prongs connected with said bars.

4. In a separator, a straw-rack including a plurality of independent sections, a pair of crank-shafts, having cranks supporting said independent sections for gyratory movement in vertical planes, a plurality of grain-pans disposed adjacent to each other and extending beneath the straw-rack, a pair of shafts having cranks supporting said grain-pans for gyratory movement in vertical planes and in opposite directions, driving means applied to one of the crank-shafts supporting the straw-rack sections, and means for transmitting motion between the shafts supporting the straw-rack sections and the shafts supporting the grain-pans.

810,626. FENCE STRUCTURE. MARTHA R. DAVIS, Worthington, Minn. Filed Apr. 26, 1905. Serial No. 257,291.

Claim.—1. In a fence structure, a post provided with wire-receiving grooves upon the face thereof, a retaining-plate hinged or pivoted at its lower end to the post to swing toward and from said face and adapted to when swung against the face to clamp the wires in the grooves, and means for engaging the upper end of the plate and retaining it in clamping position.



2. In a fence structure, a post provided in the face thereof with transverse wire-receiving grooves and slots intersecting said grooves, a retaining-plate hinged at one end to the post and provided with spaced retaining elements to engage the wires and hold them seated in the grooves, said retaining elements being adapted to enter said slots, and means upon the post to engage the free end of the plate and hold it in operative position.

3. In a fence structure, a post provided upon the face thereof with grooves, a retaining-plate hinged at its lower end to the post and adapted to fold against the same to hold the wires seated in said grooves, said plate being provided at its upper end with a projection, and a keeper hinged to the top of the post and adapted to engage said projection to hold the plate in retaining position.

4. In a fence structure, a post provided with slots therein, a retaining element adapted to bear against the post and provided with retaining-pins adapted to engage the fence-wires and to enter said slots, and means movably mounting said element upon the post whereby the same may be moved out of engagement with the post to release the wires.

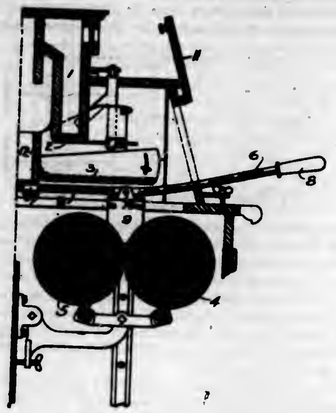
810,627. TRUING DEVICE FOR FLOUR-MILL ROLLS. CHARLES DAWSON, Tacoma, Wash. Filed Apr. 26, 1905. Serial No. 257,294.

Claim.—1. In a truing device for cylindrical rolls, the combination of an abrasive body formed to engage a roll, a handle-bar, a pivoted connection between said handle-bar and said abrasive body.

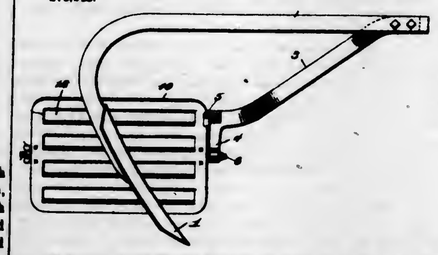
2. In a truing device for cylindrical rolls, the combination of an abrasive body adapted to engage a roll, a bar having a handle at one end and engaging the machine at the other end to form a fulcrum, and a pivoted connection between said bar and said abrasive body.

3. In a truing device for cylindrical rolls, the combination of an abrasive body adapted to engage a roll, a bar having a handle at one end, a roller mounted on the other end of said bar to form a movable fulcrum by engaging the machine, and pivoted connections between said bar and said abrasive body.

4. In a truing device for cylindrical rolls, the combination of an abrasive body adapted to engage a pair of rolls at the same time, a bar having a handle at one end, a roller mounted on the other end of said bar and adapted to engage the machine to form a fulcrum whereby pressure may be communicated to said abrasive body, and a pivoted connection between said bar and said abrasive body whereby the pressure thereon is equally applied to both the rolls.



810,628. SHIELD ATTACHMENT FOR CULTIVATORS. HARRY H. DENNIS, Lunda, Ohio. Filed Aug. 28, 1905. Serial No. 276,142.



Claim.—1. A shield attachment for cultivators comprising a rotatable slotted plate, a support therefor, means for holding the plate against rotation, and an inclined flange extending from one edge of the slot.

2. A shield attachment for cultivators comprising a supporting member, a rotatable longitudinally-slotted plate connected to said member, a flange extending longitudinally upon one side of the plate and from one edge of the slot at an acute angle to the plate, and means for locking the plate against rotation.

3. A shield attachment for cultivators comprising a supporting-arm, a shield-plate rotatably connected to the arm, means for locking the plate to the arm to prevent rotation, said plate having a plurality of longitudinally-extending slots, and longitudinally-extending flanges projecting from the edges of the slots at acute angles to the plate.

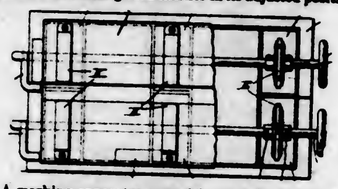
4. A shield attachment for cultivators comprising a supporting-arm, a rod extending therefrom, a longitudinally-slotted plate rotatably mounted upon the rod, plate-engaging means on the arm, means for locking the plate in engagement with said means, and flanges extending from the plate and adjacent the slots at acute angles to the plate.

5. A shield attachment for cultivators comprising an arm having a rack thereon, a rod extending from the arm, a plate rotatably mounted upon the rod and adapted to engage the rack, said plate having a plurality of longitudinally-extending slots therein, means for locking the plate in engagement with the rack, and flanges upon the plate and adjacent the slots, said flanges being disposed at acute angles to the plate.

810,629. MARKING APPARATUS. WILLIAM J. DIX, Milford, Mass. Filed July 10, 1905. Serial No. 269,602.

Claim.—1. A marking apparatus comprising a series of tanks for containing marking material of different colors, a rotary marker provided with an absorbent periphery mounted in each of said tanks

to present a portion of its periphery above the surface of said material, means for rotarily adjusting each of said markers to bring a fresh portion of its periphery above the surface of the marking material, means for retaining each marker in its adjusted position.



2. A marking apparatus comprising a series of tanks for containing marking material of different colors, a rotary marker provided with an absorbent periphery mounted in each of said tanks to present a portion of its periphery above the surface of said material, means for rotarily adjusting each of said markers to bring a fresh portion of its periphery above the surface of the marking material, a cover for said apparatus presenting openings for the projection therethrough of the periphery of each of said markers and removable from the tanks and markers.

3. A marking apparatus comprising a series of tanks for containing marking material of different colors, a rotary marker provided with an absorbent periphery mounted in each of said tanks to present a portion of its periphery above the surface of said material, means for rotarily adjusting each of said markers to bring a fresh portion of its periphery above the surface of the marking material, a cover for said apparatus presenting openings for the projection therethrough of the periphery of each of said markers, auxiliary covers for each of said openings.

4. A marking apparatus comprising a series of tanks for containing marking material of different colors, a rotary marker provided with an absorbent periphery mounted in each of said tanks to present a portion of its periphery above the surface of said material, means for rotarily adjusting each of said markers to bring a fresh portion of its periphery above the surface of the marking material, a cover for said apparatus presenting openings for the projection therethrough of the periphery of each of said markers, auxiliary covers for each of said openings pivoted to said main cover.

5. A marking apparatus comprising a series of tanks for containing marking material of different colors, a rotary marker provided with a plurality of absorbent faces mounted in each of said tanks to present one of its faces above the surface of said material, means for rotarily adjusting said markers.

6. A marking apparatus comprising a series of tanks for containing marking material of different colors, a rotary marker provided with a plurality of absorbent faces mounted in each of said tanks to present one of its faces above the surface of said material, means for rotarily adjusting said markers, means for locking each of said markers in adjusted position.

7. A marking apparatus comprising a series of tanks for containing marking material of different colors, a rotary marker provided with a plurality of absorbent faces mounted in each of said tanks, to present one of its faces above the surface of said material, a cover for said apparatus presenting openings for the projection therethrough of the exposed face of said markers.

8. A marking apparatus comprising a series of tanks for containing marking material of different colors, a rotary marker provided with a plurality of absorbent faces mounted in each of said tanks, to present one of its faces above the surface of said material, a cover for said apparatus presenting openings for the projection therethrough of the exposed face of said markers, means for rotarily adjusting said markers and locking the same in adjusted position.

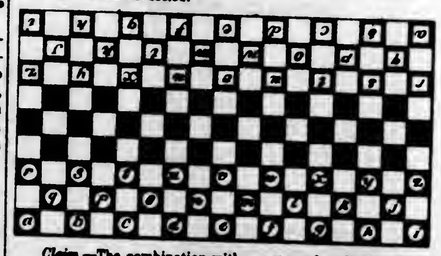
9. In a marking apparatus, a rotary marker, comprising a wheel-frame, presenting a polygonal periphery, a shaft therefor, stripe of absorbent material, means for clamping said stripe on said frame to project beyond the periphery thereof, and present a series of absorbent faces.

10. In a marking apparatus, a series of tanks, for containing marking material of different colors, a second series of tanks above and behind said first series, a frame for supporting said tanks, a series of rotary markers, one mounted in each tank, and each provided with an absorbent periphery, means for rotarily adjusting each of said markers, means for retaining each marker in its adjusted position.

810,680. ERASER-MAKING DEVICE. GEORGE C. DUSSERT, New York, N. Y. Filed Sept. 14, 1904. Serial No. 224,269.

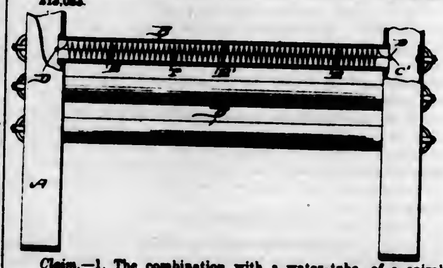
Claim.—A device of the class described, consisting of an oblong box substantially triangular in cross-section and completely closed, said device comprising a frame composed of transverse bottom members to which the bottom proper is secured, transverse brace-frames connected with said bottom members, and side and end boards rigidly connected and also rigidly connected with said frames, the top portion of the box being provided with an extension parallel with one side thereof and at an angle to the other side, substantially as shown and described.

810,681. GAME. SYLVANUS F. BUSH, Matteson, Ill. Filed Apr. 17, 1905. Serial No. 256,047.



Claim.—The combination with a rectangular checkered gameboard having nine rows of seventeen spaces each, the spaces of each row being of two colors arranged alternately; of two sets of gamepieces each adapted to be placed entirely upon three of the nine rows of spaces and upon spaces of the same color, the pieces of each set being designated by the letters of the alphabet and no two of said pieces of each set being designated by the same letter.

810,682. BOILER ATTACHMENT. JOHN P. FARRITY and JOSEPH H. M. BLACKFORD, Duquesne, Pa. Filed June 17, 1904. Serial No. 213,083.



Claim.—1. The combination with a water-tube, of a spiral spring arranged within the tube, and perforated disks carried by the said spring.

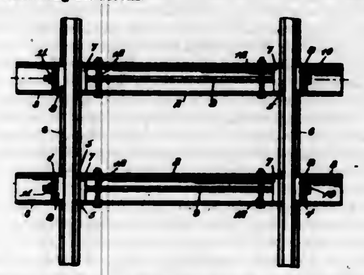
2. The combination with a tube, of a spiral spring arranged in and extending substantially the length of the tube, and perforated disks carried by and arranged within the spirals of the spring.

3. A boiler attachment comprising a spiral spring adapted to be arranged in the water-tube of a boiler, a wire arranged centrally and longitudinally within the spring, means for connecting said wire at the ends of the tube, and perforated disks connected to the spring, said wire passing through the centers of the disks.

4. The combination with a water-tube, of the spirally-coiled wire arranged therein, means for securing the ends of the wire at the ends of the tube, and the perforated disk connected to the wire intermediate its ends, for the purpose described.

810,683. RAIL-TIE. SAMUEL B. FERGUSON and CHARLES CALHOUN, Rome, Miss. Filed Sept. 2, 1905. Serial No. 276,903.

Claim.—1. The combination with a channeled metallic tie having rail-engaging tongues integral therewith; of rail-supporting blocks within the tie, means thereon for engaging the rails, and adjustable means connecting the blocks.

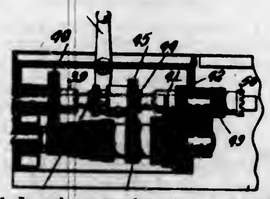


2. The combination with a channeled metallic tie having means thereon for engaging the inner flanges of rails; of rail-supporting blocks within the tie, means thereon for engaging the outer flanges of rails, and an adjusting device connecting the blocks and within the tie.

3. The combination with a channeled metallic tie having integral rail-engaging means; of rail-supporting blocks within the tie, ears thereon adapted to coöperate with the rail-engaging means on the tie for clamping the rails in position, and an adjustable device connecting the blocks.

4. The combination with a channeled metallic tie having integral rail-engaging tongues upon the sides thereof and braces connecting the sides; of rail-supporting blocks adjustably mounted within the tie, rail-engaging ears upon said blocks adapted to coöperate with the tongues to clamp the rails in position, and means connecting the blocks to hold them against displacement.

810,684. CHANGE-SPEED GEARING FOR ENGINE-LATHES. HERBERT L. FLATHER, Nashua, N. H. Filed May 19, 1905. Serial No. 261,180.



Claim.—1. In a change-speed gearing, the combination of a driven shaft, a swinging gear-box having an opening in the periphery thereof, a train of gearing inclosed in the gear-box and turned by the driven shaft, and means for clamping the gear-box in a plurality of different operative positions to act as a sweep with the last gear of the train in engagement with gears of different sizes.

2. In a change-speed gearing, the combination of a driven shaft, a sweep pivoted concentrically with respect to the driven shaft, a train of gears carried by the sweep, means for fastening the sweep in a plurality of different operative positions to set the last gear of the train into engagement with gears of different sizes, said train including a compound gear and a transversely-shiftable compound gear.

3. In a change-speed gearing, the combination of a driven shaft, a gear-box hung to swing upon a center concentric with said shaft, said gear-box comprising a casting and cover-plate therefor, a stud holding the cover-plate in place, said stud being mounted so that it may be adjusted to different positions, a gear fastened on the driven shaft, and a train of gears mounted in the gear-box and turned from said gear on the driven shaft, one of said gears of said train being journaled on the stud which fastens the parts of the gear-box together.

4. In a change-speed gearing, the combination of a driven shaft, a gear on the driven shaft, a sweep pivoted to swing on a center concentric with the driven shaft, a train of gears mounted on the sweep, and means for fastening the sweep in a plurality of different operative positions to set the last gear of the train into engagement with gears of different sizes, said train including a double gear having sections of two different diameters, and a transversely-shiftable gear also having sections of two different diameters.

5. In a change-speed gearing, the combination of a driven shaft, a gear on the driven shaft, a sweep mounted to swing on a center concentric with the driven shaft, a train of gears mounted on the sweep including a compound gear having parts of different diameters, either part of which may be driven from the previous double gear of the train, a wide-faced gear meshing with and driven from the transversely-shiftable gear on the sweep, and means for adjusting the sweep in different positions, whereby use will be permitted of wide-faced gears of different diameters.

6. In a change-speed gearing, the combination of a driven shaft, a swinging gear-box having an opening in the periphery thereof, a train of gearing inclosed in said gear-box and turned by the driven shaft, means for clamping the gear-box in different positions to act as a sweep by swinging the last gear of the train into engagement with gears of different sizes, and a second speed-changing train driven from the gears in the sweep and comprising a set of gears arranged step-like, and a swinging gear which can be set into mesh with the desired one of the gears arranged step-like.

7. In a change-speed gearing, the combination of a driven shaft, a shaft to be driven therefrom, three gears fastened on the driven shaft, two gears loosely mounted on the shaft to be driven, and meshing with the end gears on the driven shaft, and a clutch-piece turning with and longitudinally movable on the shaft to be driven, said clutch-piece having provision for making connection with the end gears when thrown to the limits of its movement, and having a gear for meshing with the middle gear on the driven shaft when the clutch-piece occupies an intermediate position.

8. In a change-speed gearing, the combination of a gear-box, three shafts mounted therein, a transversely-movable shiftable lever pivoted concentrically with the driving-shaft, a series of gears arranged step-like on the intermediate shaft, a gear carried by the lever and adapted to engage any one of the series of gears arranged step-like on the intermediate shaft and a change-speed connection with the shaft to be driven comprising loose clutch-sections driven from two of the gears arranged step-like on the intermediate shaft and a shifting-clutch engaging the loose-running clutch-pieces and having a gear for engaging a third one of the gears arranged step-like.

9. In a change-speed gearing, the combination of two shafts, one a driven shaft and the other a shaft to be driven therefrom, three gears fastened on one shaft, two gears loosely mounted on the other shaft meshing with the end gears on the first shaft, and a clutch-piece turning with and longitudinally movable on the second shaft, said clutch-piece having clutch-teeth for making connection with the end gears when thrown to the limits of its movement, and having a gear meshing with the middle gear on the first shaft when the clutch-piece occupies an intermediate position.

10. In a change-speed gearing, the combination of a driven shaft, a gear on the driven shaft, a gear-box pivoted to swing on a center concentric with the driven shaft, a train of gears inclosed in the gear-box and including a transversely-shiftable compound gear, either section of which may be driven, means for clamping the gear-box in different adjusted positions to act as a sweep, a gear-box secured to the front of the lathe-bed, three shafts mounted in the gear-box, a wide-faced gear on one of said shafts meshing with the final gear of the train carried by the swinging gear-box, a set of gears arranged step-like on the intermediate shaft, a shifting-lever, a transversely-movable intermediate thereon which can be set into engagement with any one of the gears arranged step-like, and change-speed gearing between the intermediate shaft and final gear, comprising end gears loosely mounted on the third shaft and driven from the intermediate shaft, and a movable clutch-piece mounted on the third shaft and having provision for making connection with the loose gears when at the limits of motion in opposite directions, and having a gear meshing with one of the gears on the intermediate shaft when the clutch-piece occupies an intermediate position.

810,685. BUTTON OR CHECK. CHARLES J. FRANK, Baltimore, Md. Filed July 21, 1905. Serial No. 270,727.

Claim.—1. A non-transferable door-check consisting of a button composed of two caps, each provided with a flange, one of said flanges being adapted to fit within the other, a tape or cord connected to the button at one end and at the other end provided with a barb, one of said caps being provided with an opening in its flange into which the barb may be inserted, whereby the two ends of the tape will be securely fastened to the button.

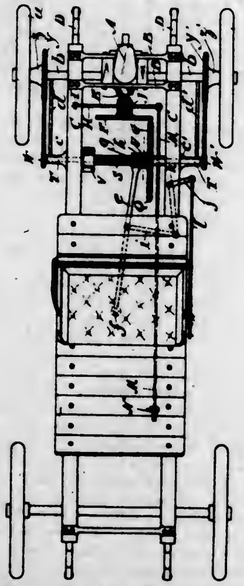
2. A non-transferable door-check consisting of a button composed of two caps secured together, a tape or cord connected to the

button at one end and at the other end provided with a barb, one of

button at one end and at the other end provided with a barb, one of said caps being provided with an opening into which the barb may be inserted, whereby the two ends of the tape may be securely fastened to the button, a flange formed on the side of the opening and extending inward to prevent the withdrawal of the barb.

3. A non-transferable door-check consisting of a button composed of two disks, each provided with a flange, one of said flanges being adapted to fit within the other and one of the disks being provided with an opening, a tape or cord one end of which is secured to the button by being clamped between the flanges of the disks and carrying at its other end a barb adapted to be inserted in the opening in the disks.

810,636. AUTOMOBILE. LEONARD B. GAYLOR, Newton Center, Mass. Filed Mar. 21, 1905. Serial No. 251,238.



Claim.—1. In an automobile the combination of a motor mounted upon a spring-supported frame over a fixed rear axle, a counter-shaft forward of the motor, sprocket-wheels on the counter-shaft, sprocket-chains proceeding from said sprocket-wheels direct to each driven wheel independently and means for transmitting the power of the motor to the counter-shaft at variable speeds.

2. In an automobile the combination of a motor mounted upon a spring-supported frame over a fixed rear axle, a counter-shaft forward of the motor, sprocket-wheels upon the counter-shaft, driven wheels mounted loosely upon a fixed axle, sprocket-wheels on the hub of each driven wheel and sprocket-chains connecting the sprockets upon the counter-shaft with the sprockets upon the hubs of the wheels.

3. In an automobile the combination of a motor mounted upon a spring-supported frame over a fixed rear axle, a sliding friction-disk on the shaft of the motor, a counter-shaft forward of the motor having a driving-wheel thereon presented edgewise to the friction-disk and power-conveying devices such as chains for transmitting motion from the counter-shaft to each of the rear wheels.

4. In an automobile the combination of a motor mounted upon a spring-supported frame over a rear axle, a counter-shaft forward of the motor having fixed bearings, driven wheels mounted upon a rear axle, power-conveying devices, such as chains, connecting the counter-shaft direct with the driven wheels and means for transmitting the power of the motor to the counter-shaft at variable speeds.

5. In an automobile the combination of a motor, a sliding friction-disk on the shaft of the motor, a counter-shaft forward of the motor having a driving-wheel thereon presented edgewise to the friction-disk and means for moving the friction-disk and driving-wheel toward and from each other.

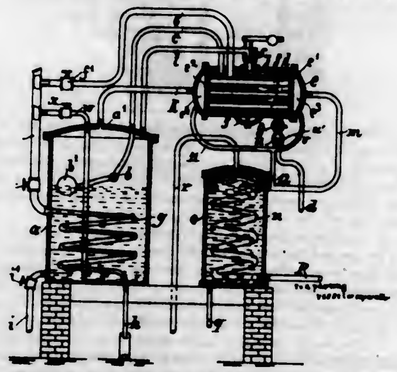
6. In an automobile the combination of a motor, a sliding friction-disk on the shaft of the motor, a counter-shaft forward of the motor having a driving-wheel thereon presented edgewise to the friction-disk, means for moving the friction-disk and driving-wheel toward and from each other and means to shift the driving-wheel across the face of the friction-disk.

7. In an automobile the combination of a motor mounted upon a spring-supported frame, a counter-shaft forward of the motor having fixed bearings, a sliding friction-disk on the shaft of the motor, driven wheels mounted upon a rear axle, power-conveying devices, such as chains, connecting the counter-shaft direct with the driven wheels and means for transmitting the power of the motor to the counter-shaft at variable speeds.

8. In an automobile the combination of a motor, a sliding friction-disk on the shaft of the motor, a counter-shaft forward of the motor having fixed bearings, a driving-wheel on the counter-shaft adapted to transverse movement relative to the friction-disk and means for transmitting the motion of the counter-shaft to the driven wheels.

9. In an automobile the combination of a motor, a sliding friction-disk on the shaft of the motor, a counter-shaft forward of the motor having fixed bearings, a driving-wheel on the counter-shaft adapted to transverse movement relative to the friction-disk and means for transmitting the motion of the counter-shaft to the driven wheels independently.

810,637. APPARATUS FOR CONTINUOUSLY DISTILLING BENZIN AND THE LIKE. AUGUST H. L. GERHARDT, Bottenhausen, near Cassel, Germany. Filed Sept. 15, 1903. Serial No. 173,264.



Claim.—1. In an apparatus of the character described, the combination with a still, of means for heating said still, a heater comprising two sections or compartments, a tube leading from a supply to one of the compartments, a safety-valve on the heater, a tube connecting the outlet of said safety-valve with said still, means for introducing steam in jets into said heater for cleaning same, a blow-off cock on the bottom part of said heater, a supply-tube for conducting the preliminarily-heated liquid from said heater into said still, a float-controlled supply-valve on the end of said supply-tube within said still, a tube connecting the top part of said still with the second compartment of said heater, a condenser, a tube connecting the second chamber of said heater with said condenser, and means for leading off the condensed pure liquid from said condenser.

2. In an apparatus of the character described, the combination

with a still, of a steam-coil within said still, means for conducting steam to said steam-coil, a draining-tube outside said still and connected with said steam-coil, means for admitting steam direct to said still, an internal supply-tube within said still, a float-controlled supply-valve on the free end of said internal supply-tube, a heater, a check-valve attached to the bottom part of said heater, a tube connecting said check-valve with the source of liquid to be distilled, a safety-valve on the top part of said heater and adapted for allowing any vapor developed from the preliminarily-heated liquid to escape, a tube for conducting the vapor escaping from said safety-valve to the top part of said still, means for introducing steam in jets into said heater for cleaning same, a blow-off cock on the bottom part of said heater for discharging the dirt mingled with steam, an external supply-tube for conducting the preliminarily-heated liquid from said heater into said internal supply-tube within said still, a tube connecting the top part of said still with the chamber of said heater adapted to receive the heated medium, a condenser, a tube connecting said chamber of said heater with said condenser, and means for leading off the condensed pure liquid from said condenser.

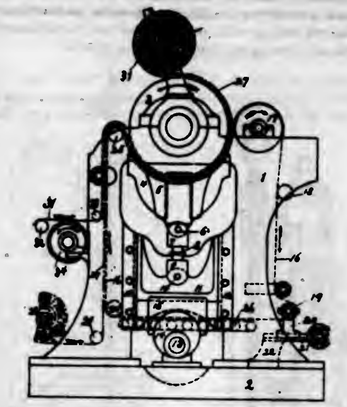
3. In an apparatus of the character described, the combination with a still, of a steam-coil within said still, a steam-supply tube connected with the one end of said steam-coil, a stop-valve inserted in said steam-supply tube, a draining-tube outside said still and connected with the other end of said steam-coil, an internal steam-tube within said still and reaching down to a point above the bottom, a branch tube connecting said internal steam-tube with said steam-supply tube, a stop-valve inserted in said branch tube, a discharging device on the bottom of said still, an internal liquid-supply tube within said still, a float-controlled supply-valve on the free end of said internal liquid-supply tube, a heater comprising collecting-chambers and connecting-tubes for the reception of the heated medium, and a separate space for the medium to be heated, a tube leading from the source of supply to the latter space, a check-valve located in such tube, a safety-valve on the top part of said heater and adapted for allowing any vapor developed from the preliminarily-heated liquid to escape, a tube connecting the outlet of said safety-valve with the top part of said still, a perforated steam-injecting tube within the space of said heater surrounding its heating-tubes, a branch tube connecting said perforated steam-injecting tube with said steam-supply tube and provided with a stop-valve, a blow-off cock on the bottom part of said heater, an external liquid-supply tube leading from the heater to the said internal tube in the still, a tube connecting the top part of said still with the heater, a condenser comprising a coil, a tube connecting the collecting-chamber of said heater with the one end of the coil of said condenser, a series of draining-tubes connecting the distributing-chamber and the collecting-chamber of said heater with said tube leading to the coil of said condenser, means for conducting a cooling fluid to said condenser and for leading off the warmed fluid, and a tube connecting the other end of the coil of said condenser with the place for further treating the condensed pure liquid.

4. In a distilling apparatus, the combination with a still, condenser, and main steam-conducting pipe and of a heater having two chambers therein, a conduit leading from the source of supply to the still in open communication with one of the chambers of the heater, a second conduit leading from the still to the condenser in communication with the other chamber of the heater, a discharge-cock located in the first conduit between the heater and source of supply, and a valve-controlled branch steam-pipe leading from the main steam-pipe to the first-named chamber of said heater, substantially as described.

5. The combination in a distilling apparatus with a still, condenser, and source of supply, of a heater including two compartments, one of said compartments, comprising a collecting-chamber, a distributing-chamber, and tubes providing open communication in between the two, and the second compartment being forged between said collecting and distributing chambers and about said tubes, a conduit leading from the still to the condenser in open communication with the first compartment, a conduit leading from the source of supply to the still in communication with said second compartment, and an auxiliary externally-arranged conduit connecting the collecting-chambers of the first-mentioned compartment of the heater and in communication with the conduit leading from the still to the condenser, substantially as described.

810,638. CLOTH-PRESSING MACHINE. DAVID GRIMES, Worcester, Mass. Filed Aug. 12, 1903. Serial No. 169,288.

Claim.—1. In a rotary cloth-press, in combination, a cylinder, a presser, two aprons running between the same and means whereby one of said aprons is wound up with the cloth.



2. In a rotary cloth-press, in combination, a cylinder, a presser, two aprons running between the same; one of said aprons being endless and the other non-endless and means whereby the non-endless apron is wound up.

3. In a rotary cloth-press, in combination, a cylinder, a presser, means whereby the cloth is conducted between the cylinder and presser, a non-endless apron and means whereby the same is wound up with the cloth.

4. In a rotary cloth-press, in combination, a cylinder, a presser, a dry apron running in contact with the presser and a moist apron running in contact with the cloth between the dry apron and the cloth.

5. In a rotary cloth-press, in combination, a cylinder, a presser, a dry apron running in contact with the presser and a moist apron running with the cloth between the dry apron and the cylinder and means whereby the cloth and said moist apron are wound up together.

6. In a rotary cloth-press, in combination, a cylinder, a presser, a dry apron running between the cloth and presser, a moist apron and means whereby the moist apron is wound up with the cloth.

7. In a rotary cloth-press, in combination, a cylinder, a presser, a non-endless apron, means whereby the cloth and non-endless apron are conducted between the cylinder and presser and means whereby said non-endless apron is wound up with the cloth after leaving said presser.

8. In a rotary cloth-press, in combination, a heated cylinder, a presser, a non-endless apron, means whereby the cloth and non-endless apron are conducted between the cylinder and presser, means whereby they are held in contact with the cylinder after passing beyond the presser and means whereby they are thereafter wound up together.

9. In a rotary cloth-press, in combination, a cylinder, a presser, means whereby the cloth is conducted between the same, a non-endless apron, and means whereby the cloth and non-endless apron are after leaving said presser held in contact with a heated surface and wound up together.

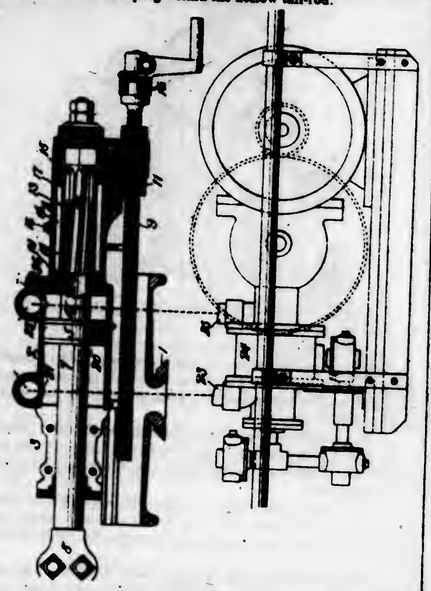
810,639. ROCK-DRILL. ARTHUR H. GIBSON, Easton, Pa., assignor to The Ingersoll-Sergeant Drill Company, New York, N. Y., a Corporation of West Virginia. Filed June 2, 1905. Serial No. 263,433.

Claim.—1. The combination with a rock-drill cylinder having a rear extension, of a piston having a hollow tail-rod extended into and entirely inclosed by said rear extension, a sleeve surrounding the tail-rod forming an annular chamber within the rear extension, a rifle-bar telescoping within the tail-rod and a port leading from the annular chamber to the air-space within the sleeve and tail-rod.

2. The combination with a rock-drill cylinder having a rear extension, of a piston having a hollow tail-rod extended into and entirely inclosed by said rear extension, a sleeve surrounding the tail-rod forming an annular chamber within the rear extension, a rifle-bar telescoping within the tail-rod, a port leading from the annular chamber to the air-space within the sleeve and tail-rod and an aperture leading from the annular chamber to the exterior.

3. The combination with a rock-drill cylinder having a rear ex-

tension, of a piston having a hollow tail-rod extended into and entirely inclosed by said rear extension, a hollow sleeve surrounding the tail-rod, a washer surrounding the tail-rod for preventing as much as possible the leakage of air past the same from the piston-chamber and a rifle-bar telescoping within the hollow tail-rod.



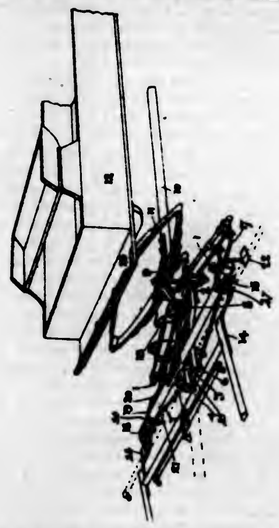
810,640. BRUSH HOLDER AND SCRAPER. CHARLES T. GREENER, Faulkton, S. D. Filed May 11, 1905. Serial No. 259,933.

Claim.—1. A device of the class described comprising spring members for attachment of the device to a pail or receptacle, the members being twisted upon themselves and joined together intermediate their ends, to form upper members for the reception of a brush-handle, a brush-wiper carried by the members, and a putty-receptacle carried by the members.

2. A device of the class described, comprising spring members whereby the device may be attached to a pail or receptacle, the spring members including clamping members and members also for the reception of a paint-brush, a brush-wiper, a putty-receptacle, the brush-wiper and the walls of the receptacle being formed of a single piece of material, and means for clamping the aforesaid members tightly upon the side wall of the pail or bucket.

3. A device of the class described comprising spring members for attachment to a pail, and having means for clamping a brush-handle therebetween, a brush-wiper, a putty-receptacle, and means for clamping the aforesaid members tightly into engagement with the inner and outer walls of the pail.

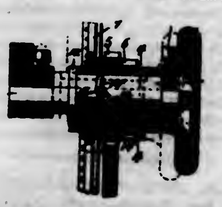
810,641. SHAFT AND POLE COUPLING FOR WAGONS. ROBERT GRUNER, Louisville, Ky. Filed Aug. 14, 1905. Serial No. 274,033.



Claim.—1. In draft-gear for wagons, the combination of the front axle, fore hounds curved upward, a transverse draft-bar secured above the front ends of said fore hounds, pillars between said fore hounds and said draft-bar, a truss-rod connecting said fore hounds with the outer ends of said draft-bar, braces connecting the outer ends of said draft-bar with the front axle, a brace connecting said draft-bar with said fore hounds, a spring-stay secured at its rear end to the perch of the wagon and at its forward end to the front part of the fifth-wheel, and a supporting-hook secured to the forward end of said spring-stay and extending under and bearing on the under surface of the lower portion of the fifth-wheel, substantially as specified.

2. In a draft-gear for wagons, the combination of a front axle, fore hounds secured to said front axle and to the fifth-wheel, a transverse draft-bar, means for securing said draft-bar to said fore hounds in elevated relation thereto, means for supporting the outer ends of said draft-bar relative to said fore hounds, means for rigidly connecting the outer ends of said draft-bar with said front axle, and means for bracing the forward part of the fifth-wheel, said fore hounds and said draft-bar from the perch and preventing torsional strain on the axle, substantially as specified.

810,642. CHANGEABLE-SPEED GEAR FOR FEEDER-APRONS. WILLIAM T. S. GOODEN, Battlecreek, Mich., assignor to Nichols and Shepard Company, Battlecreek, Mich. Filed Mar. 28, 1903. Serial No. 151,694.



Claim.—1. The combination with a driving-shaft and a driven shaft, of means for varying the relative speed of said driven shaft,

consisting of a gear-wheel on one shaft, a plurality of different-sized pinions on the other shaft adapted to mesh with said gear-wheel and a pinion-shifting device which actuates the pinions lengthwise and also laterally with respect to their shaft.

2. The combination with a driving-shaft, and a driven shaft, of mechanism for varying the relative speed of said shafts consisting of a gear-wheel on one of said shafts, connected pinions adapted to mesh therewith, and means for moving the pinions across the periphery of the gear-wheel and toward or away from the axis of the gear-wheel without varying the position of either shaft.

3. The combination with parallel driving and driven shafts, of mechanism for varying the relative speed of said shafts consisting of a gear-wheel on one of said shafts, connected pinions adapted to mesh therewith, and means for moving the pinions across the periphery of the gear-wheel and toward or away from the axis of the gear-wheel without varying the position of either shaft.

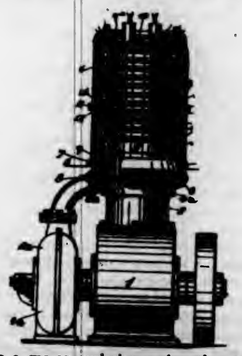
4. The combination with a driving-shaft, and a driven shaft, of mechanism for varying the relative speed of said shafts consisting of a gear-wheel on one of said shafts, connected pinions adapted to mesh therewith, an eccentric on which the pinions are journaled, and means for turning said eccentric and also moving the same endwise to carry the pinions across the periphery of the gear-wheel and also toward or away from the axis of the gear-wheel.

5. The combination with a driving-shaft, and a driven shaft, of mechanism for varying the relative speed of said shafts consisting of a gear-wheel on one of said shafts, connected pinions adapted to mesh therewith, an eccentric sleeve on which the pinions are journaled, a shaft on which the eccentric sleeve turns, means for turning the eccentric sleeve on its shaft, and means for causing said sleeve to move lengthwise of its shaft.

6. The combination with a driving-shaft, and a driven shaft, of mechanism for varying the relative speed of said shafts consisting of a gear-wheel on one of said shafts, connected pinions adapted to mesh therewith, one at a time, an eccentric sleeve on which the pinions are journaled, a shaft on which the eccentric sleeve turns, a pin on the shaft working in a spiral slot in the eccentric sleeve, and means for turning said sleeve.

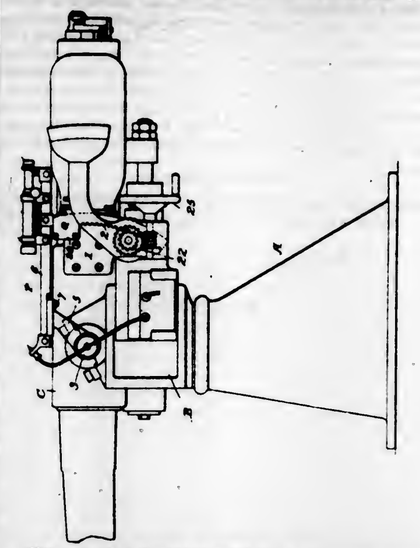
7. The combination with a driving-shaft, and a driven shaft, of mechanism for varying the relative speed of said shafts consisting of a gear-wheel on one of said shafts, connected pinions adapted to mesh therewith, one at a time, an eccentric sleeve on which the pinions are journaled, a shaft on which the eccentric sleeve turns, a pin on the shaft working in a spiral slot in the sleeve, means for turning said sleeve, and means for holding said sleeve fixed when adjusted.

810,643. COOLING MEANS FOR EXPLOSIVE-ENGINE CYLINDERS. SIMEON HAM, Indianapolis, Ind., assignor of one-half to August H. Timmerman, Indianapolis, Ind. Filed May 8, 1905. Serial No. 259,966.



Claim.—In a gas or explosive engine, the combination with the cylinder thereof and a series of integral-turned air-cooling ribs surrounding said cylinder, of a jacket or casing surrounding said cooling-ribs of said cylinder and having its top and bottom ends open, said jacket having an outwardly-flaring base-lip, an inwardly and downwardly curved deflecting-lip situated at the top of said jacket or casing whereby the column of outgoing air is deflected against the end cover of the cylinder, an annular air-jet tube, having a continuous annular slit or air-outlet jet-opening, situated beneath the bottom open end of said casing in relative position thereto so that the air under pressure escaping from said annular slit is directly applied to cool the cylinder, a pressure-blower connected directly to the crank-shaft of said engine and suitable means for connecting said blower to said annular jet-tube.

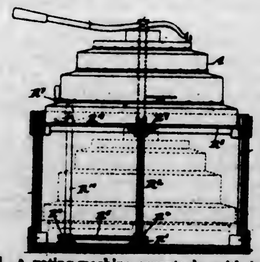
810,644. SIGHT FOR ORDNANCE. EDGAR A. S. HANHAM, South Bethlehem, Pa., assignor to Bethlehem Steel Company, South Bethlehem, Pa., a Corporation of Pennsylvania. Filed Nov. 20, 1903. Serial



Claim.—1. The combination with the top carriage and gun of a gun-mount, of a cradle swinging on the top carriage, elevating-gear supported by the top carriage and an elevating-rack connected with the cradle, a frame composed of two connected sections, one section carrying a telescope and provided with a rack, and the other section pivoted to the gun, and elevating-gear independent of the gun-elevating gear, carried by the cradle and constructed to raise and lower the said frame, substantially as set forth.

2. The combination with the swinging cradle of a gun, of a rack-plate 1 connected to the cradle, and having a curved rack 2 thereon, a swinging frame carrying a telescope and provided with a rack 15, lying alongside of the rack 2, a casing formed in part by the said plate and in part by a cap-plate 30, elevating-gear engaging the rack 15 and inclosed by said plates; and an external operating-handle for said gear, substantially as set forth.

810,645. SUPPORT FOR VOTING-MACHINES. ELIZA A. HARRINGTON, Lyndhurst, N. J., executrix of Charles F. Harrington, deceased, assignor to The Diel Voting Machine Company, Lyndhurst, N. J., a Corporation of New Jersey. Filed Feb. 1, 1905. Serial No. 243,777.



Claim.—1. A voting-machine receptacle, with interior guide-rails, a base-plate having means cooperating with said guide-rails, means for raising and lowering said base-plate comprising a central

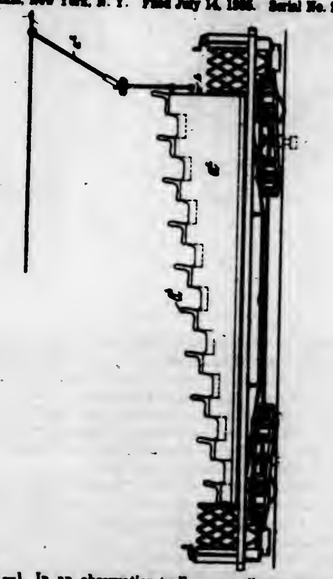
screw-shaft, extending axially of said receptacle and engaging a

3. In spacing mechanism, the combination of a stationary rack-

screw-shaft, extending axially of said receptacle and engaging a threaded boss on said base-plate, a shaft parallel with said screw-shaft, means for rotating the same, means for imparting rotary motion to the screw-shaft therefrom, and the axially-disposed tubular operating-shaft of the voting-machine inclosing the screw-shaft for guiding the voting-machine in its movements and serving to center the same with relation to said screw-shaft, all substantially as and for the purpose specified.

2. A receptacle and support for a voting-machine, comprising a case, a centrally-located screw-shaft therein, guide-rails on the interior of said case, a base-plate carrying said machine and matching said guide-rails, a screw-threaded boss on said plate receiving said screw-shaft, a driving-shaft and means for operating it, a sprocket-wheel on each of said shafts, a sprocket-chain for said sprocket-wheels, and swinging brackets hinged to said case, adapted to engage said base-plate and support the latter and the machine thereon and blocks within said receptacle upon the bottom thereof to support the base-plate and voting-machine free of the sprocket-wheels and chain.

810,646. OBSERVATION-TROLLEY-CAR RAILWAY. LOUIS J. HARRIS, New York, N. Y. Filed July 14, 1905. Serial No. 269,719.



Claim.—1. In an observation-trolley-car railway, a track, a pair of trucks movable along the track, a platform carried by the trucks, a car-body rotatably supported by the platform intermediate the said trucks, an electric conductor and a traveling contact to engage therewith.

2. In an observation-trolley-car railway, a track, a pair of trucks movable along the track, a platform supported by the trucks, a car-body rotatably supported by the platform intermediate the said trucks, means to rotate the car-body, an electric conductor and a traveling contact to engage therewith.

3. In an observation-trolley-car railway, a track, a pair of trucks movable along the track, a platform supported by the trucks, means to impart movement to the said trucks, a car-body having a series of stepped seats rotatably supported by the platform intermediate of said trucks, an electric conductor, and a traveling contact to engage therewith.

4. In an observation-trolley-car railway, a track, a pair of trucks movable along the track, a platform supported by the trucks, a car-body having a series of stepped seats and rotatably supported by the platform intermediate the said trucks, means to rotate the car-body, an electric conductor and a traveling contact to engage therewith.

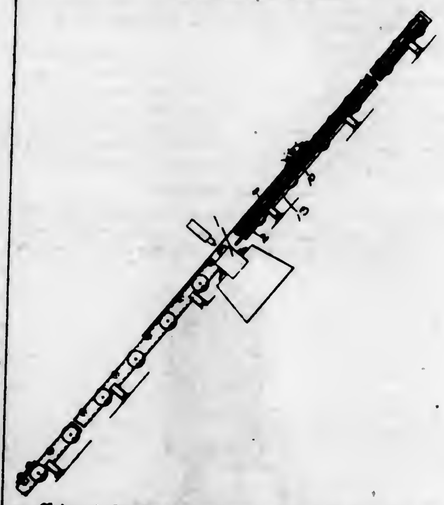
810,647. REFILLED-BOTTLE DETECTOR AND IDENTITY-DESTROYER. EDWIN S. HAYNES, Boston, Mass. Filed July 17, 1905. Serial No. 269,932.

Claim.—1. The combination with a bottle, of a sealing-plug secured within the neck of the bottle and having a weakened portion below the top of the neck, substantially as described.

2. The combination with a bottle, of a sealing-plug having a tubular portion secured within the neck of the bottle, an expanded upper end of substantially the diameter of the neck of the bottle, and a weakened portion located below the top of the neck, substantially as described.

3. The combination with a bottle, of a tubular sealing-plug having a weakened portion, and a stopper secured within the plug and extending above the weakened portion, substantially as described.

810,648. SPACING MECHANISM. WILLIAM L. HAYNES, Ambridge, Pa. Filed Oct. 26, 1904. Serial No. 229,127.



Claim.—1. In spacing mechanism, the combination of a stationary spacing-bar, a bar parallel to said spacing-bar, a spacing-stop member movable along said spacing-bar, and changeable stop-pieces adapted to be inserted between said bars and held with their ends projecting into position to be engaged by said stop member, said spacing-bar and stop-pieces being provided with equidistant co-operating depressions and projections, and said stop-pieces having a stop-face on each end arranged differently with reference to their projections.

2. In spacing mechanism, the combination of a stationary spacing-bar, a spacing-stop member movable along said bar, changeable stop-pieces adapted to be held by said bar in position to be engaged by said stop member, said bar and stop-pieces being provided with equidistant co-operating depressions and projections, and said stop-pieces having a stop-face on each end arranged differently with reference to their projections, and having both end faces cleared away back of said stop-faces.

3. In spacing mechanism, the combination of a stationary rack-bar, a bar parallel to said rack-bar, a spacing-stop member movable along said rack-bar, and changeable stop-pieces provided with teeth and adapted to be inserted between said bars and held by said rack with their ends projecting into position to be engaged by said stop member, said stop-pieces having a stop-face on each end arranged differently with reference to their teeth.

4. In spacing mechanism, the combination of a stationary rack-bar, a spacing-stop member movable along said bar, and changeable stop-pieces provided with teeth and arranged to be engaged by said rack and held in position to be engaged by said stop member, said stop-pieces having a stop-face on each end and having both ends cleared away behind said stop-faces.

5. In spacing mechanism, the combination of a stationary rack-bar, a bar parallel to said rack-bar, a spacing-stop member movable along said rack-bar, and changeable stop-pieces provided with teeth for engaging the rack and adapted to be inserted between said bars and held with their ends projecting into position to be engaged by said stop member, said stop-pieces having stop-faces on their ends, and one of said bars being provided with a ledge or flange against which the end of the stop-pieces abut.

6. In spacing mechanism, the combination of a stationary rack-bar, a spacing-stop member movable along said bar, changeable stop-pieces provided with teeth for engaging the rack and adapted to be held by the latter in position to be engaged by the stop member, said stop-pieces being provided with a stop-face at each end and having their ends cleared away back of said stop-faces, and means for holding said stop-pieces against said rack-bar.

7. In spacing mechanism, the combination of a stationary spacing-bar, a spacing-stop member movable along said bar, changeable stop-pieces adapted to be held by said bar in position to be engaged by said stop member, a bar parallel to the spacing-bar and arranged to hold the spacing-pieces against the spacing-bar, said spacing-bar and holding-bar being provided with teeth on their facing sides, and said stop-pieces being provided on their side faces with corresponding teeth.

8. In spacing mechanism, the combination of a stationary spacing-bar, a bar parallel to said spacing-bar, said spacing-bar being provided with teeth on its side which faces the other bar, a spacing-stop member movable along said bars, and changeable stop-pieces adapted to be inserted between said bars and provided on their side faces with teeth to engage the teeth on said spacing-bar.

9. In spacing mechanism, the combination of two parallel bars both provided with teeth on their facing sides, a spacing-stop member movable along said bars, and changeable stop-pieces provided with teeth on two of their sides and adapted to be inserted between said bars and held in position thereby to be engaged by said spacing member.

10. In spacing mechanism, the combination of a stationary spacing-bar, a spacing-stop member movable along said bar, changeable stop-pieces adapted to be held by said bar in position to be engaged by said stop member, a hinged clamping-bar parallel to the spacing-bar, and means for pressing the same against said spacing-pieces.

11. In spacing mechanism, the combination of a stationary spacing-bar, a spacing-stop member movable along said bar, changeable stop-pieces adapted to be held by said bar in position to be engaged by said stop member, a clamping-bar parallel to the spacing-bar and movable toward and from the same, and fluid-pressure means for moving the same.

12. In spacing mechanism, the combination of a stationary spacing-bar, a spacing-stop member movable along said bar, changeable stop-pieces adapted to be held by said bar in position to be engaged by said stop member, a clamping-bar parallel to the spacing-bar, a stationary abutment at the side of said clamping-bar, and an expansible fluid-pressure chamber between said clamping-bar and stationary abutment.

13. In spacing mechanism, the combination of a stationary spacing-bar, a spacing-stop member movable along said bar, changeable stop-pieces adapted to be held by said bar in position to be engaged by said stop member, a clamping-bar parallel to the spacing-bar and movable toward and from the same, a spring and fluid-pressure means, the one for moving said clamping-bar toward the spacing-bar, and the other for moving the same away from said spacing-bar.

14. In spacing mechanism, the combination of a stationary spacing-bar, a spacing-stop member movable along said bar, a clamping-bar parallel to the spacing-bar, said clamping and spacing bars being provided on their facing sides with teeth, changeable stop-pieces provided with teeth on opposite side faces for engaging the teeth in the clamping and spacing bars, and means for moving said clamping-bar to clamp said spacing-pieces against the spacing-bar.

15. In spacing mechanism, the combination of a stationary rack-bar, and a series of changeable stop-pieces having teeth on two of their sides for engaging said rack-bar and having stop-faces on opposite sides thereof, whereby said stop-pieces are reversible.

16. In spacing mechanism, the combination of a stationary rack-bar, and a series of changeable stop-pieces adapted to be held by said rack-bar, said stop-pieces having teeth on opposite side faces and with stop-faces on opposite edge faces and having a portion of each side face cleared away back of the two stop-faces.

17. In spacing mechanism, the combination of a stationary rack-bar, and a series of changeable stop-pieces adapted to be held by said rack-bar, said stop-pieces being provided with teeth on two opposite side faces and with stop-faces on the two opposite edge faces at both ends, whereby said stop-pieces are reversible end for end and side for side.

18. In spacing mechanism, the combination of a stationary rack-bar, and a series of changeable stop-pieces adapted to be held by said rack-bar, said stop-pieces being provided with teeth on the two opposite side faces and with stop-faces on the two opposite edge faces at both ends and having both side faces at both ends cleared away back of said stop-faces.

19. In spacing apparatus, a stationary bearing having vertical serrations therein, a movable bearing having vertical serrations therein, a stop having vertical serrations engaged by the serrations of said bearings, and means for clamping said parts together.

20. In spacing apparatus, a reversible stop having contact-surfaces on opposite ends thereof unequally distant from the plane parallel thereto and passing centrally through the body of said stop, a stationary bearing and a movable bearing for clamping said stop.

21. In spacing apparatus, a stop having parallel serrations on opposite sides thereof and opposite ends having contact-surfaces unequally distant from the axial plane of said stop.

22. In spacing apparatus, a series of adjustable stops, a bar for holding said stops, and mechanism for clamping several points of said bar by a single operation.

23. In spacing apparatus, a series of adjustable stops, a stationary bearing having serrations thereon, a movable bearing having serrations thereon, a plurality of stops having serrations engaged by the serrations of said bearings, and mechanism for clamping and unclamping said parts at several points by a single operation.

24. In spacing apparatus, a series of adjustable stops and mechanism for fastening or unfastening all of said stops by a single operation.

810,649. WHEEL. CHARLES HEART, Alexandria, Ind., assignor to Heart Metal Wheel and Gear Company, Alexandria, Ind., a Corporation of Indiana. Filed May 26, 1905. Serial No. 262,114.

Claim.—1. A wheel including a hub having a body comprising two parts, two shell parts embracing the body parts and provided with projections forced into ends of the body parts, a spoke-seat arranged between the opposing ends of the shell parts, a plurality of spokes seated against the spoke-seat, a felly attached to the spokes, and means forcibly holding the spokes between the opposing ends of the shell.

2. A wheel including a hub having a body comprising two parts provided each with an inclosing shell having a circular hub-seat attached thereto and telescoping one with another, a plurality of spokes engaging one of the hub-seats, a felly attached to the spokes, and means engaging the shells of the two parts of the hub-body and forcing the same against opposite sides of the plurality of spokes.

3. A wheel including a hub comprising two companion parts, each part composed of a body part, a shell embracing the body part and secured thereto, and a flanged casing embracing the shell, one shell having a circular spoke-seat attached thereto and to the body part; a plurality of spokes engaging the spoke-seat, means engaging the casings and forcing the shells therewith against opposite sides of the plurality of spokes, and a felly attached to the plurality of spokes.

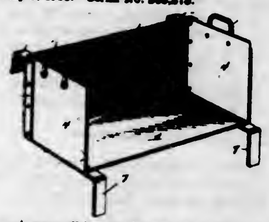
4. A wheel including a hub comprising two companion parts, each part composed of a body part, a shell embracing the body part

and having flanges at opposite ends thereof turned over portions of the ends of the body part, the shell being secured to the body part, each shell having a circular flanged spoke-seat attached thereto and to the body part by means of a flange of the shell and the flange of the spoke-seat, a plurality of spokes engaging the spoke-seat, a felly attached to the plurality of spokes, and means engaging the shells and thereby forcing the two companion parts of the hub against opposite sides of the plurality of spokes.

5. A wheel including a hub comprising two companion parts, each part composed of a body part of which one part has a projection at an end thereof, a shell embracing the body part and having flanges at ends thereof turned over portions of the ends of the body part, the shell being secured to the body part, each shell having a circular flanged spoke-seat attached thereto and to the body part by means of the flanges thereof, one of the spoke-seats extending over the projection of the body part and into the other spoke-seat, a plurality of spokes engaging one of the spoke-seats, a felly attached to the plurality of spokes, and a flanged casing attached to the shell; and means engaging the casings of the two companion parts and forcibly holding the plurality of spokes between the two companion parts of the hub.

6. A wheel including a hub comprising two companion parts, each part composed of a conical wooden body part, a conical metallic shell embracing the body part and having a flange at the larger end thereof turned over a portion of the larger end of the body part and also having a flange at the smaller end thereof provided with projections forced into the smaller end of the body part, the shell having a circular spoke-seat having a flange extending between the larger end of the body part and the turned-over flange of the shell, the spoke-seat of one part extending about the spoke-seat of the other part and movable thereon, a plurality of spokes engaging the outer one of said spoke-seats, a felly attached to the plurality of spokes, casings attached to the companion parts, means securing the casings and the companion parts against the plurality of spokes, and an axle-box in the body parts of the hub.

810,650. IRON-HEATER. MARTHA G. HENDLEY, Mayfield, Ky. Filed July 3, 1905. Serial No. 268,573.

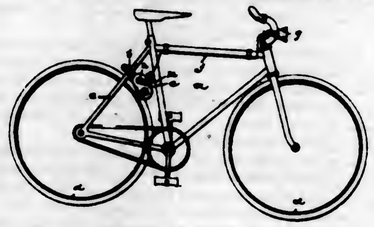


Claim.—A reversible attachment for stoves comprising a body formed of sheet metal and consisting of integral main walls disposed at right angles to each other and both adapted to be utilized either as a shelf or a heating-wall, end walls integral with one of the main walls and flanges integral with the ends of the other one of the main walls and overlapping and permanently connected to the end walls, flat metal strips permanently connected to the main walls adjacent their ends and terminating at one end in legs and at the other end in hooks, either the legs or hooks being adapted to project through a grate and into fuel to support the heating attachment in contact with the grate, and handles extending from the end walls.

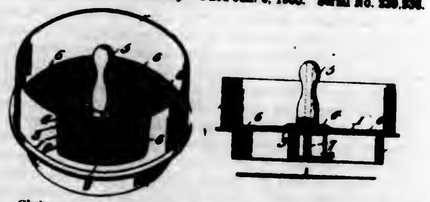
810,651. ELECTRIC GENERATOR FOR BICYCLES. FRANK X. HEDBAUER, West Orange, N. J. Filed June 14, 1902. Serial No. 111,897.

Claim.—1. The combination with the bicycle-frame and running-wheel, the former having a pivotal arm and holding-spring, of a dynamo-electric machine arranged on said pivotal arm and adapted to engage the running-wheel of the bicycle and be operated thereby and adapted to engage said holding-spring and be held thereby out of operative relation to said running-wheel, the dynamo being provided with a box-like protuberance serving the double purpose as a receptacle for contacting conducting devices of the dynamo and as an arm or protuberance to engage the holding-spring, substantially as set forth.

2. The combination with the headlight and conducting-wires, of a dynamo-electric machine comprising a magnet, non-magnetic side plates, an armature rotating between said side plates, between the prongs of the magnet, the said side plate furnishing bearings for a pivotal arm and a box-like protuberance, a contact-spring in said protuberance engaging the armature-shaft and conductors of said magnet and spring with said headlight, substantially as set forth.



810,652. SIEVE. WILLIAM H. HOTT and WILLIAM J. GAVEN, Bridgeport, Conn., assignors to The Burt Company, Hackensack, N. J., a Corporation of New Jersey. Filed Jan. 6, 1905. Serial No. 239,936.



Claim.—1. In a sieve, the combination of a clearing device, means for confining the deposit of material to the desired surface, means for centering the sieve over said surface, and means for protecting a portion of said surface from the deposit of material thereon.

2. In a sieve, the combination of a clearing device, means for confining the deposit of material to the desired surface, means for centering the sieve over said surface, and means resting on said surface and protecting a portion thereof from the deposit of material thereon.

3. In a sieve, the combination of the wire mesh, a clearing device, means for confining the deposit of material to the desired surface, means for centering the sieve over said surface, and a cylinder secured to the center of the under side of the wire mesh to protect a portion of said surface from the deposit of material thereon.

4. In a sieve, the combination of the wire mesh, a clearing device, means for centering the sieve over the surface on which material is to be deposited, and a cylinder secured to the center of the under side of the wire mesh to protect a portion of said surface from the deposit of material thereon.

5. In a sieve, the combination of the wire mesh, a clearing device, a cylinder secured to the center of the under side of the wire mesh to protect a portion of the surface on which the material is to be deposited, and means arranged within said cylinder for centering the sieve over said surface.

6. In a sieve, the combination of the wire mesh, a clearing device, a cylinder secured to the center of the under side of the wire mesh to protect a portion of the surface on which the material is to be deposited, and a guide in the center of the cylinder for centering the sieve over the desired surface.

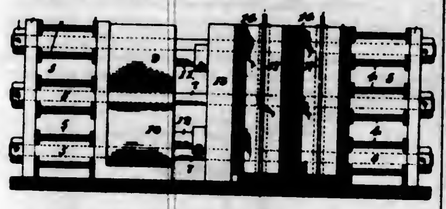
7. In a sieve, a foraminous material constituting the sieve proper, and means carried thereby and confining to an annular space the material deposited by said sieve.

810,653. GAS-BURNER. SAMUEL W. HYATT, Mount Vernon, Ohio. Filed Jan. 14, 1905. Serial No. 241,004.

Claim.—A gas-burner comprising a nozzle provided with a port, a valve having a stem of less cross diameter throughout than the port and adapted to project therethrough and having its tip cut away to provide a gas-escape, means for adjusting the parts with relation

to each other, and means for holding the parts in their adjusted positions.

810,654. INGOT-CASTING MACHINE. JOHN ILLINGWORTH, Newark, N. J. Filed June 17, 1905. Serial No. 265,749.



Claim.—1. In an ingot-casting machine, side walls or frames comprising I-beams arranged horizontally one upon another, tie rods or bolts binding the said side walls together, a hydraulic cylinder and a piston, and a mold arranged between the piston and one of the side walls, said mold being in sections disposed perpendicular to the direction of movement of the said piston and having pieces separably inserted between the sections and adapted to be wholly withdrawn from between the molds preliminary to a compression of the partially-cooled ingot.

2. In an ingot-casting machine, the combination of opposite side walls, each comprising a series of I-beams arranged horizontally upon one another, tie rods or bolts holding said side walls together, a series of molds arranged transversely of the machine between two adjacent tie-rods, and a hydraulic cylinder and piston also between said tie-rods in series with said molds, the said molds each being in sections disposed perpendicular to the direction of movement of the said piston and each having pieces also disposed in lines perpendicular to said movement of said piston, said pieces being separable from the sections of the mold and adapted to be wholly withdrawn endwise from between said sections preliminary to the compressing action of the hydraulic piston.

3. In an ingot-casting machine, the combination with a bed-plate, opposite side walls each comprising a vertical series of horizontally-disposed I-beams, transverse tie rods or bolts holding the said side walls together, a transverse series of molds arranged between two adjacent tie-rods, a loose base-plate beneath said molds, a pressure-piece against the side of said molds farthest from the side wall, and a hydraulic cylinder and piston between said pressure-piece and the other side wall, the said molds being each in sections having therebetween removable pieces disposed transversely to the direction of movement of the piston and adapted to be withdrawn from between said sections preliminary to the compressing operation of the hydraulic piston.

4. In an ingot-casting machine, a mold comprising a body portion divided longitudinally into sections and having the meeting edges of said sections grooved, tongued metallic filler-pieces adapted to be inserted between said edges and lie in said grooves and means for compressing said molds.

5. In an ingot-casting machine, a series of molds each comprising a tubular body portion divided longitudinally into sections, the opposing edges of said sections being grooved and filler-pieces each adapted to lie between two meeting edges of the mold-sections and having opposite tongues to enter the grooves of said edges, and means for compressing said molds.

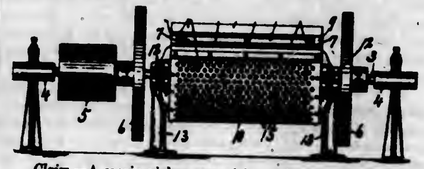
6. In an ingot-casting machine, a frame having opposite side walls, a series of molds arranged between said side walls, each mold being divided longitudinally into sections, filler-pieces adapted to be inserted between the edges of said sections and wholly withdrawn from therebetween preliminary to the compressing operation and means for compressing said molds.

7. In an ingot-casting machine, the combination of molds, each comprising longitudinal sections adapted to meet at their edges, and having said edges grooved, filler-pieces each comprising a body portion adapted to lie between the meeting edges of the mold-sections, and projecting upwardly beyond the upper ends of said sections and thereat provided with a handle whereby the filler-piece may be withdrawn longitudinally and wholly from between said sections and having at its opposite sides below said handle ribs or tongues to enter the grooves of said edges.

8. The improved ingot-forming machine herein described, having therein a mold in sections, the contiguous walls of which are grooved and have filler-pieces inserted between said contiguous walls and provided with ribs to enter said grooves, substantially as set forth.

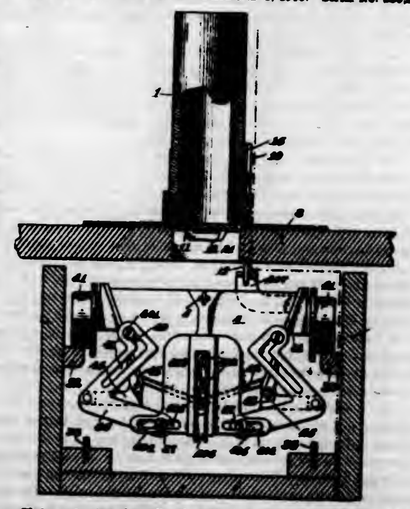
9. The improved ingot-forming machine herein described, comprising two vertical series of beams and means for holding said beams together in series and means for tying one series to the other series, the said series being one at a distance from the other, spaces being provided between said series to receive a collection of sectional molds and a plurality of hydraulic rams, the said rams bearing against one wall of the series of beams and oppositely against certain of the sectional molds, pieces inserted, perpendicular to the direction of movement of the hydraulic rams, between the sections of the molds and adapted to be removed from between said molds, substantially as set forth.

810,655. CASEIN-PICKER. A. B. IRELAND, Greene, N. Y. Filed July 20, 1904. Serial No. 218,571.



Claim.—A casein-picker comprising a sheet-metal shell having an inlet in one side and having an angle-plate arranged at each edge of said inlet, said shell being provided with a series of holes extending throughout the entire surface of the shell, portions of the stock around each hole being left integral with the shell and pressed inwardly beyond the inner surface of the shell to form pickers, supports for said shell, a shaft journaled in said supports, radial arms carried by said shaft and flat bars connected to the outer ends of said radial arms and forming a dasher.

810,656. COIN COLLECTING AND CARRYING DEVICE. MORRIS KOHN, New York, N. Y. Filed Jan. 3, 1905. Serial No. 239,327.



Claim.—1. A coin-collecting device comprising a coin-chute, coin-retaining means at the foot of said chute, a dump-car traveling beneath said chute, a coin-receptacle in the line of travel of said car, means on said car for first unlocking and then tripping said coin-retaining means, and means for dumping coins carried by said car into said receptacle.

2. A coin-collecting device, comprising a coin-chute, coin-retaining means at the foot of said chute, a car having normally locked dumping means traveling beneath said chute, a coin-receptacle in the line of travel of said car, means on said car for tripping said coin-retaining means, and means for first unlocking and then tripping said dumping means.

2. A coin collecting and distributing device comprising a coin-holder, toggle-acting levers connected to operate the holder, a car below said coin-holder having two bottom doors, a member on said car cooperating with one of the members of the toggle on the said coin-holder, each bottom door of said car being pivoted at its side and made to cover half the bottom of the car, a side extension to each bottom door, toggle-acting means connected to operate the doors by means of said side extension, and a cam below said car made to cooperate with the toggle-acting means on the car.

4. A coin-collecting device comprising a coin-holder, toggle-acting levers connected to operate the holder, a car below said coin-holder, and a member on said car cooperating with one of the members of the said toggle, whereby the coin-holder is tripped as the car passes under the coin-holder.

5. A coin collecting and distributing device comprising a car having two bottom doors, each bottom door pivoted at its side and made to cover half the bottom of the car, a side extension to each bottom door, toggle-acting means connected to control the doors by means of said side extension, and a cam below said car made to cooperate with the toggle-acting means, whereby the doors are tripped as the car passes over the cam.

6. A coin-collecting device comprising a coin-holder, toggle-acting levers connected to operate the holder, means for locking said holder in its normal position, a car below said coin-holder, and a member on said car cooperating with one of the members of the said toggle, whereby the coin-holder is unlocked and tripped as the car passes under the coin-holder.

7. A coin collecting and distributing device comprising a car having two bottom doors, each bottom door pivoted at its side and made to cover half the bottom of the car, a side extension to each bottom door, toggle-acting means connected to control the doors by means of said side extension, means for locking said doors in their normal position, and a cam below said car made to cooperate with the toggle-acting means, whereby the doors are unlocked and tripped as the car passes over the cam.

8. A coin-collecting device comprising a coin-holder, adapted to swing on a pivot, a bent lever provided with a slot and pivotally attached to the rearward extension of the holder, a pin above said holder engaging said slot, a car below said coin-holder, and a cam on said car cooperating with the bottom of the bent lever, thereby operating the coin-holder.

9. A coin-collecting device comprising a coin-holder, adapted to swing on a pivot, a bent lever provided with an angular slot and pivotally attached to the rearward extension of the holder, a pin above said holder engaging said angular slot, a car below said coin-holder, and a cam on said car cooperating with the bottom of the bent lever, thereby operating the coin-holder.

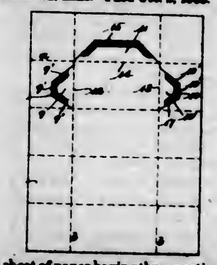
10. A coin collecting and distributing device comprising a car, a pointed bottom to said car consisting of two bottom plates, each bottom plate pivoted at its side and made to cover half the bottom of the car, a side extension to each bottom plate, bent levers each provided with an angular slot and pivotally attached to the ends of said side extensions, pins on said car above said bottom plates engaging the angular slots in the bent levers, a front plate provided with one vertical and two horizontal slots, means on said car engaging the vertical slot for holding said front plate, whereby a certain vertical movement is permitted, a pin on each of the said bent levers engaging the horizontal slots of the said front plate, a wheel in said vertical slot, and a cam below said car made to cooperate with the said wheel on the said front plate to force the said front plate up, thereby operating the bottom plates.

11. A coin collecting and distributing device comprising a car, a bottom to said car composed of two bottom plates, each bottom plate pivoted at its side and made to cover half the bottom of the car, a sidewardly extension to each bottom plate, bent levers each provided with a slot and pivotally attached to the ends of said side extensions, pins on said car above said bottom plates engaging the slots in the bent levers, a front plate provided with one vertical and two horizontal slots, means on said car engaging the vertical slot for holding said front plate, whereby a certain vertical movement is permitted, a pin on each of the said bent levers engaging the horizontal slots of the said front plate, a wheel in said vertical slot, and a cam below said car made to cooperate with the said wheel on the said front plate to force the said front plate up, thereby operating the bottom plates.

810,657. WRENCH. FRANK KNOX, Gatewood, S. D. Filed Sept. 23, 1905. Serial No. 279,324.

Claim.—A wrench consisting of a fixed shank having a stationary jaw at one end and a gaby at its other end said grip having a recess therein parallel with the fixed shank, a jaw slidably mounted upon the fixed shank, a movable shank extending from the slidable jaw and projecting longitudinally of the fixed shank and having teeth upon its inner face, a dog extending through the fixed shank and normally engaging the teeth on the movable shank, a shoulder upon the dog, a bow-spring within the recess and retained by the shoulder, said spring holding the dog normally in engagement with the teeth, said dog extending into close proximity to the grip and a thumb-piece upon the movable shank, said dog and thumb-piece extending in opposite directions from their shanks and adapted to be simultaneously engaged by members of a hand holding the grip.

810,658. COMBINED REVELOP AND LETTER-PAPER. ABNER B. HASCOM, Brentwood, Mass. Filed Oct. 2, 1905. Serial No. 280,867.



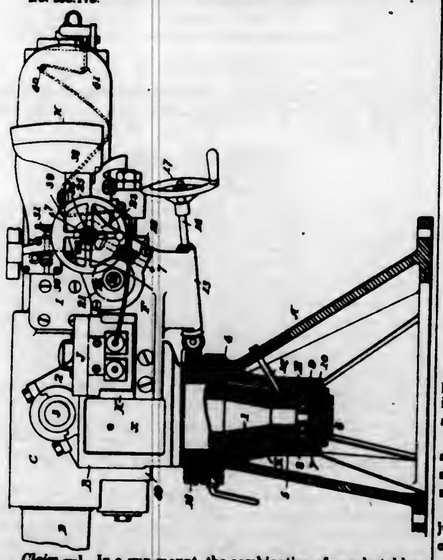
Claim.—1. A sheet of paper having three portions cut out to form three openings, each of said portions thus cut out remaining attached at one side thereof to said sheet, two of said portions having their attached sides parallel to each other and constituting end flaps, the third portion having its attached side substantially at right angles to the attached sides of said end flaps, extending from one to the other and constituting a sealing-flap, said flaps adapted to be folded over and secured to said sheet when certain portions of said sheet are folded over upon each other.

2. A sheet of paper having three portions cut out to form three openings, each of said portions thus cut out remaining attached at one side thereof to said sheet, two of said portions having their attached sides parallel to each other and constituting end flaps, the third portion having its attached side substantially at right angles to the attached sides of said end flaps, extending from one to the other and constituting a sealing-flap, whereby said sheet is adapted to be first folded transversely thereacross in alinement with the attached side of said sealing-flap; second, the two sides of said sheet folded longitudinally thereof toward eachother in alinement with the attached sides of said end flaps; third, said folded sheet again folded transversely thereof parallel to the attached side of said sealing-flap, fourth, said folded sheet again folded transversely thereof parallel to the attached side of said sealing-flap and finally said flaps turned over and secured to the folded portion of said sheet.

810,659. WIRE-STRETCHER. BERNARD MARENT, Hays, Kans. Filed Mar. 9, 1905. Serial No. 249,393.

Claim.—A wire-stretcher comprising a lever having a handle; an integral curved post-engaging extension at one end and having integral ratchet-teeth thereon for successively automatically engaging the tightened portion of a wire during the stretching operation, and means for adjustably securing the loose portion of a wire to the lever between the extension and the handle.

810,660. GUN-MOUNT. JOHN F. METZ and EDGARD A. S. HASKAR, Bethlehem, Pa., assignors to Bethlehem Steel Company, South Bethlehem, Pa., a Corporation of Pennsylvania. Filed Jan. 7, 1903. Serial No. 138,175.



Claim.—1. In a gun-mount, the combination of a pedestal having a depending sleeve, cylindrical bushings therein, an elevating-plug adapted to screw into the lower end of said sleeve, and a yoke-piece having a pivot adapted to said bushings and supported by said plug, substantially as set forth.

2. In a gun-mount, the combination of a pedestal having an internal depending sleeve, cylindrical bushings therein, an elevating-plug screwing into the lower end of said sleeve, a yoke-piece having a pivot adapted to said bushings and supported by said plug, and ball-bearings between said plug and pivot, substantially as set forth.

3. The combination with the yoke-piece, of a bracket F having an arm with bearings for a traverse-shaft, and an arm recessed to form part of a gear-case, substantially as set forth.

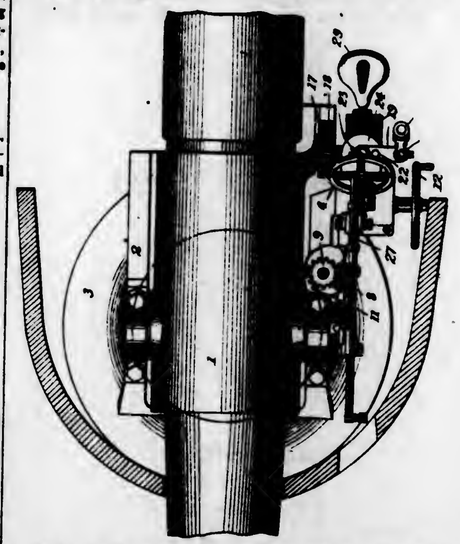
4. The combination with the yoke-piece, of a bracket F, and a cap-plate, the bracket and cap-plate being recessed to form a gear-casing and shaft-bearings for the elevating devices, said devices comprising a shaft extending transversely of said bracket and plate and engaging with a shaft located between said bracket and plate and extending parallel thereto, substantially as set forth.

5. The combination in a top carriage, of a yoke-piece, a bracket secured thereto, a cap-plate, and means for securing it to the bracket, the bracket and cap-plate recessed to receive the elevating-gear and to constitute bearings for the shafts thereof, substantially as set forth.

6. The combination of the yoke-piece, cradle, a plate carrying an elevating-rack connected to the cradle, and a detachable bracket carrying inclosed elevating-gearing connected to the yoke, substantially as set forth.

7. The combination with the yoke-piece, of a rack-plate I, having a rack 29 and recess y, and a cap-plate 30 recessed and covering the recess y to form a gear-chamber for the sight-elevating gear, substantially as set forth.

810,661. GUN-MOUNT. JOHN F. METZ and EDGARD A. S. HASKAR, South Bethlehem, Pa., assignors to Bethlehem Steel Company, South Bethlehem, Pa., a Corporation of Pennsylvania. Filed Sept. 16, 1903. Serial No. 173,405.



Claim.—1. The combination with a gun and its carriage, of a post laterally adjustable with respect to the carriage, means for locking said post in different positions, and a shoulder-brace vertically adjustable upon said post.

2. The combination with a gun and its carriage, of a swinging support, a post mounted upon said support, means for locking said support in different positions, and a shoulder-brace adjustably mounted on said post.

3. The combination with a gun and its carriage, of a seat adjustably mounted on the carriage, and a shoulder-brace also mounted on said carriage and adjustable relatively to said seat.

4. The combination with a gun and its carriage, of elevating and depressing mechanism mounted on the carriage, and a shoulder-brace having both lateral and vertical adjustment relative to said mechanism.

5. The combination with a gun and its carriage, of sighting devices mounted on said gun, and a seat and shoulder-brace, said seat and shoulder-brace being each mounted on the carriage and adjustable relatively to said sighting devices.

810,662. BALANCING MECHANISM FOR GUNS. JOHN F. METZ, South Bethlehem, and HERMAN G. JAMESON and FRANK A. SULLIVAN, Bethlehem, Pa., assignors to Bethlehem Steel Company, South Bethlehem, Pa., a Corporation of Pennsylvania. Filed Sept. 16, 1903. Serial No. 173,181.

Claim.—1. The combination with a gun and a cradle in which said gun is free to slide longitudinally, of means for adjusting the gun to any desired normal position relative to the cradle.

2. The combination with a gun and a cradle in which said gun

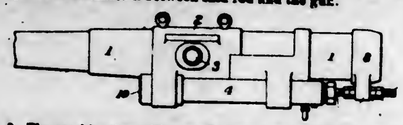
is free to slide longitudinally, of a recoil-cylinder connected with the cradle, a rod movable in said cylinder and projecting therefrom, and

mounted therein and formed of interlocking metallic strips constituting side and end bars, a pulley rotatably mounted

Claim.—The combination with a butter-working table having

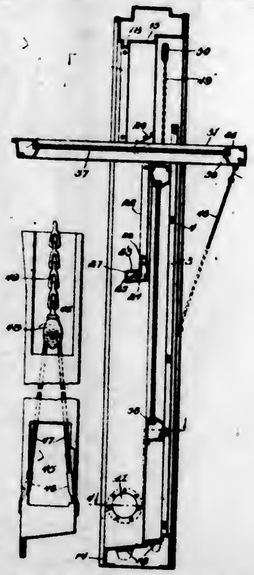
supplying oil to the upper end of said cylinder, and to the lower end

in free to slide longitudinally, of a recoil-cylinder connected with the cradle, a rod movable in said cylinder and projecting therefrom, and an adjustable connection between said rod and the gun.



3. The combination with a cradle and a gun movable longitudinally therein, of a recoil-cylinder connected with the cradle, a piston in said cylinder, a piston-rod projecting from the cylinder and provided with a threaded portion, a bracket on the gun through which said threaded rod passes, and adjusting-nuts on said rod on both sides of said bracket, whereby the gun may be adjusted relatively to said rod.

810,663. SHEET-METAL FIREPROOF WINDOW. WILLIAM H. MILLER, Galveston, Tex. Filed Apr. 17, 1905. Serial No. 255,906.



Claim.—1. The combination with a metallic window-frame comprising interlocking inner and outer strips, of slots within the sides of the frame, boxes in said frame registering with and closing the slots, a swinging sash within the frame, and bearing-pins adjustably connected thereto and detachably mounted within the slots and boxes.

2. The combination with a window-frame formed of interlocking metallic strips and normally closed apertures in the sides of the casing, said sides having guide-shoulders; of a detachable guide-strip parallel with the shoulder, a metallic sash slidably mounted between the strip and shoulder, a counterbalance, a flexible device extending from the counterbalance through the frame and into the sash, a pulley within the sash and connected to said device, a non-fusible cord mounted upon the pulley and fusible connections between the ends of the cord and the sash, said connections extending through the walls of the sash.

3. The combination with a window-frame comprising interlocking metallic strips and longitudinally-extending shoulders formed by the sides of the frame upon the inner surfaces thereof, of an intermediate metallic cross-bar connecting the sides of the frame, a stop-bead integral therewith, stop-strips upon the sides of the frame alining with said bead, a bead upon the top of the frame and depending therefrom, stop-strips upon the side of the frame alining with said bead, a sash pivoted within the frame between the stop-strips and adapted to contact therewith when opened or closed, and bearing-pins adjustably connected to the sash and engaging the frame.

4. The combination with a window-frame, of a sash movably mounted therein and formed of interlocking metallic strips constituting side and end bars, a pulley within each of the side bars, a counterbalance within the frame, flexible devices connecting the counterbalance and pulleys, non-fusible cords mounted upon the pulleys and within the sash, fusible tips connecting the ends of the cords to the sash, said tips extending through the walls of the sash, each tip being of greater thickness than the opening through the pulley.

5. The combination with a window-frame, of a sash movably mounted within the frame, a counterbalance therefor, a fusible connection between the counterbalance and sash, and means for retarding the movement of the sash subsequent to its release from the counterbalance.

6. A window-sash comprising outer and inner interlocking metallic strips forming hollow sides and end bars, said side bars having elongated apertures therein, fusible tips extending through the front and rear walls of the bars, a pulley within each side bar, a non-fusible cord mounted upon the pulley and secured at its ends to the tips, said tips being of greater thickness than the diameter of the passage through the pulley to constitute stops.

7. The combination with a window-frame; of a sash movably mounted within the frame, a counterbalance therefor, and a fusible connection between the counterbalance and sash, said connection being disposed upon one outside face of the sash.

8. The combination with a window-frame; of a sash movably mounted within the frame, a counterbalance therefor, and fusible connections between the counterbalance and sash, said connections being disposed upon opposite outer faces of the sash.

9. The combination with a metallic window-frame; of a swinging metallic sash mounted within the window-frame, a sliding sash within the frame, independent means for holding both of the sashes in opened position, and fusible connections between said means and their respective sashes, said connections being disposed outside of the sashes.

810,664. ATTACHMENT DEVICE FOR ELECTRIC CONDUCTORS. DAVID B. MILLS, East Orange, N. J. Filed Apr. 13, 1905. Serial No. 255,206.

Claim.—1. An attachment device for electrical conductors comprising a ferrule with an opening in its wall, a terminal with an opening coincident with the opening in the wall of the ferrule, and a hollow riveting means uniting them adapted to permit the passage of an electrical conductor through the opening in the two parts.

2. An attachment device for electrical conductors comprising a ferrule with an opening in its wall, a terminal with an opening coincident with the opening in the wall of the ferrule, a hollow separate rivet uniting them, adapted to permit the passage of an electrical conductor through the opening in the two parts.

3. An attachment device for electrical conductors comprising a ferrule with an opening in its wall, a terminal portion secured to said ferrule, a hollow rivet passing through the terminal portion and ferrule adapted to unite them, in combination with an electrical conductor passing through the opening in the hollow rivet and soldered in place.

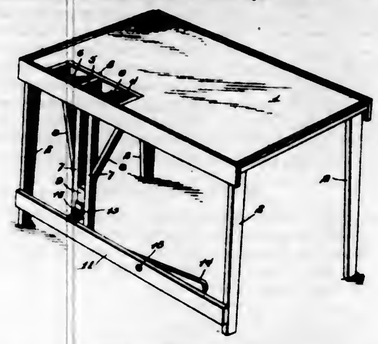
4. An attachment device for electrical conductors comprising a ferrule, of a size adapted to snugly fit the insulation part surrounding an electrical conductor, the ferrule having an opening in its wall, an attachment terminal also with an opening, a hollow riveting means passing through said openings, adapted to permit the passage of a conductor whereby the conductor may be electrically secured upon the outer part of the device.

5. An attachment device for electrical conductors comprising a metal ferrule, of a size adapted to snugly fit the insulation surrounding an electrical conductor, and provided with an opening in its end, a terminal piece with a like opening and a hollow riveting means passing through said two openings, the conductor within the insulation being adapted to be passed through the opening thus formed and secured to the exterior of the device.

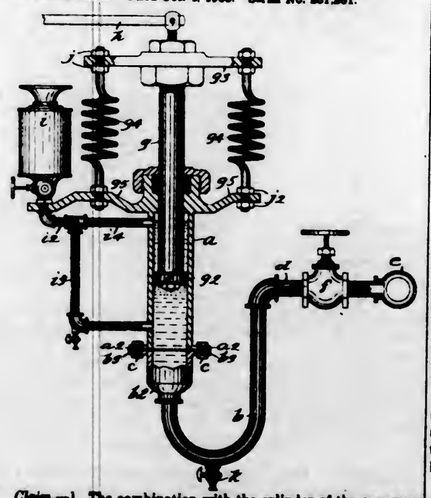
6. An attachment device comprising a cylindrical metal ferrule with an opening at one end, and a terminal piece with a bent end, said bent end secured to the end of the ferrule by a hollow rivet passing through the terminal piece and ferrule, an electrical conductor passing through the hollow rivet and soldered in the opening thus formed.

810,665. MOLD FOR BUTTER. JOSEPH MLADA, Manitowoc, Wis. Filed Oct. 10, 1905. Serial No. 282,122.

Claim.—The combination with a butter-working table having an aperture therein, supports for the table and a cross-strip connecting the supports; of side and end walls depending from the edges of the aperture and constituting the walls of a mold, said mold being subdivided into compartments, a follower slidably mounted within each compartment, a slide, standards extending from the slide and secured to the followers, a guide upon the cross-strip and engaging the slide, a pedal pivoted to the cross-strip and one end of the treadle engaging a standard to simultaneously actuate the slide and standards, a bracket extending laterally from the slide and overlapping the cross-strip, and an adjusting-screw mounted within the bracket and normally contacting with the cross-strip.



810,666. GOVERNOR FOR PUMPING-ENGINES. CHARLES P. MCMULLEN, Brooklyn, N. Y., assignor of one-half to William E. Hye, Wareham, Mass. Filed Oct. 4, 1905. Serial No. 281,281.



Claim.—1. The combination with the cylinder of the governor of a pumping-engine of a trap connected with one end of said cylinder and with the main water-pipe of the pump, and means for supplying oil to the said end of said cylinder and said trap, substantially as shown and described.

2. The combination with the cylinder of the governor of a pumping-engine of a trap connected with one end of said cylinder and with the main water-pipe of the pump, and means for supplying oil to the said end of said cylinder and said trap, and also to the opposite end of said cylinder, substantially as shown and described.

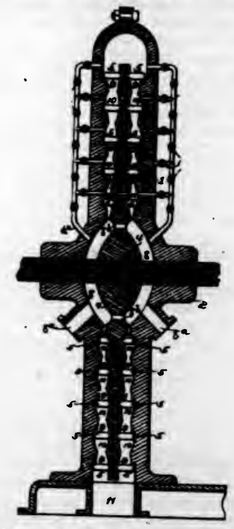
3. In an apparatus of the class described, a cylinder, a trap connected with one end thereof, a piston movable in said cylinder, and means for supplying oil to both ends of said cylinder, substantially as shown and described.

4. In an apparatus of the class described, a vertically-arranged cylinder, a trap connected with the lower end thereof, and means for supplying oil to the upper end of said cylinder, and to the lower end portion thereof which is connected with said trap, substantially as shown and described.

5. In a governor for pumping-engines, a cylinder, a trap connected with one end thereof and also in operative connection with the water-pipe of the pump, and means for supplying oil to said trap, substantially as shown and described.

6. In a governor for pumping-engines, a cylinder, a trap connected with one end thereof and also in operative connection with the water-pipe of the pump, and means for supplying oil to said trap, and also to the opposite end of said cylinder, substantially as shown and described.

810,667. ELASTIC-FLUID TURBINE. PAUL C. OSSANYAN, Newark, N. J., assignor of one-fourth to The Adams Bagnall Electric Company, Cleveland, Ohio, and one-fourth to George A. Thomson, Somerville, N. J. Filed July 10, 1905. Serial No. 269,094.



Claim.—1. In an elastic-fluid turbine, a combination of a rotary element and a series of annular chambers, each chamber being constructed to transform pressure into kinetic energy and discharge it against a single row of buckets upon the rotary element.

2. In an elastic-fluid turbine, the combination of a rotary element, several rows of buckets on said rotating element, and annular chambers formed between the stationary and rotary members on opposite sides of each series of buckets, said chambers being constructed to transform pressure into kinetic energy and compel the buckets to absorb the kinetic energy developed by said chambers.

3. In a turbine, the combination of a rotary element having several rows of buckets, a stationary element, and said elements so constructed as to form annular chambers between them constructed to transform pressure into kinetic energy between each series of buckets.

4. A radial-flow turbine, the combination of a rotary element, several rows of buckets on said rotating element and annular chambers formed between the stationary and rotary members on opposite sides of each series of buckets, said chambers being constructed to transform pressure into kinetic energy and compel the buckets to absorb the kinetic energy developed by said chambers.

5. In a radial-flow turbine, the combination of a rotating element, several series of buckets thereon and a stationary element forming a series of concentric annular chambers for transforming pressure into kinetic energy between said series of buckets, said chambers increasing in area from the axis to the periphery of the rotating element.

6. In an elastic-fluid turbine, the combination of a series of annular chambers designed to transform pressure into kinetic energy, each chamber discharging against a single row of buckets and each chamber having a by-pass for adjusting the pressure therein.

7. In a radial-flow turbine the combination of a series of annu-

lar chambers designed to transform pressure into kinetic energy, each chamber discharging against a single row of buckets, and each chamber having a by-pass for adjusting the pressure therein.

8. In an elastic-fluid turbine the combination of annular chambers formed between the stationary and rotary members for transforming pressure into kinetic energy, discharging into receiving-chambers of approximately the same pressure and buckets to absorb the kinetic energy.

9. In an elastic-fluid turbine the combination of an alternate series of annular chambers formed between the stationary and rotary members constructed to transform pressure into kinetic energy, and receiving-chambers and buckets to absorb the kinetic energy.

10. In a radial-flow turbine the combination of an alternate series of annular chambers formed between the stationary and rotary members constructed to transform pressure into kinetic energy, and receiving-chambers and buckets to absorb the kinetic energy.

11. The combination of an elastic-fluid turbine in which the rotating and stationary elements form chambers constructed to transform pressure into kinetic energy, and receiving-chambers and buckets to absorb the kinetic energy.

12. The combination of a radial-flow turbine in which the rotating and stationary elements form chambers constructed to transform pressure into kinetic energy, and receiving-chambers and buckets to absorb the kinetic energy.

13. In an elastic-fluid turbine the combination of a rotary member with several series of buckets mounted thereon, constructed so that each series of buckets rotates in a chamber formed between the stationary and rotary members and receiving direct impact of the elastic fluid from annular chambers formed between the stationary and rotary members constructed to transform pressure into kinetic energy.

14. In a radial-flow turbine the combination of a rotary member with several series of buckets mounted thereon, constructed so that each series of buckets rotates in a chamber formed between the stationary and rotary members and receiving direct impact of the elastic fluid from chambers formed between the stationary and rotary members constructed to transform pressure into kinetic energy.

15. In an elastic-fluid turbine the combination of a rotary member with several series of buckets constructed so that each series of buckets rotates in a chamber formed between the stationary and rotary members and receiving direct impact of the elastic fluid from an annular chamber formed between the stationary and rotary members constructed to transform pressure into kinetic energy.

16. In a radial-flow turbine the combination of a rotary member with several series of buckets constructed so that each series of buckets rotates in a chamber formed between the stationary and rotary members and receiving direct impact of the elastic fluid from an annular chamber formed between the stationary and rotary members constructed to transform pressure into kinetic energy.

17. In an elastic-fluid turbine, the combination of a rotary element, having buckets and a port or hole for equalizing the pressure on both sides, and a series of annular chambers constructed to adiabatically expand the elastic fluid.

18. In a turbine, the combination of a rotating element having a port or hole for equalizing the pressure on both sides, and a series of buckets on said rotating element, and annular chambers on opposite sides of the buckets constructed to adiabatically expand the elastic fluid and compel the buckets to absorb the kinetic energy developed by said chambers.

19. In a turbine, the combination of a rotating element, having a port or hole for equalizing the pressure on both sides, a stationary element, and said elements so constructed as to form annular chambers to adiabatically expand the elastic fluid.

20. In a radial-flow turbine, the combination of a stationary element, a rotary element having buckets and a port or hole for equalizing the pressure on both sides, and both elements constructed to form between them annular chambers to adiabatically expand the elastic fluid.

21. In a radial-flow turbine, the combination of a casing, and a shaft therein, of a rotary element having a port or hole for equalizing the pressure on both sides, in the casing secured on the shaft, several series of buckets on both sides of the rotary element, and said rotary element and casing so constructed as to form annular chambers at each series of buckets to adiabatically expand the elastic fluid.

22. In a radial-flow turbine, the combination of a rotating element having buckets and a port or hole for equalizing the pressure on both sides, and stationary elements forming a series of annular chambers for the adiabatic expansion of steam, said chambers increasing in area from the axis to the periphery of the rotating element.

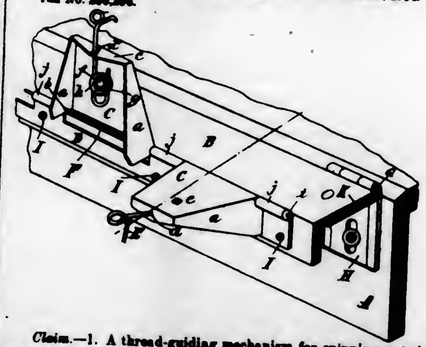
23. In a turbine, the combination of buckets and two independent sets of annular chambers for transforming pressure into kinetic energy, formed between the stationary and rotary members, annular receiving-chambers and means for equalizing pressure between any annular receiving-chamber on one side and the corresponding annular receiving-chamber of the other side.

24. In a radial-flow turbine the combination of a rotary member balanced against pressure by means of a port or hole in said rotary member, each side of said stationary and rotating member forming a series of annular chambers constructed to adiabatically expand the elastic fluid.

25. In a radial-flow turbine, the combination of a balanced rotary member, having a port or hole in said rotary member, vanes or buckets on each side of said rotary member, and a stationary member on each side of said rotary member constructed to form a series of annular chambers for the adiabatic expansion of the elastic fluid.

26. In a radial-flow turbine, the combination of a rotating member having buckets and a port or hole for equalizing the pressure on both sides, and a stationary element forming a series of annular chambers constructed to adiabatically expand the elastic fluid, each chamber having a by-pass by which the pressure therein may be adjusted.

810,668. THREAD-GUIDE MECHANISM FOR SPINNING OR TWISTING MACHINES. OSCAR L. OWEN and JOHN F. SHELLING, Whitinsville, Mass., assignors to The Whitin Machine Works, Whitinsville, Mass., a Corporation of Massachusetts. Filed Dec. 10, 1904. Serial No. 236,206.



Claim.—1. A thread-guiding mechanism for spinning or twisting machines comprising a back rail and thread-guide holders hinged thereto and formed of sheet metal with downturned side flanges, a hinge-wire piercing said flanges, and a downturned back flange covering said hinge-wire and closing the space between the holder and said back rail, substantially as described.

2. In a thread-guiding mechanism for spinning or twisting machines, a sheet-metal holder composed of a flat top with downwardly-turned side flanges forming stops and having apertures in the rearward upper corners thereof, in combination with a hinge-wire passing through said aperture, and a back flange on said holder forming a protective covering for said hinge-wire between the side flanges, substantially as described.

810,669. TENSION DEVICE FOR LOOM-SHUTTLES. PATRIK L. PETERSEN, North Grosvenor Dale, Conn., assignor to Draper Company, Hopedale, Mass., a Corporation of Massachusetts. Filed June 7, 1905. Serial No. 264,041.

Claim.—1. In a loom-shuttle provided with a threading device, a tension member extended rearwardly from and beyond said device and projecting under the path of the thread to a point past and below the tip of the bobbin.

2. In a loom-shuttle having a bobbin-receiving opening and a threading device at one end thereof, a tension member extended rearwardly from and beyond said device and projecting under the path of the thread to a point past the tip of the bobbin, the thread and laterally widened to extend from one to the other side of the bobbin-receiving opening.

3. In a loom-shuttle provided with a threading device, a flexible tension member of textile material extended rearwardly from and beyond said device and laterally widened, and projecting below the path of the thread to a point past the tip of the bobbin.

4. In a loom-shuttle provided with a threading device, a non-metallic, tongue-like tension member extended rearwardly from and beyond said device and projecting under the path of the thread from the bobbin to the threading device.

5. In a loom-shuttle having a bobbin-receiving opening and a threading device at one end thereof, a flexible tension member located in said opening below the path of the thread between the bobbin and the threading device and having a transversely-concave upper face.

6. In a loom-shuttle having a bobbin-receiving opening and a threading device at one end thereof, a tension member of textile material attached to and extended rearwardly from the threading device into said opening and widened to engage the side walls thereof, said tension member projecting under the path of and to act upon the thread between the bobbin and the threading device.

7. In a loom-shuttle having a bobbin-receiving opening and a threading device at one end thereof containing a thread-passage, opposite overhanging shoulders on the side walls of the opening, and a flexible tension member extended rearwardly from and beyond the inner end of the thread-passage under the path of the thread between the bobbin and said passage and having its side edges extended beneath the overhanging shoulders.

8. In a loom-shuttle having a bobbin-receiving opening and an automatically-self-threading device at one end thereof, a flexible tension member extended rearwardly from and beyond said device and projecting under the path of the thread to a point past the tip of the bobbin, to exert tension upon and prevent ballooning and kinking of the thread and yielding to permit the ejection of the bobbin from the shuttle.

9. In a loom-shuttle having an automatically-self-threading device provided with a thread-passage, a tongue-like tension member of textile material extended rearwardly from the inner end of said passage below the path of the thread, the rear end of said member being longitudinally and rearwardly inclined and transversely concaved beneath the tip of the bobbin.

10. In a loom-shuttle having a bobbin-receiving opening and an automatically-self-threading device at one end thereof, a flexible tension member attached to the inner end of said device and extended rearwardly therefrom into said opening under the path of the thread and the tip of the bobbin and widened to prevent the thread from catching between the sides of the opening and the edges of the tension member.

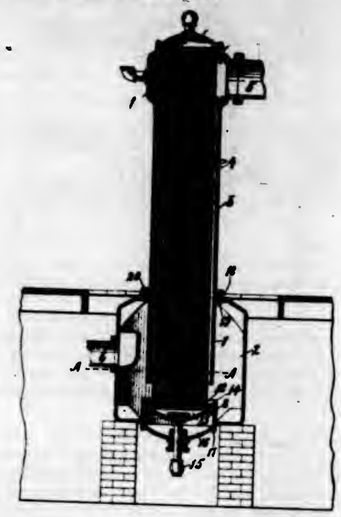
11. In a loom-shuttle having a bobbin-receiving opening provided at one end with overhanging shoulders on its side walls, and a threading device at the shouldered end of the opening, a flexible tension member fixedly secured at its outer end and rearwardly extended from and beyond the threading device under the path of the thread leading from the tip of the bobbin, the free inner end of the tension member being widened and extending beneath the overhanging shoulders.

12. In a loom-shuttle provided with a threading device, a flexible, tongue-like tension member fixedly secured at one end adjacent the threading device, and extended rearwardly therefrom the opposite free end of said member being concaved and projecting under the tip of the bobbin and below the path of the thread passing therefrom to the threading device.

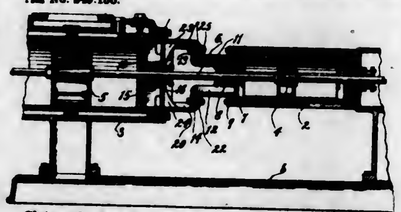
810,670. COOLER FOR COMPRESSORS. WILLIAM PRELLWITZ, Boston, Pa., assignor to The Ingersoll-Sergeant Drill Company, New York, N. Y., a Corporation of West Virginia. Filed Apr. 14, 1903. Serial No. 152,562.

Claim.—1. A cooler for compressors comprising a stack of cooling-tubes, a casing therefor having an upper fluid-inlet head, a lower fluid-discharge head, and a connecting body portion extended into the interior of the fluid-discharge head about the portion of the stack of tubes extended therein and removably secured to the discharge-head whereby the air is confined to the stack of tubes within the discharge-chamber and the cooling-tubes may be removed from the discharge-head by a comparatively short upward movement of the body portion.

2. A cooler for compressors comprising a stack of tubes, a casing therefor having an upper fluid-inlet head, a lower fluid-discharge head, a connecting body portion extended downwardly into the interior of the lower fluid-discharge head about the portion of the stack of tubes extended therein and removably secured to the discharge-head and a tubular guide projecting upwardly into the interior of the fluid-discharge head within which guide the lower end of the stack of tubes is fitted to slide.



810,671. SEPARABLE HEAD-COUPLING. WILLIAM PRELLWITZ, Boston, Pa., assignor to The Ingersoll-Sergeant Drill Company, New York, N. Y., a Corporation of West Virginia. Filed Mar. 8, 1905. Serial No. 249,135.



Claim.—1. A separable head-coupling for alined cylinders comprising two cylinder-heads having shanks removably secured together, one of the heads when released being arranged to permit its shank to telescope within the shank of the other head.

2. A separable head-coupling for alined cylinders comprising two cylinder-heads each having a shank provided with segmental lateral flanges, the flanges of both shanks being removably secured together and arranged to permit the assembling of the heads and the telescoping of one shank within the other when the flanges are released.

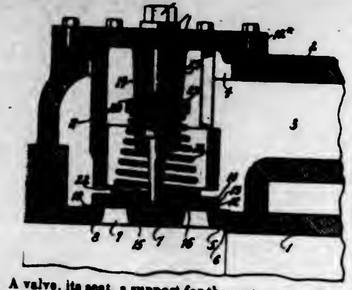
3. A separable head-coupling for alined cylinders comprising two cylinder-heads, one head having a shank provided with inwardly-projected segmental lateral flanges and the other head having a shank provided with outwardly-projected segmental lateral flanges, the flanges of both shanks being removably secured together and arranged to permit the assembling of the heads and the telescoping of one shank within the other when the flanges are released.

810,672. DISCHARGE-VALVE FOR FLUID-COMPRESSORS. WILLIAM PRELLWITZ, Boston, Pa., assignor to The Ingersoll-Sergeant Drill Company, New York, N. Y., a Corporation of West Virginia. Filed Apr. 1, 1903. Serial No. 151,947.

Claim.—1. A valve-seat, a valve, its spring for yieldingly holding the valve closed, a removable valve-guide engaged with the seat and means for yieldingly holding the valve guide and seat in position.

2. A laminated valve, its seat, a support for the seat, a centrally-arranged removable guide for the valve, means for yieldingly

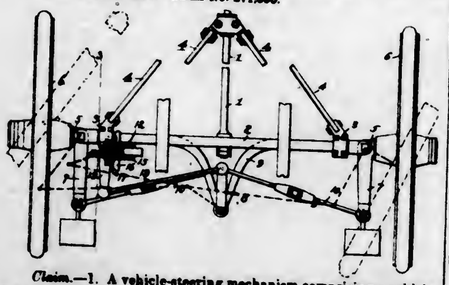
holding the valve closed and means for yieldingly holding the valve guide and seat in position.



3. A valve, its seat, a support for the seat, a centrally-arranged removable valve-guide locked to the seat against lateral movement, means for yieldingly holding the valve closed and means for yieldingly holding the valve-seat and valve-guide in position.

4. A valve, its seat, a support for the seat, a centrally-arranged removable valve-guide comprising a plate countersunk into the valve-seat and guide-fingers uprising therefrom, a spring for yieldingly holding the valve closed and means for yieldingly holding the valve guide and seat in position.

810,673. VEHICLE-STEERING MECHANISM. FRANK B. RAE, Chicago, Ill., assignor to The American Electromobile Company, East Orange, N. J., a Corporation of New Jersey. Filed June 4, 1898. Renewed July 26, 1905. Serial No. 271,260.

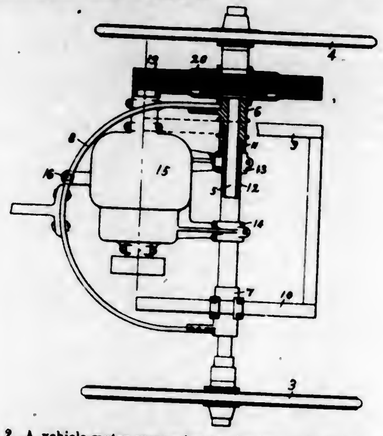


Claim.—1. A vehicle-steering mechanism comprising a vehicle-frame reach-rod, an axle mounted at its center upon said rod and having its ends free to move vertically but not horizontally, brace-rods connecting the ends of the axle with said reach-rod, a pair of wheel-shafts pivotally attached to the axle near the ends thereof, a pair of wheels mounted upon said wheel-shafts, wheel-levers integrally connected with said wheel-shafts, a differentiating lever having pivotal connection with said axle, connections between the outer ends of said wheel-levers and of said differentiating lever, a hand-lever mounted for movement in a vertical plane, an auxiliary lever mounted upon a vertical pivot, connections between said hand-lever and said auxiliary lever, and a floating rod connecting said auxiliary lever and said differentiating lever.

2. A vehicle-steering mechanism comprising a vehicle-frame reach-rod, an axle mounted at its center upon said rod and having its ends free to move vertically but not horizontally, brace-rods connecting the ends of the axle with said reach-rod, a pair of wheel-shafts pivotally attached to the axle near the ends thereof, a pair of wheels mounted upon said wheel-shafts, wheel-levers integrally connected with said wheel-shafts, a differentiating lever having pivotal connection with said axle, connections between the outer ends of said wheel-levers and of said differentiating lever, a hand-lever mounted for movement in a vertical plane, an auxiliary lever mounted upon a vertical pivot, gears forming connections between said hand-lever and said auxiliary lever, and a floating rod having ball-and-socket connection with said auxiliary lever and said differentiating lever.

810,674. VEHICLE-MOTOR-SUSPENSION MECHANISM. FRANK B. RAE, Detroit, Mich., assignor to The American Electromobile Company, East Orange, N. J., a Corporation of New Jersey. Filed Sept. 7, 1905. Serial No. 277,470.

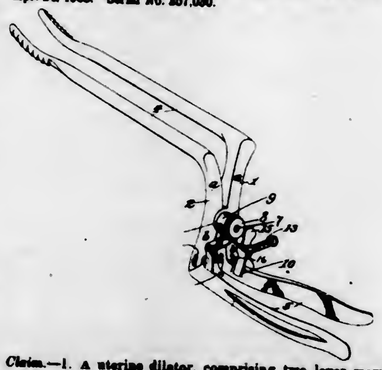
Claim.—1. A vehicle-motor-suspension mechanism comprising a driving-axle, a plurality of vehicle-supporting journal-boxes thereon, a tube connecting two adjacent boxes and inclosing said axle, and a motor having its axle end rotatably mounted upon said tube and its free end yieldingly supported from some other portion of the vehicle, substantially as described



2. A vehicle-motor-suspension mechanism comprising a driving-axle, a plurality of vehicle-supporting journal-boxes thereon, a tube connecting two adjacent boxes and inclosing said axle, and a motor having its axle rotatably mounted upon said tube and having its free end engaged between yielding supports upon both sides thereof and connected with some other portion of the vehicle, whereby strain upon the motor in moving either forward or backward is reduced to a minimum.

3. A vehicle-motor-suspension mechanism comprising a driving-axle, a plurality of vehicle-supporting journal-boxes, a vehicle-frame supported on said boxes, a connection between two adjacent boxes, and a motor having its axle end rotatably supported upon said connection and its free or outer end yieldingly supported from said frame, substantially as described.

810,675. DILATOR. GUSTAV F. RICHTER, New York, N. Y. Filed Apr. 24, 1905. Serial No. 257,090.



Claim.—1. A uterine dilator, comprising two lever members each provided with a blade and a handle respectively disposed at an angle thereto and substantially parallel with each other, in combination with a fulcrum-joint between said members having its pivotal axis substantially parallel with said handles and comprised of a tubular extension on one lever member and a pin on the other received thereby.

2. A dilator comprising two opposed lever members each provided with a blade and a handle, a fulcrum-joint between said lever members and an extension on one of them, in combination with a spring on said extension having its free ends bearing against said handles.

3. A uterine dilator, comprising two opposed lever members each provided with a blade and a handle respectively disposed at an angle thereto and substantially parallel with each other, a fulcrum-joint between said lever members having its axis substantially parallel with said blades and handles and comprising a tubular extension on one lever member and a pin on the other received thereby, in combination with a spring embracing said tubular extension adapted to exert an opening tendency upon the handle ends of said lever members.

4. A uterine dilator, comprising two lever members each provided with a blade and a handle respectively disposed at an angle thereto and substantially parallel with each other, a fulcrum-joint between said members having its axis substantially parallel with said blades and handles and comprising a tubular extension on one of said members and a pin on the other received thereby, in combination with means for retaining said pin therein and a spring confined on said extension by said means and arranged to exert an opening tendency upon the handle ends of said lever members.

5. A dilator, comprising two opposed lever members each provided with a blade and a handle, a tubular extension provided on one member and a pin on the other received by said extension to afford a fulcrum-joint for said members, in combination with a bow-spring embracing said extension, and seats provided in the region of the juncture of said handles and lever members for retaining the free ends of said spring.

6. A dilator, comprising two opposed lever members each provided with a blade and a handle substantially parallel to each other, a tubular extension provided on one member and a pin on the other received thereby, in combination with a bow-spring embracing said extension and contracted below the same to prevent the accidental removal of said spring therefrom.

7. A dilator comprising two lever members each provided with a blade and a handle, a screw for forcing relative movement thereof, means for securing one end of said screw to one member and a spring acting upon said members and retaining said means in operative position.

8. In a dilator, two lever members each formed with a blade and a handle, a screw for forcing relative movement thereof located in slots therein, a cross-aperture intersecting one of said slots and a pin in said aperture having holding engagement with said screw, in combination with an extended fulcrum-joint between said members, a spring confined thereon and serving to confine said pin in its aperture.

9. In a dilator, two lever members, a tubular barrel forming a part of one member and a pin forming a part of the other and received in said barrel, a blade and a handle respectively provided for each member and disposed substantially parallel with the pivotal axis formed by said pin and barrel.

10. In a dilator, two lever members comprised respectively of a blade-section, barrel and handle section, and a blade-section, pin and handle section, said pin and barrel constituting a fulcrum-joint for said members and blades and handles respectively for said members disposed substantially parallel with the pivotal axis of said joint.

11. In a surgical instrument, a pair of lever members respectively having handles extending at an angle thereto and a transverse fulcrum-joint for said members provided with an axial extension, in combination with a spring confined on said extension with its free ends bearing respectively against said handles.

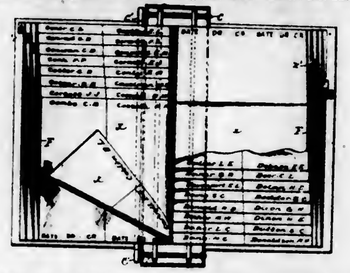
810,676. POISON-BOTTLE STOPPER. LOUIS H. RITTER, Estherville, Iowa. Filed Apr. 4, 1905. Serial No. 253,794.

Claim.—1. A stopper for poison-bottles having a guard placed diametrically across the stopper and projecting beyond the opposite sides of the stopper, and spurs struck downwardly from the guard and engaging opposite sides of the stopper.

2. The combination with a stopper of a guard having a flat body portion and longitudinally split adjacent each end, one of said split members at each end being pointed at its extreme end and adapted to extend outwardly beyond the stopper and in the plane of the body portion of the guard, and the other member being bent downwardly and inwardly forming a spur adapted to engage the sides of the cork, the said spurs being offset with respect to each other

---

810,677. LEDGER. FRANK J. ROSENBERG and CHARLES B. ROSENBERG, Los Angeles, Cal. Filed Aug. 23, 1904. Serial No. 221,839.



Claim.—1. A ledger consisting of suitable clamping means and transverse wires *a* for the leaves, a plurality of sets of leaves provided with tabs *b* and stepped and indexed on both sides, spacer-sheets for the several sets of leaves, and wedge-shape pads F at both ends of said spacer-sheets, substantially as described.

2. A ledger consisting of a plurality of sets of leaves stepped and indexed on both sides, and provided with tabs *b*, on one edge, spacer-sheets, and wedge-shape pads F alongside of said spacer-sheets, and a suitable binder for the leaves, whereby the stepping is accurately effected, substantially as described.

810,678. GARMENT-CLASP. SELVYN RUBIN, New York, N. Y. Filed May 2, 1905. Serial No. 258,519.

Claim.—1. In a garment-clasp, the combination with a base-plate, having an upwardly-extending projection on its upper surface, of a clamping-plate pivoted to the base-plate and having a part punched out to form a spring-tongue, and a recess above said spring-tongue, a pivoted locking-lever adapted to fold into the said recess in the clamping-plate, the free end of the spring being adapted to slide on the said projection, substantially as set forth.

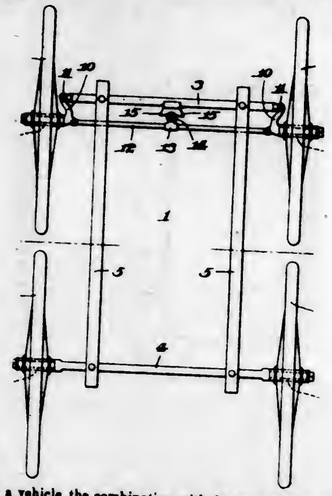
2. In a garment-clasp, the combination with a base-plate having flat pivot projections at its sides and extending over the upper surface of the base-plate, of a clamping-plate having side flanges provided with substantially triangular openings widest at their front ends, into which said flat pivots on the base-plate project and a locking-plate for the clamping-plate, substantially as set forth.

3. In a clasp, the combination with a base-plate having flanges and a lip made integral with one of said flanges and extending over the upper surface of said base-plate, a rubber covering on said lip, a clamping-plate pivoted to the base-plate and provided with downwardly-extending flanges at its free end, which flanges, when the clamping-plate is closed, surround the rubber covering of said lip, substantially as set forth.

810,679. STEERING DEVICE FOR VEHICLES. GEORGE K. RUDDY, Wilmington, Del. Filed Mar. 7, 1905. Serial No. 248,839.

Claim.—1. In a vehicle, the combination with the body portion thereof, of a pair of oppositely-disposed spindles each being pivotally connected to the body portion forwardly of a line passing through the axes of the spindles, supporting-wheels on the spindles, said spindles being adapted to be adjusted on their pivots to vary the angularity of the wheels to steer the vehicle, and means for automatically returning said spindles into alinement after the steering operation.

2. In a vehicle, the combination with the body portion thereof, of a pair of oppositely-disposed spindles each being pivotally connected to the body portion forwardly of a line passing through the axes of the spindles, supporting-wheels on the spindles, connections between said spindles whereby they may be adjusted in unison to vary the angularity of the wheels to steer the vehicle, and means for automatically returning said spindles into alinement after the steering operation.



3. In a vehicle, the combination with the body portion thereof, of a pair of oppositely-disposed spindles each being pivotally connected to the body portion forwardly of a line passing through the axes of the spindles, supporting-wheels on the spindles, a rod pivotally connected at its ends to the spindles whereby they may be adjusted in unison to vary the angularity of the wheels to steer the vehicle, and means for yieldingly maintaining said spindles in alinement.

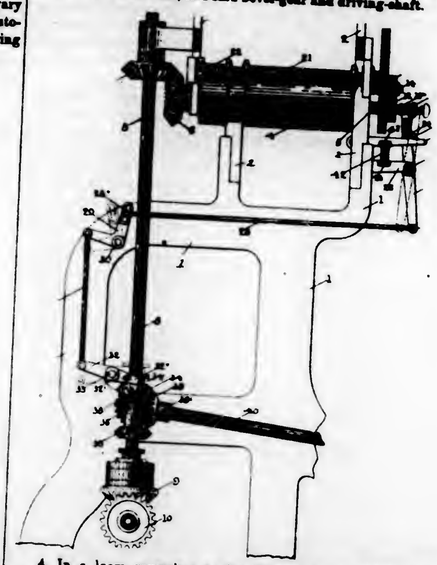
4. In a vehicle, the combination with the body portion thereof, of a pair of oppositely-disposed spindles each being pivotally connected to the body portion forwardly of a line passing through the axes of the spindles, supporting-wheels on the spindles, a spring-rod pivotally connected at its ends to the spindles whereby they may be adjusted in unison to vary the angularity of the wheels to steer the vehicle a pair of oppositely-disposed cams, and means on the rod for engaging the cams whereby said cams will cause the rod to automatically return the spindles into alinement after the steering operation.

810,680. LOOM REVERSING MECHANISM. IEPPA H. RYON, Worcester, Mass., assignor to Crompton & Knowles Loom Works, a Corporation of Massachusetts. Filed Apr. 24, 1905. Serial No. 257,057.

Claim.—1. In a loom take-up reversing mechanism, a sliding key for reversing through a system of gears the pattern-cylinder shaft, and said gears and said cylinder-shaft, and the driving-shaft of the take-up mechanism, and connections intermediate said sliding key and said driving-shaft.

2. In a loom take-up reversing mechanism, a sliding key for reversing through a system of gears the pattern-cylinder shaft, and said gears and pattern-cylinder shaft, and the driving-shaft of the take-up mechanism, and connections intermediate said sliding key and said driving-shaft, said connections comprising a pivoted lever, and connections intermediate said lever and a sleeve on a shaft, and said sleeve revolving with and movable on said shaft and having two bevel-gears thereon, either one adapted to be moved into engagement with a third bevel-gear, and said third bevel-gear in engagement with the bevel-gear fast on the driving-shaft of the take-up mechanism, and said bevel-gear.

3. In a loom take-up reversing mechanism, a sliding key for reversing through a system of gears the pattern-cylinder shaft, and said gears and pattern-cylinder shaft, and the driving-shaft of the take-up mechanism, and connection intermediate said sliding key and said driving-shaft, said connections comprising a pivoted lever, and a locking-lever, and connections intermediate said pivoted lever and a sleeve on a shaft, and said sleeve revolving with and movable on said shaft, and having two bevel-gears thereon, either one adapted to be moved into engagement with a third bevel-gear, and said third bevel-gear in engagement with the bevel-gear fast on the driving-shaft of the take-up mechanism, and said bevel-gear and driving-shaft.

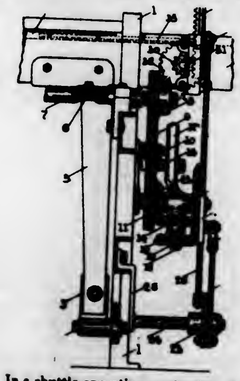


4. In a loom reversing mechanism for the pattern-cylinder shaft, a shaft for a take-up, gears for driving said take-up shaft, either in a forward or backward direction, and connections between said gears and said reversing mechanism.

5. In a loom reversing mechanism for the pattern-cylinder shaft, the combination with a sliding key for reversing, through a system of gears, the pattern-cylinder shaft, of a pivoted lever, engaging said key in its inner and outer position and acting to support said key, and hold it in its proper position.

6. In a loom reversing mechanism for the pattern-cylinder shaft, the combination with a sliding key for reversing, through a system of gears, the pattern-cylinder shaft, of a pivoted lever engaging said key in its inner and outer position, and acting to support said key, and hold it in its proper position, and a second lever for locking or holding said pivoted lever.

810,681. SHUTTLE-OPERATING MECHANISM. IEPPA H. RYON, Worcester, Mass., assignor to Crompton & Knowles Loom Works, a Corporation of Massachusetts. Filed Apr. 24, 1905. Serial No. 257,068.



Claim.—1. In a shuttle-operating mechanism of a narrow-ware loom, a shuttle-rack, a gear having a crank-pin thereon, means to rotate said gear to cause it to dwell at the end of each half-rotation thereof, and rigid connections intermediate said crank-pin and said shuttle-rack, said connections comprising a connector to a central pivoted lever, and said lever, and a connector therefrom to a vertically-moving rack, and said rack, and gears intermediate said rack and the shuttle-rack, substantially as described.

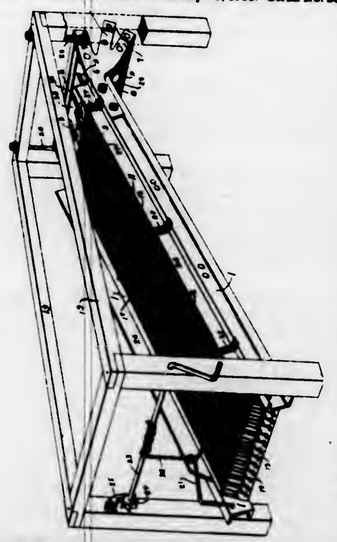
2. In a shuttle-operating mechanism of a narrow-ware loom, a shuttle-rack, a gear having a crank-pin thereon, means to rotate said gear to cause it to dwell at the end of each half-rotation thereof, and rigid connections intermediate said crank-pin and said shuttle-rack, substantially as described.

3. In a loom of the class described, a crank-gear, an oscillating arm having thereon a hub, and two bevel-gears connected with said hub, one of said gears meshing with said crank-gear, and the other meshing with and driven by a gear, and said gear, and means to cause said hub to oscillate, substantially as described.

4. In a loom of the class described, a shuttle-rack, rigid connections to a crank-gear, and said crank-gear, an oscillating arm having thereon a hub, and two bevel-gears connected therewith, one of said gears meshing with said crank-gear, and the other meshing with and driven by a gear, and said gear, and means to cause said hub to oscillate, substantially as described.

5. In a shuttle-operating mechanism, the combination with a gear, a crank, an eccentric pivotal support for said crank, and connections intermediate said crank and gear, of connections intermediate said crank and the swivel-shuttle rack for operating the swivel-shuttles, substantially as described.

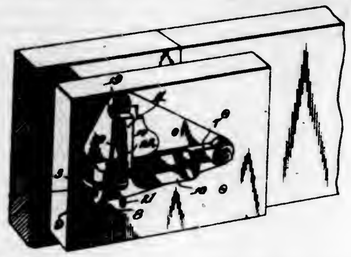
810,682. SAND OR CLAY SCREEN. LEMUEL P. SHAFER and CHARLES DEVIN, Canton, Ohio. Filed Apr. 3, 1905. Serial No. 253,611.



Claim.—1. In a screen of the class described, the combination of a suitable frame, consisting of side members and tie-bars, heads carried by the frame said heads provided with tension-bars and the tension-bars located in different horizontal planes, wire-holding bars secured to said tension-bars and independently adjustable, a series of screen-wires secured to the independently-adjustable holding-bars at one of their ends and their opposite ends secured in fixed position and means for holding the screen-wires in spaced relation to each other, substantially as and for the purpose specified.

2. In a screen of the class described, the combination of a suitable frame, the side members of said frame consisting of channel-bars, means for holding the side members in proper spaced relation, a tension-head provided with tension-bars, said tension-bars located in different horizontal planes, a series of screen-wires held in fixed relation with reference to the frame at one of its ends, said screen-wires secured to independent adjustable wire-holding bars at their opposite ends, said adjustable wire-holding bars located in series and in different planes, and a bridge-bar located intermediate the ends of the screen-wires, and means for adjusting the bridge-bar to and from the screen-wires, substantially as and for the purpose specified.

810,683. LATCH FOR WAGON END-GATES. CHARLES W STARK, Mountain Lake, Minn. Filed Apr. 17, 1905. Serial No. 255,990.



Claim.—1. In a lock the combination with a base-plate; of an arm pivoted at one end thereto, a handle upon the arm, a bolt extending from one end of the arm at an angle thereto and adapted to engage a keeper, a guide-strip extending over the arm and adapted to limit its movement in both directions, and means engaging the arm for locking the bolt against movement.

2. In an end-gate, the combination with hinged members, a keeper extending from one of said members, an apertured strip secured to the other member and adapted to receive the keeper; of a latch secured to said strip and comprising a base-plate, an arm pivoted thereto, a bolt extending at an angle from the arm and adapted to engage the keeper, a guide secured to the base and extending over the arm, and means engaging the arm for locking the bolt against withdrawal from its keeper.

3. A latch comprising a base-plate, an arm pivoted thereto, a bolt extending from the arm at an angle thereto and adapted to engage a keeper, a guide for the bolt, a spring-pressed locking-plate pivoted to the base and normally overlapping the arm, and a spring-arm secured to the base and normally engaging the pivoted arm.

4. In a latch, the combination with a depressible locking-plate; of a swinging arm adapted to slide upon the plate, means for automatically moving the plate into the path of the arm and to lock the same after sliding thereon, and a bolt extending from the arm.

5. In a latch, the combination with a recessed support; of a spring-pressed locking device within the recess, a swinging arm mounted upon the support and adapted to slide upon and to be automatically engaged by the locking device, and a bolt extending from the arm.

6. In a latch, the combination with a spring-controlled bolt-locking device; of a swinging arm adapted to slide over said device, and to be automatically held thereby, and a bolt extending from the arm.

7. In a latch, the combination with a base having a swinging arm connected thereto and a bolt extending from the arm; of a spring-pressed locking device pivoted to the base and normally in the path of the arm, and a spring-arm secured to the base and normally engaging the arm.

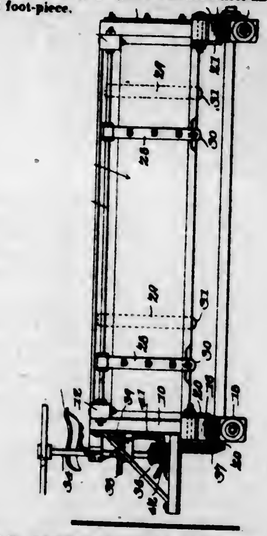
8. In a latch, the combination with a base-plate having an aperture therein, of a swinging arm pivoted to the base and having a handle and a bolt thereon, a guide secured to the base-plate and extending over the arm, and a spring-pressed locking device mounted within and normally projected from the aperture and into the path of the arm.

810,684. DUMPING-WAGON. GREEN R. STARNES, Charlotte, N. C. Filed Feb. 10, 1905. Serial No. 245,134.

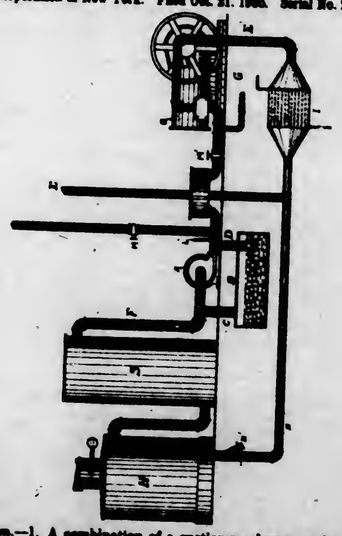
Claim.—1. In a device of the class described, end members removably supported upon the axle-bolsters of a vehicle running-gear and connected by a central conical section, spaced tie-rods extending between said end members, a shaft mounted for rotation in said end members and extending beneath said conical portion, spaced strap members pivotally connected to said tie-rods and provided with chains leading from opposite sides around said shaft, side members connected to said strap members for closing against said conical portion, and means for rotating said shaft and locking the same in any required position.

2. In a device of the class described, end members removably supported upon the axle-bolsters of a vehicle running-gear and con-

nected by a central conical section, a driver's seat carried by the forward end member, spaced tie-rods extending between said end members, side members mounted to swing from said tie-rods for closing against said conical portion, a shaft mounted for rotation in said end members and extending beneath said conical portion, and provided with a bevel-gear, chains for coupling said shaft and side members, a shaft mounted for rotation upon said forward end member and having a hand-wheel upon one end and a bevel-pinion upon the other end for engaging said bevel-gear, a ratchet-wheel upon said vertical shaft, and a pawl engaging said ratchet-wheel and provided with a terminal foot-piece.



810,685. POWER GAS APPARATUS. GODFREY M. S. TAIT, Montclair, N. J., assignor to Combustion Utilities Company, New York, N. Y., a Corporation of New York. Filed Oct. 21, 1905. Serial No. 283,839.



Claim.—1. A combination of a suction-producer; an internal-explosion engine; a connecting-conduit; interposed in said conduit a fan-blower having a liquid-seal by-pass, whereby gas may be delivered under a constant predetermined pressure to the engine, substantially as described.

2. A combination with a suction-producer; a scrubber; a gas-purifier; and gas-engine; a connecting-conduit, of a fan-blower interposed between the gas-producer and the engine having a water seal by-pass whereby gas is withdrawn from the producer and is supplied to the engine under predetermined pressure.

3. Power gas apparatus which comprises a gas-producer; an internal-explosion engine; a connecting-conduit; a mechanical draft appliance interposed in said conduit and a water-seal by-pass around said mechanical draft appliance whereby producer-gas is delivered to the engine under constant predetermined pressure.

810,686. AUTOMATIC OILER. ALBERT H. TAYLOR, Easton, Pa., assignor to The Ingersoll-Sergeant Drill Company, New York, N. Y., a Corporation of West Virginia. Filed July 14, 1905. Serial No. 269,626.

Claim.—1. An automatic oiler for the air-feed pipe of a pneumatic motor comprising an oil-reservoir and a valve controlled by pressure within the pipe for opening and closing communication from the reservoir to the feed-pipe.

2. An automatic oiler for the air-feed pipe of a pneumatic motor comprising an oil-reservoir, a valve controlled by pressure from within the pipe for opening and closing communication from the reservoir to the feed-pipe and means for adjusting the opening movement of the said valve.

3. An automatic oiler for the air-feed pipe of a pneumatic motor comprising an oil-reservoir adjustably mounted on the pipe in a rotary direction and means controlled by pressure from within the pipe for opening and closing communication from the reservoir to the pipe.

4. An automatic oiler for the air-feed pipe of a pneumatic motor comprising an oil-reservoir adjustably mounted on the pipe in a rotary direction, an annular chamber surrounding the pipe, ports in the pipe communicating with the said chamber and a valve controlled by pressure within the pipe for opening and closing communication from the interior of the reservoir to the said annular chamber.

5. An automatic oiler for the air-feed pipe of a pneumatic motor comprising a reservoir, a tubular valve-bushing therein having holes therethrough at different distances from the feed-pipe and a valve fitted to slide in the valve-bushing toward and away from the feed-pipe, the movement of the said valve being controlled by pressure within the feed-pipe for opening and closing communication from the interior of the reservoir to the interior of the feed-pipe.

6. An automatic oiler for the air-feed pipe of a pneumatic motor comprising an oil-reservoir, a valve and a spring for holding the valve closed, the said valve being adapted to be opened by pressure from within the feed-pipe for opening communication from the interior of the oil-reservoir to the interior of the feed-pipe.

810,687. SYSTEM OF AUTOMATIC SIGNALING FOR ELECTRIC RAILWAYS. FRANCIS TOWNSEND, New York, N. Y., assignor to General Railway Signal Company, a Corporation of New York. Filed Nov. 10, 1905. Serial No. 286,741.

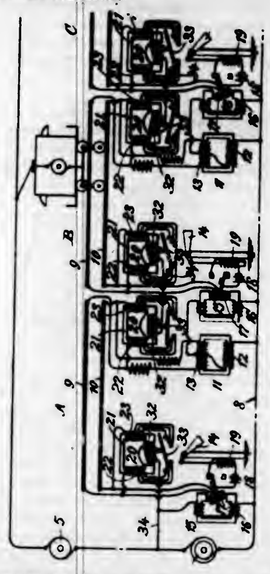
Claim.—1. The combination with a signaling system of the type described provided with cross-bonds for the return conductors or rails, of means whereby the power-current will be equalized in the return-conductors to the source of power-current.

2. The combination with a signaling system of the type described, of automatic means whereby the power-current will be equalized in the return-conductors to the source of power-current.

3. The combination with a signaling system of the type described, of means for automatically varying the resistance of the return-paths for the power-current in inverse proportion and in accordance with the power-current in said paths.

4. The combination with a signaling system of the type described, of means for automatically altering the relative resistance of the return-paths for the power-current, and in proportion to the power-current in said paths.

5. The combination with a signaling system of the type described provided with cross-bonds for the return conductors or rails, of means whereby the power-current will be equalized between the traffic-rails as return-conductors.



6. The combination with a signaling system of the type described, of means for automatically equalizing the power-current between the traffic-rails as return-conductors.

7. The combination with a signaling system of the type described, of reactance bonds, and means for altering the relative resistance of the paths for the power-current through said bonds.

8. The combination with a signaling system of the type described, of reactance bonds, and means for automatically altering the relative resistance of the paths for the power-current through said bonds.

9. The combination with a signaling system of the type described, of reactance bonds including in their structure means for automatically altering the relative resistance of the paths for the power-current through said bonds.

10. The combination with a signaling system of the type described, of reactance bonds having a fixed member with a coil in each path for the return power-current and a movable member adapted to vary the relative resistance of such paths.

11. The combination with a signaling system of the type described, of reactance bonds having a fixed member in the path of the power-current, and a movable member adapted to vary the length of the coil of the member in the path of the power-current.

12. The combination with a signaling system of the type described, of means energized by the power for varying the relative resistance of the return-paths for the power-current and in accordance with the power-current flowing in said paths.

13. The combination with a signaling system of the type described, of a reactance-bond-equalizing device comprising a core having coils thereon in the path of the power-current and wound in opposite directions so as not to magnetize the core, an armature energized by the power-current, and means controlled by the armature whereby the relative resistance of the paths for the power-current through said bond may be varied, and without affecting the reactance of the bond to an alternating current.

14. The combination with a signaling system of the type described, of an inductance bond comprising a core having coils thereon in the path of the power-current, and wound in opposite directions, so as not to magnetize said core, an armature energized by the power-current, and means controlled by the armature whereby the magnetomotive forces of the power-currents in said bond may be varied, and without affecting the reactance of the bond to an alternating current.

15. The combination with a signaling system of the type described, of means energized by the power-current for varying the relative power-current magnetomotive forces, in accordance with the inequality of the power-currents flowing in the traffic-rails.

16. An automatic system of block-signaling, embodying means whereby the return propulsion-currents are automatically equalized between the traffic-rails.

17. An automatic system of block-signaling, embodying means for automatically segregating the alternating signaling-current between the respective blocks of the trackway and for equalizing the power-current between the rails of the railway as return-conductors.

18. An automatic system of block-signaling, embodying means whereby the magnetomotive forces of the power-currents in the inductance bonds are automatically equalized.

19. A signaling system of the type described, comprising traffic-rails of variable relative resistance, inductance bonds wound with wire, adapted to transmit the power-current, and automatic means of magnetomotive-force control, combined with said reactance bonds.

20. A system of block-signaling of the type described, comprising traffic-rails of variable relative resistance, inductance bonds connected to said rails, and a power-current of zero-resultant magnetomotive force, transmitted through said bonds.

21. In a system of automatic signaling of the type described, traffic-rails of varying relative resistance, inductance bonds adapted to transmit the power-current, automatic means energized by the power-current, adapted to reduce the resultant magnetomotive force of the power-current in the body to zero.

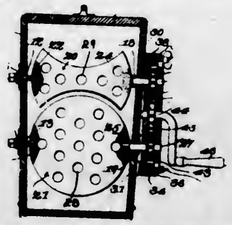
22. In a system of automatic signaling for railways, traffic-rails carrying varying power-currents and means of automatic magneto-force control as to the power-current actuated by the difference in the currents carried by said rails.

23. In a system of automatic signaling, the combination of traffic-rails carrying the power-current, a block-segregating means, transmitting said power-current, and comprising a fixed member, and a movable member actuated by the difference in the currents carried by the traffic-rails, and means of magnetomotive-force control of the power-current combined with said segregating means.

24. In a system of automatic signaling, a block-segregating device comprising an iron core, an automatic means for maintaining zero-unidirectional magnetization in said core and a magneto-force-regulating device combined with it, actuated by the power-current.

25. In a system of automatic signaling, the combination with the traffic-rails of reactance bonds, and means whereby the magnetizing effect of the power-current, separately transmitted over said rails as a return and through the bond, will be equalized within the bond and thereby produce no magnetization of the bond, thus presenting return-paths for the power-current to the source of energy.

810,688. CHURN. EDWARD W. TURNER, Swansboro, Va., assignor of one-half to George M. Rogers, Richmond, Va. Filed July 28, 1905. Serial No. 271,672.



Claim.—In a churn, a receptacle having spaced bearings through one of its side walls, a base-plate attached to said receptacle and with outwardly-extending flanges at the ends and having bearings opposite the bearings in said receptacle and also with an intermediate bearing, a supporting-plate seated at the ends upon the flanges of said base-plate and provided with bearings in alinement with the bearings in said base-plate, dasher members having sockets in one end and disposed within said receptacle, shafts journaled in the bearings in said receptacle and in the bearings in said plates and engaging the sockets in said dasher members a shaft journaled in the intermediate bearings in said plates and provided with an operating-crank intermeshing gear-wheels upon said shafts and means for detachably coupling said supporting-plate to said base-plate.

810,689. INFANT'S DIAPER. WILLIAM R. WAY, Columbia, S. C. Filed June 29, 1905. Serial No. 267,499.

Claim.—1. An infant's diaper comprising a combined excrement and urine receiver, and a urine-deflector communicating therewith.

2. An infant's diaper comprising a combined excrement and urine receiver having a neck, a urine-deflector having a neck, and a conduit having the ends thereof extending into the said necks.

3. An infant's diaper comprising a combined excrement and urine receiver, a urine-deflector communicating therewith, and a shield connected to said receiver.

4. An infant's diaper comprising a combined excrement and urine receiver having a neck, a urine-deflector having a neck, a conduit having the ends thereof extending into the said necks, and a shield connected with said receiver.

5. An infant's diaper comprising a combined excrement and urine receiver, a urine-deflector communicating therewith, attaching-straps connected with the deflector, and attaching-straps connected with the receiver.

6. An infant's diaper comprising a combined excrement and urine receiver, and a urine-deflector communicating therewith and provided with a pocket.

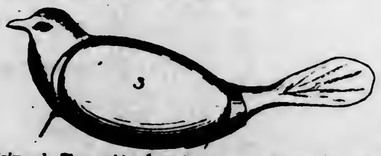
7. An infant's diaper comprising a combined excrement and urine receiver having a neck, a urine-deflector having a neck, and a conduit having the ends thereof extending into the said necks and provided with a valve at one end.

8. An infant's diaper comprising a combined excrement and urine receiver having a top portion provided with a neck adapted to be inverted to permit of the discharge of the contents of said receiver, and a urine-deflector communicating therewith.

9. An infant's diaper comprising a combined excrement and urine receiver, having a top portion provided with a neck adapted to be inverted to permit of the discharge of the contents of said receiver, a urine-deflector, and a conduit for establishing communication between said receiver and deflector.

10. An infant's diaper comprising a combined excrement and urine receiver, having a top portion provided with a neck adapted to be inverted to permit of the discharge of the contents of said receiver, a urine-deflector, a conduit for establishing communication between said receiver and deflector, and a valve in said conduit.

810,690. BIRD-KITE. PROSPER WEISS, Highland Falls, N. Y. Filed Apr. 11, 1905. Serial No. 255,086.



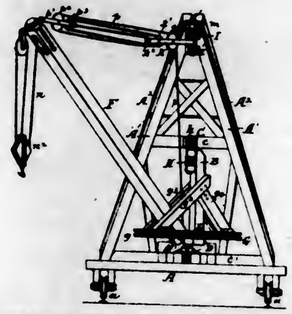
Claim.—1. The combination with an inflatable body; of a covering inclosing the same and comprising a hollow casing simulating a winged creature, said casing having an opening adapted to receive the inflatable body, a closure for said opening adapted to conceal and protect the inflatable body, and a manipulating-cord permanently connected to the casing.

2. A covering for inflatable bodies comprising a hollow casing simulating a winged creature, said casing having an opening adjacent one end adapted to receive an inflatable body, a closure for said opening, and a manipulating-cord secured to said casing.

3. A covering for inflatable bodies comprising a hollow casing simulating a living creature and having an opening adapted to receive an inflatable body, flexible wings extending from the casing, a closure for the opening, and a manipulating-cord secured to and extending from the casing.

810,691. DERRICK. JESSE S. ALLEN, Jr., Philadelphia, Pa. Filed Mar. 24, 1905. Serial No. 251,841.

Claim.—1. The combination of a base-frame, an A-frame and struts supporting said A-frame, a step, a relatively short mast supported in the plane of the A-frame, a foot-block carrying the mast and mounted in the step, a pivot by which the upper end of the mast is secured to the A-frame, a bull-wheel carried by the mast, braces extending from the bull-wheel to the mast, and a boom pivoted to the foot-block and mounted between the braces, substantially as described.



2. The combination in a derrick, of a base-frame, an A-frame carried thereby, a step, a short mast, a foot-block having its pivot mounted in the step and secured to the mast, a boom pivoted to the foot-block, a bull-wheel secured to the foot-block for turning the mast, a socket secured to the upper end of the mast, a pin in the socket and projecting above the mast, a bearing secured to the A-frame into which the pin projects, the pin being in line with the pivot of the foot-block and the mast being out of line, substantially as described.

3. The combination in a derrick, of a base-frame, an A-frame carried thereby, strut-legs extending from the upper portion of the A-frame to the rear of the main frame, a socket at the upper end of the A-frame, a pin mounted in the socket and projecting above the end of the A-frame, gooseneck carried by each strut-leg and having an opening for the passage of the pin, a cross-bar on the A-frame, a short mast mounted between the cross-bar and the base of the frame, a step-bearing for the lower portion of the mast, a pivot for the upper portion of the mast, and a boom, substantially as described.

4. The combination in a derrick, of a base-frame, an A-frame, strut-legs extending from the upper portion of the A-frame to the rear of the base-frame, a step-bearing mounted between the legs of the A-frame, a foot-block having a pivot mounted in the step-bearing, the step-bearing and the foot-block having an open center for the passage of the hoisting-ropes, a boom carried by the foot-block, the step-bearing having an internal upwardly-projecting flange forming an annular cavity for the reception of the pivot and for the accumulation of a lubricant so that the step-bearing will be lubricated at all times, substantially as described.

5. The combination in a derrick, of a mast pivoted at the upper end to the frame and having a foot-block at its lower end, a hollow pivot projecting from the under side of the foot-block, a step-bearing having an open center and having an annular internal flange forming an annular cavity into which the pivot of the foot-block extends, said pivot having a shoulder near its upper end, and a cap secured to the foot-block and extending over the shoulder of the pivot, forming a dust-guard for the bearing, substantially as described.

6. The combination in a derrick, of a pivot, a mast, a boom hung from the mast, a step-bearing for the lower end of the mast, a socket secured to the upper end of the mast, a pin mounted in the socket, U-shaped bolts extending through the socket and through the mast, and a bearing on the frame for the reception of the pivot-pin, substantially as described.

7. The combination in a derrick, of a frame, a mast, a boom pivoted to the mast, a step-bearing for the lower end of the mast, a socket at the upper end of the mast, said socket having a vertical opening, a pivot-pin mounted in the opening, U-shaped bolts securing the socket to the mast, said socket having projections surrounding each bolt and entering the mast, and a bearing secured to the frame of the derrick by U-shaped bolts, said bearing arranged to receive the projecting pivot of the mast, substantially as described.

8. The combination in a derrick, of a mast, an A-frame, strut-legs, a socket secured to the A-frame, U-shaped bolts securing the socket to the said frame, a pin projecting above the A-frame, gooseknecks carried by the strut-legs through which the said pin passes, the pin also acting as a support for the sheave-strap at the upper end of the A-frame, substantially as described.

9. The combination in a derrick, of a main frame, wheels supporting the said frame, one set of wheels being the driving-wheels, hoisting mechanism carried by the frame and geared to the said driving-wheels, an A-frame at the forward end of the derrick, strut-legs leading from the upper portion of the A-frame to the rear of the main frame, a transverse beam on the A-frame, a short mast pivoted to the said beam, a foot-block secured to the lower end of the mast having a pivot, a step-bearing for the pivot, said step-bearing and foot-block having an open center, sheaves carried by the foot-block and by the step-bearing, a boom pivoted to the foot-block, an upwardly-extending internal flange in the step-bearing projecting up into the opening in the pivot and forming an annular cavity for retaining a lubricant, a plate forming a dust-guard secured to the foot-block, a socket at the upper end of the mast and secured thereto by U-shaped bolts, a pivot-pin mounted in the socket and projecting above the mast, a bearing in the cross-bar of the main frame for the reception of the pivot, the upper and lower pivots of the mast being in line, a bull-wheel carried by the mast, and braces extending from the mast to the rim of the bull-wheel, the said boom extending between the braces, substantially as described.

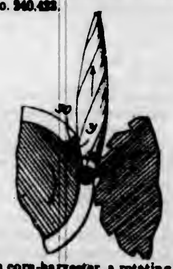
810,692. DOOR-SECURER. KNUD ANDERSON, Tacoma, Wash., and LARS PEDERSON, Manitowoc, Wis., assignors of one-third to Hans Meyer, Manitowoc, Wis. Filed June 23, 1905. Serial No. 266,634.

Claim.—1. A device of the character described, comprising a plate or bar effective for engagement with the door-jamb and having two series of adjusting-holes, and a sleeve or cuff slidable upon said bar or plate and effective for engagement with the door, and equipped with a shiftable spring-detent for coaction with said holes.

2. A device of the character described, comprising a lug-equipped plate or bar member having two series of adjusting-holes alternating each other, and a lug-equipped sleeve member arranged for insertion thereon and having a spring-detent for engagement with either of said series of holes.

3. A device of the character described, comprising a lug-equipped plate or bar having adjusting-holes therein alternating one with the other, and a lug-equipped sleeve or cuff member having in its forward edges extended notches or recesses, and equipped with a spring detent or dog sprung through a hole in said sleeve member and effective to be laterally shifted in said notches from one to the other of said series of adjusting-holes.

810,693. CORN-HARVESTER. DANIEL H. ANTHONY, Akron, Iowa, assignor of one-half to Emery H. Mellen, Akron, Iowa. Filed Jan. 10, 1905. Serial No. 240,423.



Claim.—1. In a corn-harvester, a rotating snapping-roll having rigid spiral ribs with faces inclined inward in the direction in which the roll revolves.

2. In a corn-harvester, a rotating snapping-roll having rigid spiral ribs, each with a shoulder *x* and faces each inclined inward in the direction in which the roll revolves and toward said shoulder *x*.

3. In a corn-harvester, a rotating snapping-roll having rigid spiral ribs with shoulders *x* the faces of said ribs inclined inward toward said shoulders *x* in the direction in which the roll revolves.

4. The combination in a corn-harvester, of gatherers a pair of rotating rolls inclined backward and upward and having on their surfaces rigid spiral wedge-like ribs, the faces of the ribs on the adjacent sides of the rolls inclined in reverse directions.

5. The combination in a corn-harvester, of gatherers, ribbed snapping-rolls, one of decreasing diameter toward the end, and bearings adjustable to permit the rolls to be set with their axes diverging, with the adjacent working parts at either end parallel.

6. The combination in a corn-harvester, of a pair of ribbed snapping-rolls one of increasing diameter toward the center, and movable bearings whereby the rolls are relatively adjustable to permit them to be set with their adjacent working parts parallel at either end.

7. The combination with the roll supported in fixed bearings, of a second roll, a movable bearing for the latter roll, a spring tending to carry the latter roll toward the first, and a fly-wheel geared with the movably-supported roll, to exert a lateral thrust upon the latter.

8. The combination with a gatherer of a rotary stalk-lifter, a support upon which the lifter rotates freely under the friction of the stalks.

9. The combination with a gatherer, of a rotary conical lifter and a support upon which the lifter rotates freely under the friction of the stalks.

10. The combination with a gatherer of a rotary lifter contracted toward the outer part and mounted to turn freely under friction of the stalks on a shaft extending upward and outward from the gatherer.

11. The combination with a gatherer having gathering-chains of a rotary lifter supported to rotate freely under friction of the stalks.

12. The combination with the rolls of a corn-harvester, of means for producing an air-blast and for directing it against the stalks of corn adjacent to the point where it is engaged by the rolls.

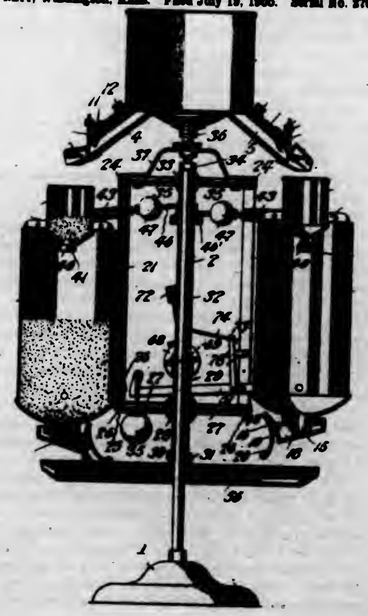
13. The combination with the rolls of a corn-harvester of means for producing an air-blast and for directing the same at different points against the stalks of corn and toward the rolls.

14. The combination with a corn-harvester having a stripping device, of means for producing an air-blast and for directing it against the stalks of corn adjacent to the point where it is engaged by the stripping device.

15. The combination with the rolls of a corn-harvester of a shaft approximately parallel to the rolls and carrying an eccentric push-bar, and means for rotating said shaft.

16. The combination with the roll K, its shaft and movable supporting-bracket, and the fly-wheel and shaft, of intermeshing gears on the fly-wheel shaft and roll-shaft.

810,694. AUTOMATIC WEIGHING-MACHINE. EDGAR C. ARNETT, Washington, Kans. Filed July 19, 1905. Serial No. 270,206.



Claim.—1. In a weighing apparatus, the combination with a feed device, of weighing mechanism embodying a load-receiver provided with an entrance-chamber, a valve controlling the flow of material therefrom to the receiver, means for closing said valve when the receiver has made a partial traverse, a valve controlling the discharge of material from the receiver, and means for opening the discharge-valve when the controlling-valve is closed, cutting off the feed when the receiver starts on its final traverse and maintaining the discharge-valve open and opening the controlling-valve in the return movement of the receiver.

2. In a weighing apparatus, the combination with a feed device, of weighing mechanism embodying a load-receiver provided with an entrance-chamber, a valve for governing the feed of material to the said entrance-chamber, a valve controlling the feed of material from the entrance-chamber to the receiver, a valve controlling the discharge of the material from the receiver, and automatic mechanism for controlling said valves to feed material to the receiver until the same is partially filled and cut off the flow from the entrance-chamber to said receiver, to open the discharge-valve on the final traverse of the receiver, and to close the discharge-valve when the receiver reaches the limit of its return movement.

3. In a weighing apparatus, the combination of a frame, upper and lower swinging scale-supports, a receiver pivoted to said supports and having a shifting connection with the upper support permitting it to have a preliminary downward movement independent thereof, a supplementary receiver opening into and movable with the first-named receiver, a valve controlling the discharge of material from said supplementary receiver, said valve being controlled by the upper support and brought to closing position during the preliminary downward movement of the main receiver and feeder for supplying material to the supplementary receiver, a valve controlling said feeder, a valve controlling the discharge of the material from the main receiver, and means for opening the discharge-valve upon the final traverse of the main receiver and simultaneously closing the feed-valve and closing the discharge-valve and opening the feed-valve at the limit of the return movement of the receiver.

4. In a weighing apparatus, the combination with a valve-controlled feeder, of a weighing-receiver provided with an entrance-chamber adapted to discharge thereinto and to receive the material from the feeder, a valve controlling the discharge of material from the receiver, a valve controlling the discharge of the material from the entrance-chamber to the receiver, pivoted weight-controlled supports for the receiver, one of said supports controlling the valve of the chamber, and means for opening the discharge-valve when the receiver reaches the limit of its weighing movement and closing the feed-valve and reversely operating said valves when the receiver returns to its normal position.

5. In a weighing apparatus, weighing mechanism embodying a receiver having two communicating chambers, a feeder adapted to discharge in one chamber for delivery to the other chamber, means for cutting off the flow of the material from the latter-named chamber when a certain proportion of the load is delivered therein, means for cutting off the feed of the material to the other chamber when the balance of the load is received therein, and means for discharging the load.

6. In a weighing apparatus, weighing mechanism embodying a main receiver and a supplementary receiver adapted to discharge thereinto, a feeder adapted to discharge into the supplementary receiver, means for cutting off the feed from the supplementary receiver to the main receiver when the latter has received a certain proportion of the load, means for cutting off the feed from the feeder to the supplementary receiver when the latter receives the balance of the load, and means for discharging the material from said receiver.

7. In a weighing apparatus, weighing mechanism embodying main and supplementary receivers, a feeder adapted to feed material to the supplementary receiver for delivery to the main receiver, means for cutting off the feed of the material from the supplementary receiver to the main receiver when the latter has received a certain proportion of the load, means for cutting off the feed of the material to the supplementary receiver when the latter has received the balance of the load, a discharge device, and means for controlling said discharge device to permit of the discharge of the material from both receivers.

8. In a weighing apparatus, a feed device, weighing mechanism embodying main and supplementary receivers, said supplementary receiver being adapted to receive the material from the feeder and discharge the same into the main receiver, a valve automatically operated when the main receiver has received a portion of the load to prevent the further delivery of the material from the supplementary receiver thereto, a valve for stopping the feed of the material to the supplementary receiver when the latter has received the balance of the load, a discharge-valve upon the main receiver, and means for alternately opening and closing the feeder and discharge-valve at the limits of the movements of the receivers.

9. In a weighing apparatus, a feeder, weighing mechanism embodying a main and a supplementary receiver, said supplementary receiver adapted to receive the material from the feeder and discharge the same into the main receiver, the weighing mechanism being adapted to permit said receivers to have a preliminary and a final traverse in its weighing movement, means for cutting off the feed of the material from the supplementary receiver to the main receiver when the receivers reach the limit of their preliminary traverse, means for cutting off the feed of the material from the feeder to the supplementary receiver when the receivers reach the limit of their final traverse, and means for automatically controlling the feeder and opening and closing the main receiver, when the receivers reach the limit of their weighing and return movements.

10. In a weighing apparatus, the combination of a feeding device, a plurality of weighing mechanisms, each embodying a main and a supplementary receiver, the supplementary receiver being adapted to receive the material from the feeder and discharge into the main receiver, a valve for closing the supplementary receiver when the main receiver has received a certain proportion of the load, a valve for cutting off the feed of the material to the supplementary receiver when the latter has received the balance of the load, a valve for controlling the discharge of the material from the main receiver, and means for alternately operating the valve to control the feed of the material to and governing the actions of the weighing mechanisms.

11. In a weighing apparatus, weighing mechanisms, each embodying a main and a supplementary receiver, said supplementary receiver being adapted to receive the material from the feeder and discharge the same into the main receiver, the weighing mechanism being adapted to permit each main and supplementary receiver to have a preliminary and final traverse in its weighing movement, means for cutting off the flow of the material from the supplementary receiver to the main receiver when the latter has received a portion of the load, means for cutting off the flow of the material from the feeder to the supplementary receiver when the latter has received the balance of the load, means for discharging the material from the main receiver when said receivers reach the limit of their final traverse, and automatic means for controlling the aforesaid means to permit alternate operations of the weighing mechanisms, said automatic means being provided with compensating mechanism to permit the discharge means of each weighing mechanism to remain open until the receivers reach the limit of their return movement.

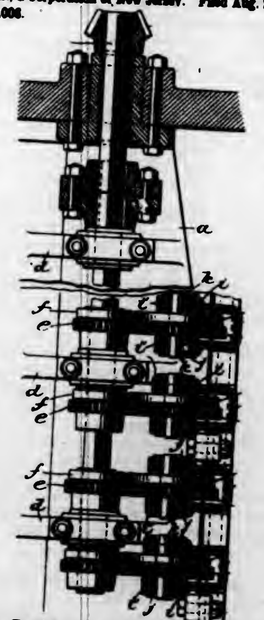
12. In an automatic weighing apparatus, the combination with a feeder, of weighing mechanism embodying a frame, main and supplementary receivers, said supplementary receiver being adapted to receive the material from the feeder and discharge the same into the main receiver, pivoted supports for the receivers, a shifting connection between the receivers and one of the supports to permit the receivers to have a preliminary downward movement independent of said support, a valve carried by said support and brought by such movement of the receivers into position to close the supplementary receiver, a valve controlling the feeder, a valve controlling the discharge of the material from the main receiver, and means for alternately operating said valves.

13. In an automatic weighing mechanism, a feeder provided with valve-controlled discharges, weighing mechanisms each comprising a main and a supplementary receiver and adapted to be alternately supplied from said discharges, the supplementary receiver being adapted to receive the material from the feeder and discharge the same into the main receiver, pivoted supports for said sets of receivers, valves for cutting off the flow from the supplementary to the main receivers when the latter have received a portion of the load, discharge-valves controlling the discharge of the material from the main receivers, and means for automatically controlling the feeder and discharge-valves, said means including compensating mechanism for maintaining the discharge-valves open upon the return movement of the receivers until an opening of the valves controlling the flow of material from the supplementary receiver is effected to permit said material to feed into the main receiver and discharge.

14. In a weighing apparatus, the combination of a hopper provided with valved feed-chutes, a supporting-frame, weight-controlled receivers pivotally mounted upon the frame, each receiver comprising a main receptacle provided with a discharge-outlet and a supplementary receptacle adapted to receive the material from the receptacle and discharge the same into the main receptacle, each receiver having a preliminary and a final traverse in its weighing movement, a valve operating to open and close the supplementary receptacle as the receiver moves above and below the limit of said preliminary movement, a discharge-valve for each main receptacle, operating means for alternately opening and closing the respective sets of valves, and shifting mechanism for actuating said operating means, said shifting mechanism being alternately operated by the receivers and adapted to permit the discharge-valve of each receiver to remain open until the controlling-valve of the supplementary receptacle is opened and the material in said receptacle is discharged.

15. In a weighing apparatus, the combination of a hopper provided with valved feed-chutes, a supporting-frame, weight-controlled receivers pivotally mounted upon the frame, each receiver comprising a main receptacle provided with a discharge-outlet and a supplementary receptacle adapted to receive the material from the receptacle and discharge the same into the main receptacle, each receiver having a preliminary and a final traverse in its weighing movement, a valve operating to open and close the supplementary receptacle as the receiver moves above and below the limit of said preliminary movement, a discharge-valve for each main receptacle, operating means for alternately opening and closing the respective sets of valves, a shifting device for alternately opening and closing the respective sets of valves, and trips actuated by the receivers to alternately operate said shifting device, said trips and shifting device being cooperatively constructed to permit the discharge-valve of each receiver to remain open until the controlling-valve of the supplementary receptacle is opened and the material in said receptacle is discharged.

810,695. **TENSION MECHANISM FOR WIRE-FENCE MACHINES.** AXEL F. BACKLIN and IDOFF RELUND, Worcester, Mass., assignors to The American Steel & Wire Company of New Jersey, Worcester, Mass., a Corporation of New Jersey. Filed Aug. 21, 1905. Serial No. 275,006.



Claim.—1. Tension mechanism for wire-fence machines, comprising a shaft, feed-rolls thereon, a series of pivoted levers each having a feed-roll thereon coöperating with a corresponding feed-roll on the shaft, gears connecting the respective lever-supported feed-rolls with the shaft, and means for adjusting the pivoted levers relatively to said shaft to vary the tension on said rolls.

2. Tension mechanism for wire-fence machines, comprising a shaft, feed-rolls thereon, a series of pivoted levers each having a feed-roll thereon coöperating with a corresponding feed-roll on the shaft, gears connecting the respective pairs of rolls, and means for adjusting the pivoted levers relatively to the shaft to vary the tension on said rolls.

3. Tension mechanism for wire-fence machines, comprising a shaft, feed-rolls thereon, a series of pivoted levers each having a feed-roll thereon coöperating with a corresponding feed-roll on the shaft, gears connecting the respective lever-supported feed-rolls with the shaft, and a yieldable adjustable connection between each lever and the machine-frame to vary the tension on said rolls.

4. Tension mechanism for wire-fence machines, comprising a shaft, feed-rolls thereon, a series of pivoted levers each having a feed-roll thereon coöperating with a corresponding feed-roll on the shaft, a yieldable adjustable connection between each lever and the machine-frame to vary the tension on said rolls, and a cam device coöperating with each lever and the machine-frame to move said lever independently of said connection.

5. Tension mechanism for wire-fence machines, comprising a shaft, feed-rolls thereon, a series of pivoted levers each having a feed-roll thereon coöperating with a corresponding feed-roll on the shaft, a yieldable adjustable connection between each lever and the machine-frame to vary the tension on said rolls, and means independent of said connection for moving each of said levers to separate the corresponding rolls.

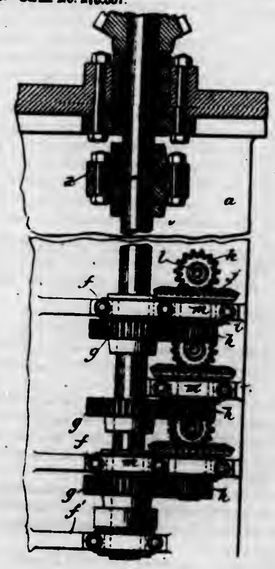
6. Tension mechanism for wire-fence machines, comprising a shaft, feed-rolls thereon, a series of pivoted levers each having a feed-roll thereon coöperating with a corresponding feed-roll on the shaft, gears connecting the respective lever-supported feed-rolls with the shaft, a bolt connected to each lever and passing through the machine-frame, and an adjustable spring connecting each bolt with the machine-frame, whereby the tension of said rolls may be varied.

7. Tension mechanism for wire-fence machines, comprising a shaft, feed-rolls thereon, a series of pivoted levers each having a feed-roll thereon coöperating with a corresponding feed-roll on the shaft, a bolt connected to each lever and passing through the machine-frame, an adjustable spring connecting each bolt with the machine-frame to vary the tension of said rolls, and a cam-lever pivoted to each lever and coöperating with the machine-frame to move said lever in opposition to the spring-and-bolt connection.

8. Tension mechanism for wire-fence machines, comprising a series of driving feed-rolls, a coöperating series of driven feed-rolls, and pivoted adjustable bearings for varying the distance between the axes of the respective series of rolls, whereby said rolls may be replaced by other rolls of different diameters.

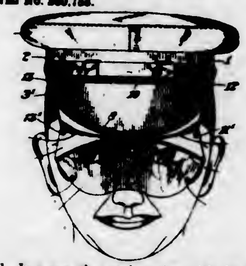
9. Tension mechanism for wire-fence machines, comprising a series of driving feed-rolls, a coöperating series of driven feed-rolls, and pivoted levers supporting the latter series of rolls, whereby the distance between the axes of the respective series of rolls may be varied to permit rolls of different diameters to be substituted.

810,696. **DRIVING MECHANISM FOR COILER-SPINDLES OF WIRE-FENCE MACHINES.** AXEL F. BACKLIN and IDOFF RELUND, Worcester, Mass., assignors to The American Steel & Wire Company of New Jersey, Worcester, Mass., a Corporation of New Jersey. Filed Aug. 21, 1905. Serial No. 275,007.



Claim.—Coiler-spindle-driving mechanism for wire-fence machines, comprising a vertical driving-shaft receiving an intermittent rotatory motion from the main shaft of the machine, a series of coiler-spindles, a series of spur-gears on said driving-shaft corresponding in number to the coiler-spindles, stub-shafts mounted upon the machine-frame adjacent to the respective coiler-spindles, a pinion and a bevel-gear on the respective ends of the stub-shafts, and a bevel-pinion on each of the coiler-spindles, the bevel-pinion on the respective coiler-spindles meshing with the corresponding bevel-gear on the stub-shafts, and the pinion on the respective stub-shafts meshing with the corresponding spur-gear on the driving-shaft.

810,697. CAP. LOUIS BALSAM, New York, N. Y. Filed May 17, 1905. Serial No. 260,726.



Claim.—1. In a cap, the combination with the vizor, of an eye-protector of transparent material and a bellows connection between the front edge of said vizor and the front edge of said protector, whereby the protector is adapted to be pulled down from the rear, substantially as described.

2. In a cap, the combination with the vizor, of an eye-protector of transparent material, a bellows connection between the front edge of said vizor and the front edge of said protector, whereby the protector is adapted to be pulled down from the rear, and means for limiting the downward movement of the protector, substantially as described.

3. In a cap, the combination with the vizor, of an eye-protector of transparent material and a bellows connection between the vizor and protector consisting of a folded strip of flexible material one edge secured along the front edge of the vizor and the other edge secured along the front edge of the protector, whereby the protector is adapted to be pulled down from the rear, substantially as described.

4. In a cap, the combination with the vizor, of an eye-protector of transparent material, a bellows connection between the vizor and protector consisting of a folded strip of flexible material one edge secured along the front edge of the vizor and the other edge secured along the front edge of the protector, whereby the protector is adapted to be pulled down from the rear, substantially as described and for securing it in raised position, substantially as described.

5. In a cap, the combination with the vizor, having a hole at each end, of an eye-protector, a bellows connection between the vizor and protector and a cord running round the front of the cap, passing through the holes in the vizor and its ends secured to the ends of the protector, whereby the downward movement of the protector is limited and it may be secured in raised position, substantially as described.

810,698. RAILWAY-TIE. JAMES BARRY, Seattle, Wash., assignor of one-fourth to Louis D. Bodum, Seattle, Wash., and one-eighth to Edward J. Brennan, St. Paul, Minn. Filed July 28, 1905. Serial No. 272,121.

Claim.—1. A railway-tie comprising an I-beam, having a rail-receiving countersink, and flanges for engaging the rail-flanges.

2. A railway-tie comprising an I-beam having a rail-receiving countersink forming a seat for the flange of the rail, and locking means for engaging the rail.

3. A railway-tie comprising an I-beam, having rail-receiving depressions forming seats, flanges partly overhanging the depressions, plates engaging the rail and held by said flanges, and locking means engaging the rails.

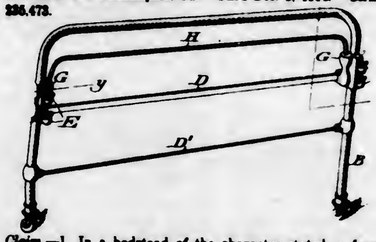
4. A railway-tie comprising a metallic I-beam, having rail-receiving depressions forming seats for the flanges of the rails, flanges overhanging the depressions, wedge-plates between said overhanging flanges, arranged to impinge against the rail-web, and locking means engaging the rail.

5. A railway-tie comprising an I-beam, having rail-receiving depressions, said depressions forming seats for the rail-flanges, an elongated shoulder projecting away from the plane of the beam and engaging the rail, said shoulder located on the outside of the rail, and made integral with the I-beam, and means on the inside of the tie coöperating with the shoulder on the outside of the tie for locking the rail in position, and plates interposed between the rail and flange for securing the rail to its seat.

6. A railway-tie comprising an I-beam having rail-receiving depressions forming seats for the flanges of a rail, flanges partly overhanging the depressions and arranged to clamp the rail, one of said flanges being extended and bent upward to form a fish-plate for rail-joints, and means for securing the same to the rails.

7. A railway-tie comprising a metallic I-beam having rail-receiving depressions, forming seats for the flanges of a rail, a shoulder extending away from the plane of the tie arranged on the outer side of the rails, and engaging the rails, flanges on the inside of the rail coöperating with the outside flanges, wedges between the flanges and seat, and an integral plate on the outside of the rail arranged to be bent upward and secured to the abutting rails.

810,699. END PIECE FOR METALLIC BEDSTEADS. WILLIAM F. BIRNSTEIN, Philadelphia, Pa. Filed Dec. 5, 1904. Serial No. 235,673.



Claim.—1. In a bedstead of the character stated, a frame, a sleeve on the leg thereof, a vertically-extending boss on said sleeve, bed-bottom-supporting means and brace-receiving means on said sleeve at right angles to each other, a cross-bar and a brace, said bar being intermediate of the top rail of said frame and said brace and the latter having an end secured to said sleeve, said cross-bar having on an end, a depending limb which enters said boss and rises therefrom.

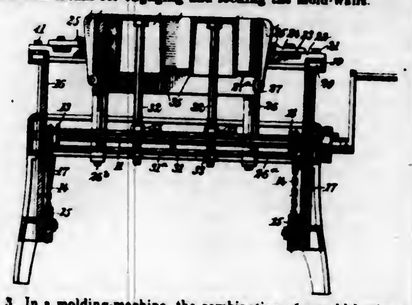
2. As an improved article of manufacture, an end piece for a metallic bed, the same comprising in a single element a sleeve having upon one side a hook, a horizontal recess to receive an end of a brace and a bore to receive the leg, and a vertically-extending boss with an opening to receive a depending limb of a cross-bar.

3. In a bedstead, a foot-piece, a brace, a bow-shaped cross-bar between said piece and brace and an end piece comprising in a single element a sleeve, a hook on a side thereof, a vertically-extending boss, a bore in said sleeve to receive the leg of the foot-piece, a horizontal recess to receive an end of said brace and an opening in said boss to receive a depending limb of said cross-bar.

810,700. MOLDING-MACHINE. HERMAN BRUNER, Alpena, Mich. Filed Apr. 19, 1905. Serial No. 256,297.

Claim.—1. In a molding-machine, the combination of a frame having ways thereon, a bridge adjustably mounted on said ways, a mold bottom plate supported by said bridge, said bottom plate being perforated, a core mounted to move through the perforations in the bottom plate, mold-walls movably mounted with respect to the bottom plate, means for moving the core, and means connected with said core-moving means for moving the mold-walls and locking them.

2. In a molding-machine, the combination of a frame having inwardly-extending ways longitudinally mounted thereon, a plurality of bridges adjustably mounted on said ways, sills mounted on said bridges, a bottom plate supported by said sills, side plates pivotally mounted on the sills, said bottom and side plates constituting a mold, a frame movably mounted on the frame of the machine, a core mounted on said frame and adapted to pass through the bottom plate longitudinally, and cross-bars adjustably mounted on said movable frame and located outside the mold, said bars being provided with means for engaging and locking the mold-walls.



3. In a molding-machine, the combination of a mold having a wall provided with a projection constituting a partition for the mold pivoted at the lower end thereof, said wall being provided with a projection having a face gradually diverging upwardly from its lower end, a bar mounted adjacent to said wall and provided with a roller for engaging said surface, means for reciprocating the bar and a movable core having a projection constituting a partition for the mold.

4. The combination of a mold consisting of a bottom plate, side walls and end walls, said side and end walls being pivoted to the bottom plate and provided with inclined surfaces on their exteriors, said surfaces diverging upwardly from the walls, a reciprocable frame mounted upon the outside of the mold and provided with rollers engaging said inclined surfaces and comprising two pairs of bars adjustably secured together, and means for reciprocating said frame.

5. The combination of a mold consisting of a bottom plate, side walls and end walls, said side and end walls being pivoted to the bottom plate and provided with inclined surfaces on their exteriors, said surfaces diverging upwardly from the walls, a reciprocable frame mounted upon the outside of the mold and provided with rollers engaging said inclined surfaces, means for reciprocating said frame, said frame being provided with a downwardly-extended projection, a pulley mounted on said projection, a shaft provided with a pulley, and a flexible member secured to the pulley on the shaft passing under the first-named pulley and secured at the other end in a stationary position.

6. In a molding-machine, the combination of a mold having movable walls, a movable frame having means for locking said walls in closed position, said frame being provided with a depending projection, a pulley rotatably mounted on said projection, a shaft, a pulley on said shaft, a flexible member having one end secured in stationary position passing under the pulley on the projection and secured to the pulley on the shaft, a ratchet-wheel on the shaft, and a pawl for engaging the ratchet-wheel.

7. In a molding-machine, the combination of a mold having movable walls, a movable frame for moving and locking said walls, and means for moving said frame; said means comprising a downwardly-extending projection on the frame, a pulley on said projection, a flexible connection having one end secured in a stationary position and passing under said pulley, a shaft upon which said connection is adapted to be wound, and means on the shaft for rotating it and taking up the flexible connection.

8. In a molding-machine, the combination of a mold having movable walls, a stationary perforated bottom board, a core adapted to pass through the perforation in the bottom board, a standard on which the core is mounted, said standard being provided with screw-threads, a movable table for supporting the standard, said table having a series of perforations through any one of which the standard is adapted to project, and nuts for securing said screw-threaded portion of the standard to the table in adjusted positions.

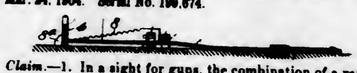
9. In a molding-machine, the combination of a mold having movable walls and a perforated bottom board, a core adapted to pass through the perforation in the bottom board, a standard on which the core is mounted, a table for supporting the standard, means for adjustably securing the standard to the table, and means for simultaneously moving the core through the perforation in the bottom board and locking the mold-walls in closed position.

810,701. FLANGE FOR PIANO-ACTIONS. FREDERICK C. BILLINGS, Rockford, Ill. Filed Apr. 14, 1905. Serial No. 255,550.

Claim.—1. In a flange of the class described, a single piece of resilient sheet metal, bent double and having a bearing formed at the point where said piece is bent, the ends of said piece being provided with open-ended slots, and the end of one of the arms formed by the bend being turned at right angles to the body portion; substantially as specified.

2. The combination with the center rail of a piano-action in which is formed a horizontally-arranged slot, of a flange constructed of a single piece of material, a bearing formed at the upper end of said flange, there being a slot at the lower end of the flange for the reception of the retaining-screw that enters the rail, and a lip integral with the lower end of the flange which enters the groove in the rail; substantially as specified.

810,702. GUN-SIGHT. GILBERT L. BLACK, Minoa, N. Y. Filed Mar. 24, 1904. Serial No. 199,674.



Claim.—1. In a sight for guns, the combination of a raised bar extending across the gun-barrel and having a slot extending through the same lengthwise of the barrel, a spring-bar adapted to fit said slot and containing a recess, a spring-catch engaged within the recess of said bar, and a sight carried by the free end of the said spring-bar.

2. As an improvement in sighting means for guns the combination of a longitudinal spring-bar the forward end secured to a gun and the rear end having a slot, a plate secured to the rear end of said bar and having an upper open sight and a lower central recess, a wedge having a slot and longitudinally movable in the bar-slot and the central recess of the plate, a plate slidable on said spring-bar and having a bar engaging the slot in said wedge beneath said spring-bar, whereby when said plate is moved back and forth the wedge will partake of its movement and raise and lower the sight-plate, substantially as described.

3. As an improvement in sighting means for guns, the combination of a longitudinal spring-bar the forward end secured to a gun and the rear end having a slot, a plate secured to the rear end of said bar and having an upper open sight and a lower central recess, a wedge having a slot and longitudinally movable in the bar-slot and the central recess of the plate, and a plate slidable on said spring-bar and engaging the slot in said wedge, whereby when said plate is moved back and forth the wedge will partake of its movement and raise and lower the sight-plate, substantially as described.

810,703. GUN-SIGHT. GILBERT L. BLACK, Minoa, N. Y. Filed Jan. 22, 1904. Serial No. 190,115.

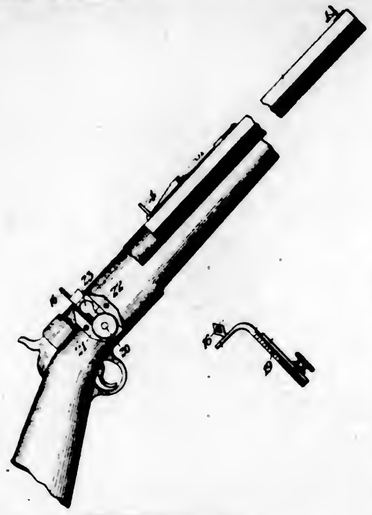
Claim.—A rear sight for guns comprising a hollow guide member adapted to be secured to the side of the gun and having an elongated vertical slot provided with a circular enlargement, at its upper end, a bar mounted to slide vertically within the guide member and having a threaded hole in its lower end, an arm extending laterally from its upper end over the gun and a sighting member carried by said arm and means for holding said bar at different elevations consisting of a screw having a button on one end adapted to bear against the outer face of the guide member, an enlarged threaded end adapted to be inserted through the circular enlargement of the elongated slot in the guide member and into engagement with the threaded hole in

said bar and bear against the inner face of the guide member and a reduced neck adapted to fit in the vertical slot in the guide member, substantially as described.

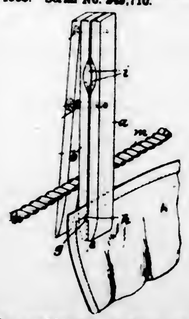
810,705. BLOCK-SIGNAL SYSTEM FOR ELECTRIC RAILWAYS. ABRAM L. BOWER, Boyertown, Pa. Filed Jan. 10, 1903. Serial No. 138,698.

4. In a block-signal system, the combination with a section of [illegible] at its other end with the opposite [illegible]

said bar and bear against the inner face of the guide member and a reduced neck adapted to fit in the vertical slot in the guide member, substantially as described.



810,704. CLOTHES-PIN. ANDREW G. BORNEMAN, Athenia, N. J. Filed Mar. 13, 1905. Serial No. 249,710.



Claim.—1. The combination of three separate members and means for connecting them together in face-to-face relation to each other for movement to and from each other, said means limiting the movement of the outer two of said members away from each other, substantially as described.

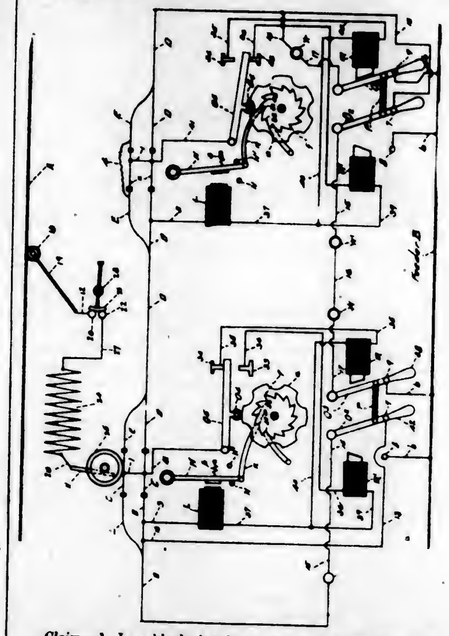
2. The combination of three separate members, means for connecting them together at one end, and means for maintaining said members in face-to-face relation to each other located between the ends of said members, said last-named means limiting the movement of the outer two of said members away from each other, substantially as described.

3. The combination of three separate members, a headed device connecting said members together at one end and mounted in one and penetrating the other two of said members, and means for maintaining said members in face-to-face relation to each other located between the ends of said members, said means limiting the movement of the outer two of said members away from each other, substantially as described.

4. The combination of three separate members, means for securing them together at one end, and a headed screw located between the ends of said members and screwed into one and penetrating the other two of said members, substantially as described.

5. The combination of three separate members, means for securing them together at one end, a headed screw located between the ends of said members and screwed into one and penetrating the other two of said members and a spring interposed between two of said members, substantially as described.

810,705. BLOCK-SIGNAL SYSTEM FOR ELECTRIC RAILWAYS. ABRAM L. BOWER, Boyertown, Pa. Filed Jan. 10, 1903. Serial No. 138,696.



Claim.—1. In a block-signal system for electric railways, the combination with the track divided into blocks or sections, of insulated rail-sections between adjacent blocks, a feed-wire extending along the railway, a circuit-changing switch at the end of each block, main signal-wires extending from one of said switches to the other, said switches arranged to connect the main signal-wires terminating therein alternately to the feed-wire and to the common return of the power-circuit, magnets to operate said switch, and electrical means coöperating with a car to energize said magnets alternately as successive cars arrive upon the insulated track-section at the end of block, substantially as described.

2. In a block-signal system for electric railways, the combination with the track divided into blocks or sections, of insulated rail-sections between adjacent blocks, a feed-wire extending along the railway, a circuit-changing switch at the end of each block, main signal-wires extending from one of said switches to the other, said switches arranged to connect the main signal-wires terminating therein alternately to the feed-wire and to the common return of the power-circuit, magnets to operate said switch, a circuit divided into two branches, one of said magnets connected in each of said branches, a magnet connected in circuit common to both branches, means operated by said third magnet to energize said switch-operating magnets alternately as successive cars arrive upon the insulated track-section adjacent thereto, substantially as described.

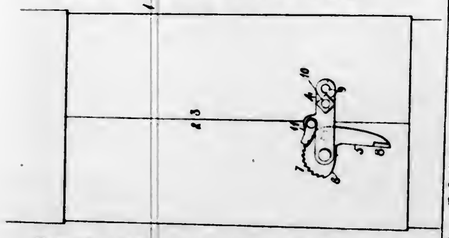
3. In a block-signal system for electric railways, the combination with the track divided into blocks or sections, of insulated rail-sections between adjacent blocks, a feed-wire extending along the railway, a circuit-changing switch at the end of each block, main signal-wires extending from one of said switches to the other, said switches arranged to connect the main signal-wires terminating therein alternately to the feed-wire and to the common return of the power-circuit, magnets to operate said switch, a circuit divided into two branches, one of said magnets connected in each of said branches, a magnet connected to circuit common to both of said branches and in circuit with the insulated rails, a movable contact device, means coöperating with the last-named magnet to bring said contact device into electrical connection with said branches alternately, electrical connection between said contact device and the adjacent insulated track-section, a trolley-wire and means to complete the circuit from the said trolley-wire to the said insulated track-section when a car arrives thereon, substantially as described.

4. In a block-signal system, the combination with a section of track, of traffic-controlling devices in connection with a line-wire terminating in a switch, which coöperates alternately with a branch of the feed-wire and the return-conductor; two magnets in relation to the switch; a divided circuit, one of said magnets being included in each branch of the circuit; a switch-arm arranged to be included alternately in the branches of said divided circuit, a ratchet-wheel; a pawl for said ratchet-wheel actuated by an armature, a third magnet included in both branch circuits for operating the armature, a break-wheel provided with a notched periphery, said break-wheel arranged for operation by said ratchet-wheel, the second switch-arm resting upon the notched or indented periphery of the break-wheel, operative devices for energizing and deënergizing the circuit, together with the rails forming the return-conductors, and an insulated rail-section connected to the switch controlling the branch circuits, substantially as described.

5. In a block-signal system, a series of blocks, insulated rails between the blocks, divided circuits terminating in the rails, each circuit having an insulated rail for one terminal, a magnet included in and controlled by both branch circuits, said magnet operating a commutating device controlling each circuit, the commutating device serving to connect the branch circuits alternately with the main circuit, an additional magnet in each branch of the divided circuit, switch-arms in relation to these magnets, line-wires terminating in a switch at each end, said switch being adapted to coöperate alternately with branches of a current-supply wire and the return-conductor, together with traffic-controlling devices adjacent to the turnouts, and devices for energizing and deënergizing the divided circuits, substantially as described.

6. In a block-signal system for electric railways, the combination with a series of blocks, signal-lamps connected with line-wires terminating in switches at the turnouts, a feed-wire having a branch at each turnout, an earth-conductor having a branch at each turnout, the switches coöperating with the branches of the feed-wire and the return-circuit alternately, a main local circuit with two branch circuits at each turnout, a magnet included in and controlled by both branch circuits, said magnet operating an armature, pawl, ratchet-wheel, and a commutating device serving to connect the branch circuits alternately with the main local circuit, a magnet in each branch circuit and in operative relation to the switches and adapted to move them alternately forward and backward, a trolley-conductor, and means coöperating with a car to complete a circuit from said trolley-conductor through one of said local branch circuits at a time, when the car arrives at a given section of track, substantially as described

810,706. STOVEPIPE. CHARLES A. BOYER and DANIEL C. PECK, Marengo, Ill. Filed Oct. 15, 1904. Serial No. 228,592.



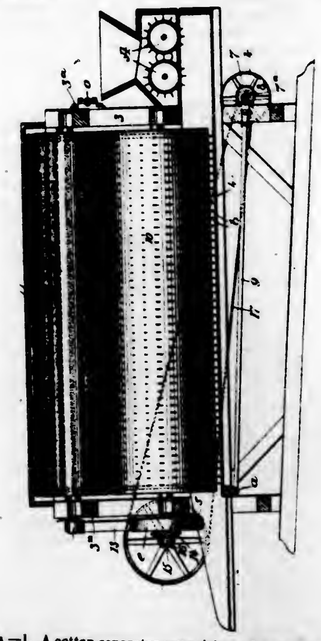
Claim.—1. A pipe-section having two lengthwise overlapping edges, a peripherally-toothed element having a connection with said section near one edge thereof, a strap or bar having an eccentric connection at one end with said toothed element and at its other end connected to the opposite edge of the pipe-section, and a dog adapted to engage said peripherally-toothed element to lock the same against movement in one direction.

2. A pipe-section having two lengthwise overlapping edges, a peripherally-toothed element having a pivotal connection with the said section near one edge thereof, a bar eccentrically connected at one end to said toothed element and at its other end to the opposite edge of the pipe-section, and a dog carried by said bar adapted to engage the teeth on the said toothed element.

3. A pipe-section having two lengthwise overlapping edges, a peripherally-toothed element having a pivotal connection with the said section near one edge thereof, a bar eccentrically connected at one end to said toothed element and having an adjustable connection at its other end with the opposite edge of the pipe-section, and a dog carried by said bar adapted to engage the teeth on the toothed element.

4. A pipe-section having two lengthwise overlapping edges, a peripherally-toothed cam-lever pivotally connected to said section at one edge thereof, a bar eccentrically connected at one end to said cam-lever and having a detachable connection at its other end to the opposite edge of the pipe-section, and a dog carried by said bar adapted to engage the teeth on the cam-lever.

810,707. GRABOT-MACHINE. JAMES D. BRASHER and DANIEL O. SULLIVAN, Vicksburg, Miss., assignors, by mesne assignments, of one-half to Bernard Siani, Rolling Fork, Miss. Filed July 7, 1904. Serial No. 215,673.



Claim.—1. A cotton-separator comprising a drum having teeth, a drum having brush-tufts, said teeth and tufts being in contact, a shaker located below the toothed drum, and means for simultaneously rotating the drums.

2. A cotton-separator comprising a toothed drum, a brush-drum, a shaker below the toothed drum, means for rotating the drums in opposite directions, with the teeth and brushes thereof in engagement with each other, and means for simultaneously agitating the shaker.

3. A cotton-separator comprising a toothed drum, a brush-drum located above said toothed drum and parallel therewith, a shaker located below the toothed drum, means for rotating the drums, and means for agitating the shaker.

4. A cotton-separator comprising a drum having inclined teeth, a brush-drum engaging with said teeth, means for rotating the toothed drum in the direction of the inclination of the teeth, means for rotating the brush-drum in the opposite direction at a greater circumferential speed, a shaker below the toothed drum, and means for agitating the shaker.

5. A cotton-separator comprising a drum having inclined teeth, a drum having brush-tufts, said drums being located in proximity to each other, a curved shaker located immediately below said toothed drum, means for rotating said toothed drum in the direction of inclination of its teeth, means for rotating said brush-drum in the opposite direction at a greater circumferential speed, and means for simultaneously agitating said shaker.

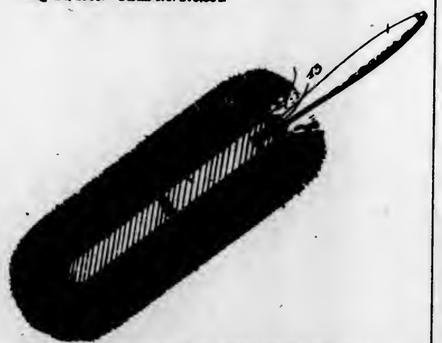
6. A cotton-separator comprising a drum having inclined teeth, a drum having brush-tufts, means for rotating said first-named drum

in the direction of inclination of its teeth for the purpose of collecting fibrous material, means for rotating said drum having brush-tufts in the opposite direction, with the brush-tufts in engagement with the teeth and for removing the fibrous material from the teeth, an inclined screen below the first-named drum, and means for agitating said screen to cause solid material thereon to be fed in the direction of the inclination of the screen.

7. In a separator, the combination with a frame, and a shaker on the lower portion of the frame, of a toothed drum rotatable on the frame over the shaker, a brush-drum rotatable on the frame above the toothed drum, means for rotating the drums in opposite directions, and means for shaking the shaker.

8. In a separator, the combination with a frame, a transversely-curved shaker on the frame, and an eccentric device adapted to agitate the shaker, of a drum rotatable longitudinally on the frame above the shaker, inclined teeth on the shell of said drum, a drum rotatable on the frame above the toothed drum and having brush-tufts thereon that pass between the teeth of the lower drum, pulleys on the drum-shafts, a crossed belt connecting said pulleys, and gearing adapted to rotate the lower-drum shaft.

810,708. **BRUSH.** SAMUEL H. BRISTOW, Monticello, Iowa. Filed Aug. 24, 1905. Serial No. 275,504.



Claim.—The herein-described brush comprising the head, tapered at one end, having the screw-socket at the opposite end and provided at its center with the transverse screw-socket, the brush having the skin covering of the size and shape to receive the head and provided with openings at one end and at one side to register with the screw-sockets of the head, and further provided at the end opening with an elastic contracting-ring to draw said end on the corresponding end of the head, and the handle having the screw-threaded end to engage either of the sockets in the head, and the shoulder to bear against the cover.

810,709. **SAFETY-RAZOR.** SAMUEL G. BROSIUS, Washington, D. C. Filed Dec. 13, 1905. Serial No. 291,694.

Claim.—1. In a safety-razor, a handle having a shield mounted thereon, a razor-blade having two cutting edges, and a member for holding the razor-blade movable longitudinally of the handle to lift and swing the blade free of the shield, the said shield being provided with a guard protecting the idle cutting edge of the said razor-blade, substantially as described.

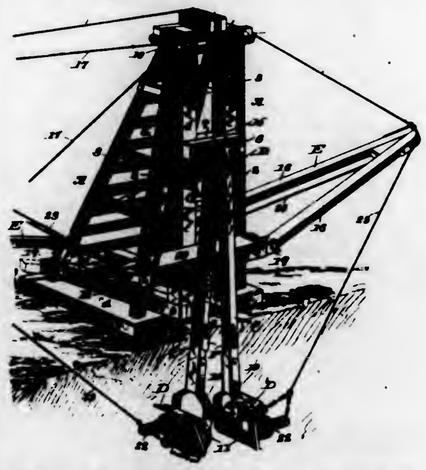
2. In a safety-razor, a handle, a shield secured thereto and provided with razor-blade stops in combination with a razor-blade resting on the said shield and pressing against the said stops, the said razor-blade being thickened at the corners of its cutting edge, substantially as described.

3. In a safety-razor, a handle, a shield secured thereto and provided with razor-blade stops in combination with a razor-blade, having two cutting edges, resting on the said shield the said razor-blade being thickened at the corners of its cutting edges, substantially as described.

4. In a safety-razor, a handle, a shield secured thereto and provided with razor-blade stops, in combination with a razor-blade provided with two cutting edges having their corners thickened, the said blade being adapted to present either cutting edge for use, substantially as described.

5. In a safety-razor, a handle having a shield mounted thereon, a razor-blade having two cutting edges, and a member for holding the razor-blade movable longitudinally of the handle, the said shield being provided with a guard protecting the idle cutting edge of the said razor-blade, substantially as described.

810,710. **DREDGE.** ANDREW J. BURCHAM, Kelso, Wash. Filed Oct. 30, 1905. Serial No. 285,121.



Claim.—1. The improved dredging and scraping machine comprising a frame having a vertical guide, a block adapted to slide vertically on said guide, beams pivoted to said block, and diggers pivoted to the lower ends of the same, the beams being adapted to swing laterally, booms pivoted to the sides of the frame, and means for locking the swinging beams therewith when the diggers are elevated, and means for raising and lowering the booms with the diggers and also the beams and for raising the diggers to the position required for discharging their load, substantially as described.

2. The improved dredger comprising a frame having vertical guides, a block adapted to slide vertically between them, beams pivoted to the block, and diggers pivoted to the lower ends of the same and provided with arms arranged at an angle to their digging and scraping edges, a hoisting and lowering rope connected with the digger-beams and the aforesaid block, booms pivoted to the sides of the frame, and means for raising and lowering them, ropes or chains connected with the diggers and connected with the outer ends of the booms, whereby the diggers may be hauled laterally outward and upward, and means for locking the digger-beams with the boom for supporting the diggers while their load is being discharged, substantially as described.

3. The combination, with a suitable frame having vertical guides and a block adapted to slide on the guides, of beams pivoted to such block, and diggers pivoted in the lower ends of the beams, a hoisting and lowering rope passing over the top of the frame and having a loop extending through slots in the digger-beams at a point some distance below their pivots, and means for hauling the diggers proper laterally, substantially as described.

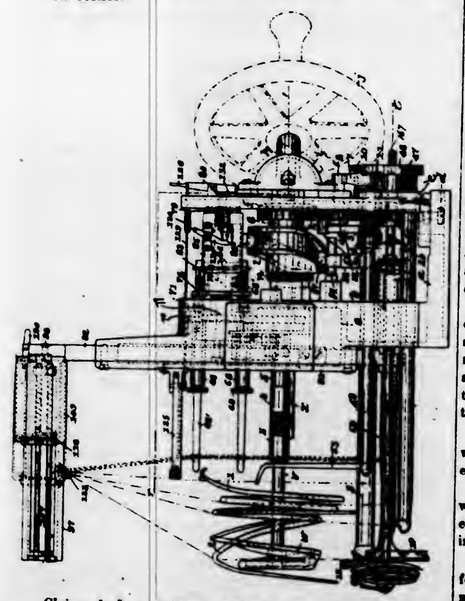
4. In a dredger of the class indicated, the combination, with a suitable frame, of pivoted beams made vertically adjustable, diggers connected with their lower ends, and means for hoisting the digger-beams and diggers, and also hauling the latter outwardly from each other, substantially as described.

5. In a dredger of the class indicated, the combination, with a suitable frame and a member adapted to slide vertically thereon, of a beam pivoted to such member, and a digger attached to the lower end of the beam, and means for raising the said member, the beam, and the digger, and for hauling the digger laterally, substantially as described.

6. In a dredger of the class indicated, the combination, with a frame and a lateral boom, of a pivoted and vertically-adjustable beam and a digger attached thereto, a dog pivoted to each of the digger-beams and adapted to slide over and engage a boom, and means for raising the digger-beams and digger and for hauling the digger laterally, and for adjusting the boom higher or lower, substantially as described.

7. In a dredger of the class indicated, the combination, with the pivoted swinging beam, of a digger proper comprising a curved plate having perforations in its middle portion, and side bars extending outwardly therefrom, substantially as described.

810,711. **WARP-TWISTING-IN MACHINE.** AMOS CALLEBOW and ADRIAN D. ABRIANCE, Brooklyn, N. Y., and ANTON DUPPLER, Jersey City, N. J., assignors to Warp Twisting-In Machine Company, New York, N. Y., a Corporation of New York. Filed Dec. 24, 1904. Serial No. 238,199.



Claim.—1. In a twisting mechanism, the combination of a frame, a rotary twisting member journaled in said frame, a normally fixed twisting member coactive with said rotary member, a shaft mounted in said frame and carrying the latter member, and means for adjusting said shaft longitudinally, substantially as described.

2. In a twisting mechanism, the combination of a frame, a rotary twisting member journaled in said frame, a normally fixed twisting member coactive with said rotary member, a spring-pressed shaft mounted in said frame and carrying the latter member, a spring normally acting on said shaft to move said latter member away from the other member, and means for adjusting said shaft longitudinally against the tension of its spring, substantially as described.

3. In a twisting mechanism, the combination of coactive twisting members one of which is adapted to wipe against the other to effect the twisting and the other of which is movable to and from the other, and adjustable means for holding the member which is movable to and from the other in a given position relatively to the other member, substantially as described.

4. In a twisting member for a twisting mechanism, a bracket and a pad removably mounted in said bracket, substantially as described.

5. In a twisting member for a twisting mechanism comprising members one of which is adapted to wipe against the other, a bracket and a pad detachably interlocked, the one of them having a projection engageable with the other to limit their relative movement past each other under the thrust of the other member of the twisting mechanism, substantially as described.

6. In a twisting mechanism, a twisting member comprising two plates, one of which carries the other and the other of which forms the twisting-pad, one of said plates having headed studs and the other having openings receiving said studs, substantially as described.

7. In a twisting mechanism, the combination of two members one of which is movable against the other to effect the twisting, one of said members comprising a support and a pad yieldable in said support to permit the various portions thereof to assume relatively different distances from the plane of operation of the other member of the twisting mechanism, substantially as described.

8. In a twisting mechanism, a twisting member comprising two plates detachably secured together and one of which carries the other and the other of which forms the twisting-pad, and cushioning means interposed between said plates, substantially as described.

9. The combination of the frame, a uniting mechanism, means for holding the threads while being operated upon, means for effecting the delivery of the threads to the uniting mechanism, and a fixed thread-concentrator located close to the uniting mechanism, substantially as described.

10. In a machine for twisting together and thus uniting threads or other filaments, the combination of the frame, a twisting mechanism, means for holding the threads while being operated upon, means for effecting the advance of the threads to the twisting mechanism, and a fixed thread-concentrator located close to the twisting mechanism and having a thread-engaging portion disposed obliquely to the line of advance of the threads, substantially as described.

11. In a machine for twisting together and thus uniting threads or other filaments, the combination of the frame, a twisting mechanism, means for holding the threads while being operated upon, means for effecting the advance of the threads to the twisting mechanism, a thread-detent located close to the twisting mechanism, and a thread-cutting means located in operative proximity to said detent, substantially as described.

12. In a machine for twisting together and thus uniting threads or other filaments, the combination of the frame, a twisting mechanism, means for holding the threads while being operated upon, means for effecting the advance of the threads to the twisting mechanism, a fixed V-shaped thread-concentrator located close to the twisting mechanism, and a thread-cutting means located in operative proximity to the concentrator, substantially as described.

13. In a mechanism for advancing the threads to be joined toward the twisting mechanism of a twisting-in machine, a fork having elastic tips forming the terminals thereof, substantially as described.

14. In a mechanism for advancing the threads to be joined toward the twisting mechanism of a twisting-in machine, a fork having elastic tips forming the terminals thereof and having thread-receiving bends formed therein, substantially as described.

15. The combination of a frame, a uniting mechanism, a means for advancing the threads successively to the uniting mechanism, a means for holding the threads comprising a thread-clamping mechanism normally movable in substantially the same direction as that of said threads toward the uniting mechanism, a thread-detent, and means for detaching the portion of the threads held by said holding means at a point between said detent and the uniting mechanism, substantially as described.

16. The combination of a frame, a uniting mechanism, and a means for holding the threads of the two warps comprising separate clamping means, one for each warp, movable independently in the direction of movement of the threads toward the uniting mechanism, substantially as described.

17. In a machine for twisting together and thus uniting threads or other filaments, the combination of the frame, a twisting mechanism, means for holding the threads while being operated upon, and a means, located in proximity to the twisting mechanism, for displacing out of the way of said twisting mechanism each united thread and keeping it separated temporarily from other threads, substantially as described.

18. In a machine for twisting together and thus uniting threads or other filaments, the combination of the frame, a twisting mechanism, means for holding the threads while being operated upon, and

a revoluble spiral located in proximity to the twisting mechanism, and adapted to displace out of the way of said twisting mechanism the united threads, substantially as described.

19. The combination, with a frame, a thread-uniting means, means for holding the threads, means for effecting a relative movement between said thread-uniting and thread-holding means whereby to bring the threads to be united under the influence of said uniting means, a driving element, and power-transmitting means connecting said driving element and the uniting and advancing means, of means for effecting a break in the operative continuity of said power-transmitting means, said means being itself controlled by the advancing threads, substantially as described.

20. The combination, with a frame, a thread-uniting means, means for holding the threads, means for effecting a relative movement between said thread-uniting and thread-holding means whereby to bring the threads to be united under the influence of said uniting means, a driving element, and disconnective power-transmitting means connecting said driving element and the uniting and advancing means, of means for controlling the operative continuity of said power-transmitting means, said means being itself controlled by the advancing threads, substantially as described.

21. The combination, with a frame, a thread-uniting means, means for holding the threads, means for effecting a relative movement between said thread-uniting and thread-holding means whereby to bring the threads to be united under the influence of said uniting means, a driving element, and power-transmitting means connected to said driving element and the uniting and advancing means, of means for effecting a break in the operative continuity of said power-transmitting means comprising devices normally arranged to break the operative continuity of said power-transmitting means and other devices actuated by intact threads for moving said first-named devices out of position to break the continuity of said power-transmitting means, substantially as described.

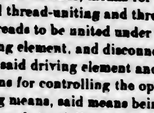
22. The combination of a frame comprising a horizontal guideway, a mechanism for successively uniting the threads of warps, a carriage supporting said mechanism and movable on said guideway, and means for advancing said carriage on the guideway comprising a rotary device having frictional contact with said guideway, substantially as described.

23. The combination of a frame comprising a horizontal guideway, a mechanism for successively uniting the threads of warps, a carriage supporting said mechanism and movable on said guideway, means for advancing said carriage on the guideway comprising a rotary device bearing against said guideway, and means for clamping said device against the guideway, substantially as described.

24. The combination of a frame comprising a horizontal guideway, a mechanism for successively uniting the threads of warps, a carriage supporting said mechanism and movable on said guideway, a lever projecting across said guideway on the side thereof opposite to said device, and a cam for pressing said lever against the guideway, substantially as described.

25. In a mechanism for separating threads or other filaments, the combination, with a frame and with thread-sustaining means, the threads being adapted to be disposed in two sets of which the threads of the one intersect those of the other at predetermined intervals, of a revoluble hook-bar spacing, and adapted to alternately hold back the one and then the other of, said series of threads and thus successively free the intersecting threads, and a rod coöperating with said hook-bar to maintain the cross in the threads and having one end free and projecting in substantially the same direction as said hook-bar, substantially as described.

810,712. **ARTIFICIAL DENTURE.** JOHN M. CARD, Olean, N. Y. Filed July 10, 1905. Serial No. 269,100.



Claim.—1. A process of making dental plates which consists in forming a model and fastening it to the articulator, then conforming a metal base to the model, articulating the teeth on the ridge of the metal base, and finally applying a gum-colored labial coating in semiliquid form upon the labial surface.

2. A process of making dental plates which consists in forming a model and fastening it to the articulator, then conforming a metal base to the model and perforating the ridge of said base, next setting the teeth in a plastic holding-piece upon the perforated ridge of the metal base, and finally applying a labial coating of gum-colored rubber in semiliquid form upon the labial side of the model.

3. A process of making dental plates which consists in forming a model and fastening it to the articulator, then conforming a metal base with a perforated rim to the model, next setting up the teeth in a plastic holding-piece upon the perforated portion of the metal base, applying a rubber finishing-strip about the supports for the teeth at the lingual side thereof, and finally applying a labial coating of gum-colored rubber in a semiliquid form over the labial surface of the model and in and about the teeth at the labial sides thereof.

4. A process of making dental plates which consists in forming a model and fastening it to the articulator, then shaping a metal plate to the model, next coating the model with a thin rubber solution, then applying a rubber sheet over both the labial and lingual surfaces of the model, next applying a metal base upon the rubber sheet, articulating the teeth upon the ridge of the metal plate, then applying a continuous strip of dental rubber about the ridge of the plate at the lingual side of the teeth, and finally applying a gum-colored labial rubber coating in semiliquid form on the labial surface of the model and in and about the teeth at the labial sides thereof.

5. A dental plate consisting of a metal base having retaining-holes in the ridge thereof, artificial teeth articulated upon and anchored to the perforated ridge of the base, a continuous rubber finishing-strip extending about the ridge of the plate at the lingual sides of the teeth and over the fastenings thereof, and a gum-colored labial coating extending in and about the teeth at the labial sides thereof.

810,713. **ARTIFICIAL DENTURE.** JOHN M. CARD, Olean, N. Y. Filed July 28, 1905. Serial No. 271,613.

Claim.—1. A process of making dental plates which consists in forming a model and fastening it to the articulator, then applying a dental-rubber sheet to the lingual surface of the model with the margins thereof extended upon the alveolar ridge, then setting the teeth in a holding-boss of waxable rubber, and then applying said waxable holding-boss upon the marginal edge of the dental-rubber sheet at the alveolar ridge.

2. A process of making dental plates which consists in forming a model and fastening it to the articulator, then applying a dental-rubber sheet to the lingual surface of the model with the margins thereof extended upon the alveolar ridge, then setting the teeth in a boss of waxable rubber, applying said waxable holding-boss over the alveolar ridge and labial surface and upon the marginal edge of the dental-rubber sheet, then removing the model from the articulator and finally vulcanizing and polishing the plate.

3. A process of making dental plates which consists in forming a model and fastening it to the articulator, then coating that portion of the model over which the plate and its connections are to extend with a rubber solution, applying a dental-rubber sheet upon the coating made by said solution, said sheet being arranged to extend over the lingual surface and upon the alveolar ridge, then setting the teeth in a boss of waxable rubber and applying the latter to the alveolar ridge and labial surface and upon the marginal edge of the dental-rubber sheet, finishing the exposed edges of the waxable rubber with dental rubber, and finally removing the model and vulcanizing and polishing the plate.

4. A process of making dental plates which consists in forming a model and fastening it to the articulator, applying a dental-rubber sheet to the lingual surface of the model, then arranging a labial strip of waxable rubber about the labial surface of the model in overlapping relation to the margin of the dental-rubber sheet on the alveolar ridge, next setting the teeth in a boss of waxable rubber and applying the latter over the joint between the lingual sheet and the dental strip, and finally removing the model and vulcanizing and polishing the plate.

810,714. **ART OF SIGNALING.** WILLIAM CHURCHILL, Corning, N. Y., assignor to Corning Glass Works, Corning, N. Y. Filed Oct. 17, 1905. Serial No. 283,134.

Claim.—1. As an improvement in the art of signaling, the combination of a lamp, a colored signal-glass adapted to receive a beam of light from the flame of said lamp, and an auxiliary lamp located in proximity to the said signal-glass, said auxiliary lamp being adapted to constantly exhibit a fixed color which by contrast shall intensify the color of the light visible through said signal-glass, substantially as set forth.

2. As an improvement in the art of signaling, the combination of a lamp, signal-glasses of varied colors adapted to be moved across or in front of and to receive a beam of light from the flame of said lamp, and an auxiliary lamp located in proximity to the said variedly-colored and movable signal-glasses, said auxiliary lamp being adapted to constantly exhibit a fixed color which by contrast shall intensify the color or hue of the signal-glass at the time resting in front of the flame of the lamp first mentioned, substantially as set forth.

3. As an improvement in the art of signaling, the combination of a lamp, signal-glasses of varied colors adapted to be moved across or in front of and to receive a beam of light from the flame of said lamp, and a lamp located in proximity to the said variedly-colored and movable signal-glasses, said lamp being adapted to constantly exhibit a fixed color which by contrast shall intensify the color or hue of the signal-glass at the time resting in front of the flame of the lamp first mentioned, substantially as set forth.

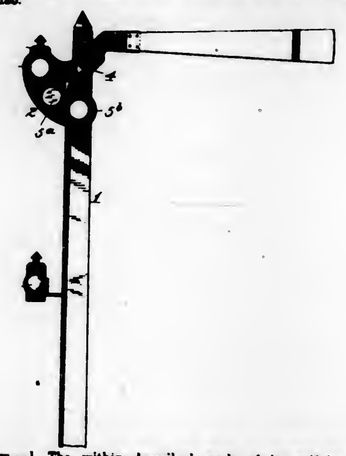
4. As an improvement in the art of signaling, a pole or support, a semaphore-lamp carried thereby, signal-glasses of varied colors pivotally mounted on said pole or support and adapted to be moved across or in front of and to receive a beam of light from the flame of said lamp, and a second lamp located in proximity to said variedly-colored and movable signal-glasses, said second lamp being adapted to constantly exhibit a fixed color which by contrast shall intensify the color or hue of the signal-glass at the time resting in front of the flame of the lamp first mentioned, substantially as set forth.

5. As an improvement in the art of signaling, the combination of a support, a lamp carried thereby, a spectacle pivotally mounted on said support having inserted therein signal-glasses of varied colors adapted to be moved across or in front of and to receive a beam of light from the flame of said lamp, and a second lamp located in proximity to the said variedly-colored and movable signal-glasses, said second lamp being adapted to constantly exhibit a fixed color which by contrast shall intensify the color or hue of the signal-glass at the time resting in front of the flame of the lamp first mentioned, substantially as set forth.

6. As an improvement in the art of signaling, a lamp with a clear lens, and an appertaining semaphore-arm and a spectacle, the latter containing variedly-colored roundels, combined with a second lamp with a clear lens, and an appertaining semaphore-arm and a spectacle, the latter containing roundels of the same color in each opening, thus producing a fixed color contrasting with the said variedly-colored roundels inserted in front of the first-mentioned lamp, substantially as set forth.

7. As an improvement in the art of signaling, a lamp and an appertaining semaphore-arm and a spectacle, the latter containing variedly-colored roundels, combined with a second lamp and an appertaining semaphore-arm and a spectacle, the latter having unfilled openings, a colored lens contrasting with the said variedly-colored roundels being inserted in said second lamp, substantially as set forth.

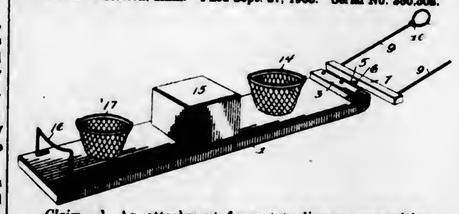
810,715. **METHOD OF INTENSIFYING THE COLORS OF SIGNAL-LIGHTS.** WILLIAM CHURCHILL, Corning, N. Y., assignor to Corning Glass Works, Corning, N. Y. Filed Oct. 17, 1905. Serial No. 283,135.



Claim.—1. The within-described mode of intensifying the colors and thereby increasing the efficiency of signal-lights for railroad, marine and other services, the same consisting in exposing in proximity to a signal-light of a given color a second light of constant color which shall by contrast produce the described effect, substantially as set forth.

2. The within-described mode of increasing the efficiency of signal-lights, the same consisting in exposing, at a predetermined distance from a signal-lamp displaying different colors for different indications, a second light exhibiting a color which shall, by contrast, intensify and render more vivid the several colors displayed, substantially as set forth.

810,716. **ATTACHMENT FOR POTATO-DIGGERS.** GEORGE E. CHUTE, Princeton, Minn. Filed Sept. 27, 1905. Serial No. 280,302.



Claim.—1. An attachment for potato-diggers, comprising a plank adapted to drag on the ground and having a cross-piece secured to the upper face thereof at the forward end of the plank, an evener-bar hitched centrally between its ends to said cross-piece, a pair of hitching-rods attached to said evener-bar, one near each end, and hitching-rings connected to the other ends of said hitching-rods.

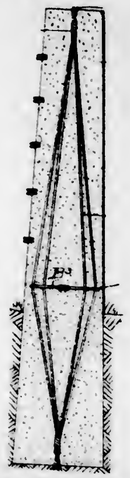
2. An attachment for potato-diggers, comprising a sled-like member in the form of a plank adapted to drag on the ground, a guard-fender supported thereby adjacent the rear end of the plank, an evener-bar pivoted centrally of its length to the forward end of the plank, a pair of hitching-rods having their one end pivotally attached to the evener-bar, and means carried by the other end of said rods for attaching them to a vehicle.

810,717. **TRUSS FOR CEMENT POSTS.** LEE CLARK, Garrison, Iowa. Filed Sept. 11, 1905. Serial No. 277,993.

Claim.—1. A truss comprising a plurality of longitudinally-extending wires twisted jointly upon each other at their opposite ends, and a spreader laterally disposed intermediate of the ends of said wires to retain them in separated position.

2. A truss comprising a plurality of longitudinally-extending wires twisted jointly upon each other at their opposite ends, a ra-

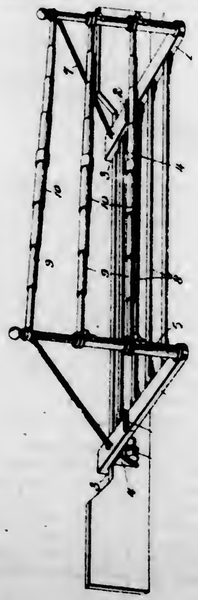
diating-spreader disposed intermediate of the ends of said wires to retain them in separated position and an extended supporting portion at each end of the longitudinal wires beyond the twisted portion thereof.



3. A truss comprising a plurality of longitudinally-extending wires twisted together at their opposite ends, a spreader disposed intermediate of the ends of said wires to retain them in separated position, an extended supporting portion at each end of the longitudinal wires beyond the twisted portion thereof and disposed at an angle to the body of the truss.

4. In a truss for plastic fence-posts, a plurality of longitudinally-extending wires connected together at their opposite ends, a spreader for said wires comprising a plurality of strands twisted together at their central portion and provided at their free ends with means for engaging the longitudinal wires.

810,718. **CRIB ATTACHMENT FOR BEDS.** WILLIAM R. CLARK, Chillicothe, Ohio. Filed Aug. 24, 1905. Serial No. 275,560.



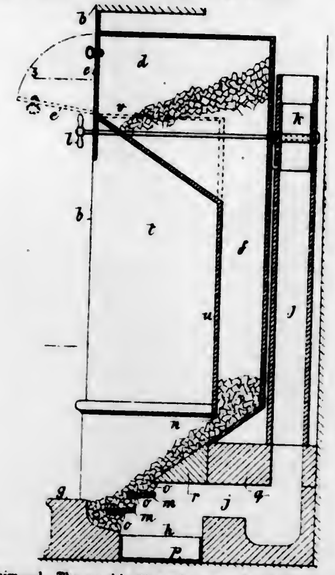
Claim.—1. A crib attachment for beds consisting of arms provided with clamps adapted to grip the frame of the bed, collapsible uprights located upon said arms, collapsible rails connecting said uprights and flexible strips connecting said arms together.

2. A crib attachment for beds consisting of arms provided with clamps adapted to grip the frame of the bed, collapsible uprights pivoted upon said arms, collapsible rails connecting said uprights and flexible strips connecting said arms together.

3. A crib attachment for beds consisting of arms composed of sections hinged together and provided with clamps adapted to grip the frame of the bed, collapsible uprights located upon said arms, collapsible rails connecting said uprights and flexible strips connecting said arms together.

4. A crib attachment for beds consisting of arms provided with clamps adapted to grip the frame of the bedstead, collapsible uprights located upon said arms, collapsible rails comprised of telescoping sections connecting said uprights, the end sections of said rails adapted to telescope into the middle sections thereof, and flexible strips connecting said arms together.

810,719. **OPEN FIREPLACE.** HOWARD C. CLEAVER, London, England. Filed Nov. 5, 1904. Serial No. 231,467.



Claim.—1. The combination of a forwardly-inclined apertured fire-grate exposed as to its upper surface; walls bounding said grate laterally; a kerb or fence at the lower extremity of the grate for limiting the descent of fuel thereover; and a flue adapted to withdraw the products of combustion from the space beneath the grate, substantially as specified.

2. The combination of a forwardly-inclined apertured fire-grate exposed as to its upper surface; walls bounding said grate laterally; a chute adapted to continuously deliver fuel by gravity to the upper extremity of the grate; a kerb or fence at the lower extremity of the grate for limiting the descent of fuel thereover; and a flue adapted to withdraw the products of combustion from the space beneath the grate, substantially as specified.

3. The combination of a forwardly-inclined apertured fire-grate exposed as to its upper surface; walls bounding said grate laterally; a chute adapted to continuously deliver fuel by gravity to the upper extremity of the grate; a kerb or fence at the lower extremity of the grate for limiting the descent of fuel thereover; a flue adapted to withdraw the products of combustion from the space beneath the grate; and a damper in said flue for regulating the draft, substantially as specified.

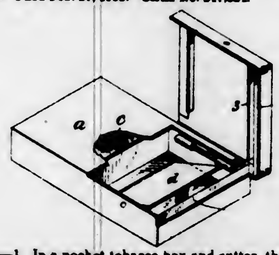
4. In an open fireplace, the combination of a forwardly-inclined apertured fire-grate exposed as to its upper surface and located at the lower part of the recess of a fireplace; a chute adapted to continuously deliver fuel by gravity to the upper extremity of the grate; a kerb or fence at the lower extremity of the grate for limiting the descent of fuel thereover; a flue adapted to withdraw the products of combustion from the space beneath the grate; a damper in said flue for regulating the draft; and a ventilating-door in the top wall of the recess of the fireplace, adapted to afford access therefrom to the flue, substantially as specified.

5. An open fireplace adapted to be located in an opening of a chimney comprising a body having a recessed front, the top wall of which is provided with openings having closures therefor, a fuel-supply chute at the rear of its recessed front, a downwardly and outwardly inclined grate in the lower part of the recess of the fireplace and onto the upper rear portion of which the chute discharges, a kerb for limiting the descent of the fuel over the grate, and a flue leading from beneath and behind the grate to a chimney, substantially as described.

6. An open fireplace adapted to be located in an opening of a chimney, comprising a body having a recessed front, the top wall of which is provided with openings, closures for said openings, a hopper in the upper part of the body, a chute leading from the hopper and extending downward at the rear of the back of the said recessed front, a downwardly and outwardly inclined grate in the lower part of the recessed front of the fireplace and upon which the chute discharges, a kerb for limiting the descent of the fuel over the grate, and a flue leading from beneath and behind the grate and extending upwardly in rear of the chute, substantially as described.

7. An open fireplace, adapted to be inserted in an opening in a chimney, comprising a body having a recessed front, the top wall of said recess being provided with openings, doors for said openings, a hopper in the upper part of the body, the bottom of the hopper being of less width than the top of the recess of the body, a chute extending from the hopper downward in rear of the back wall of the recess of the body, a grate formed of transverse bars spaced apart and arranged in step form and upon which the chute discharges, and a flue leading from beneath the grate and extending upwardly in rear of the chute.

810,720. **POCKET TOBACCO-BOX.** ISAAC E. COHEN, Bluefield, W. Va. Filed Feb. 27, 1905. Serial No. 247,594.



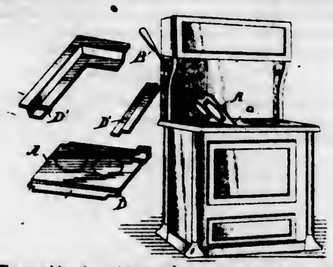
Claim.—1. In a pocket tobacco box and cutter, the body of the box having its forward end beveled to form a knife, a lid comprising a portion of the cover of the box and having its forward end beveled to form a knife to coöperate with the beveled edge of the body, whereby a shearing cut is made when the lid is closed, a spring at the rear end of the box, and a spring and false bottom in the forward end of the box adapted to throw the contents of the box up between the coöperating knives.

2. In a pocket tobacco box and cutter, a lid comprising a part of the cover of the box, and provided at its forward end with two coöperating knives, said knives being formed by the beveled forward edges of the cover and end of the box, a spring in the rear end of the box, and a spring and false bottom in the forward end of the box adapted to throw the contents of the box up between the coöperating knives.

3. In a pocket tobacco box and cutter, a lid comprising a part of the cover of the box, and provided at its forward end with two coöperating knives formed by the forward beveled edges of the cover and end of the box, combined with a spring at the rear end of the box, and another spring, vertically acting, together with a false bottom hinged midway of the box, the springs and false bottom acting to throw the contents of the box into contact with the coöperating knives.

810,721. **LIFT-PLATE.** HENRY C. COLE, Chicago, Ill., assignor to Cole Manufacturing Company, Chicago, Ill., a Corporation of Iowa. Filed May 11, 1905. Serial No. 260,615.

Claim.—1. The combination in a range substantially as herein described of the lift-plate provided at its outer edge with a socket arranged above the surface of the lift-plate and adapted to receive the inner end of a lifter, the bracket at the side of the range and having a vertically-elongated opening and provided at the side thereof with a series of scrolls providing hooks forming seats for the lifter, and the lifter passing through the said vertically-elongated opening in the bracket and fitting at its inner end in the socket of the lift-plate, and arranged to seat in the hooks of the bracket whereby the said lifter and the lift-plate may be held at any suitable angle, substantially as set forth.

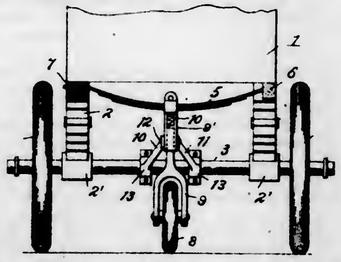


2. The combination with the lift-plate and the lifter adapted for interlocking engagement, of a bracket having a vertically-elongated opening through which the lifter is passed, and a hook or hooks for engagement by said lifter, substantially as set forth.

3. A range provided at one side of its top with an upright bracket having a hook or hooks for engagement by a lifter, a lift-plate forming a part of the top of said range and a lifter in the form of a rigid bar connected with said plate and adapted to seat in the hook or hooks in the bracket in securing the lift-plate when raised, substantially as set forth.

4. The combination of a lift-plate, a lifter and an upright bracket adjacent to the lift-plate and having an elongated opening or slot through which the lifter is passed, and a seat or seats in communication therewith for engagement by said lifter, substantially as set forth.

810,722. **VEHICLE ATTACHMENT.** HENRY F. COOK, Sag Harbor, N. Y. Filed June 13, 1905. Serial No. 265,080.



Claim.—1. In a device of the character described, the combination of a vehicle-body, supporting-wheels therefor and auxiliary wheels normally sustaining no portion of the weight of the vehicle-body but capable of sustaining it when one or more of the supporting-wheels leave the normal plane of the surrounding surface of the road-bed.

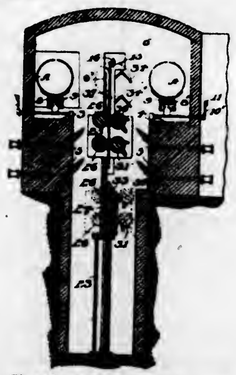
2. In a device of the character described, the combination of a vehicle-body, supporting-wheels therefor, springs connected to said vehicle-body and auxiliary wheels normally inoperative but adapted to sustain the load of said vehicle-body when one or more of the supporting-wheels are depressed by reason of leaving the normal plane of support.

3. In a device of the character described, the combination of a vehicle-body, suspension-springs, axles carrying supporting-wheels, springs connected to the vehicle-body and auxiliary wheels connected to said springs and to said axles said auxiliary wheels normally sustaining no portion of the weight of said vehicle but adapted to support the weight of the load of said vehicle-body when one or more of the supporting-wheels are depressed below the normal plane of support.

4. In a device of the character described, the combination of a vehicle-body, suspension-springs supporting said body, axles having supporting-wheels thereon, a wagon-spring connected to the body portion of the vehicle, a tubular guide connected to said spring having slidably arranged thereon a support carrying an auxiliary wheel, a compression-spring interposed between said wagon-spring and said support said auxiliary wheel being capable of sustaining the load of the vehicle when one or more of the supporting-wheels leave the normal plane of support.

5. In a device of the character described, the combination of a vehicle-body, supporting-wheels therefor, and an auxiliary wheel so arranged as to normally not take any of the load but adapted to increase in action under the influence of an abnormal strain on said vehicle-body, substantially as and for the purpose described.

810,723. APPARATUS FOR FLATTENING GLASS. JAMES CRAIG and ROBERT B. ROWAN, Parnassus, Pa. Filed Dec. 28, 1904. Serial No. 238,606.



Claim.—1. Glass-flattening apparatus comprising an oven, glass-holding means therein from which sheet-glass is adapted to be freely suspended, and means movable vertically within the oven for subjecting the freely-suspended glass to opposing pressures.

2. Glass-flattening apparatus comprising an oven, glass-holding means therein from which sheet-glass is adapted to be freely suspended, and glass-rolling mechanism movable vertically over the freely-suspended glass.

3. Glass-flattening apparatus comprising an oven, glass-holding means therein from which sheet-glass is adapted to be freely suspended, and opposing rolls movable vertically within the oven for operating on opposite surfaces of the freely-suspended glass.

4. Glass-flattening apparatus comprising an oven having a laterally-contracted lower portion, glass-holding means operative above the said contracted portion for sustaining the glass freely suspended therein, and heating means at opposite sides of said contracted portion.

5. Glass-flattening apparatus comprising an oven having a laterally-contracted lower portion, glass-holding means operative above said contracted portion for sustaining the glass freely suspended therein, heating means at opposite sides of the contracted portion, and vertically-movable glass-flattening means operative within said contracted portion.

6. Glass-flattening apparatus comprising an oven having a narrowed or contracted lower portion, a ledge within the oven above and at one side of the contracted portion, a glass-cylinder support above said ledge, and laterally-movable glass-suspending means adapted to engage the cylinder and move it laterally and sustain it above the contracted lower portion of the oven as it uncurls or straightens therein.

7. Glass-flattening apparatus comprising an oven, a glass-cylinder support at each side of the oven, the oven being unobstructed downwardly between the supports, and glass-suspending means adapted to sustain the glass when straightened within said downwardly-unobstructed portion of the oven.

8. Glass-flattening apparatus comprising an oven, glass-suspending means, opposing fixed and movable rolls within the oven for engaging opposite surfaces of the glass, and means for moving the rolls vertically over the suspended glass.

9. Glass-flattening apparatus comprising an oven, glass-suspending means, driven rolls within the oven for engaging one surface of the glass, rolls within the oven and movable toward and from the glass for engaging the opposite surface thereof, and means for causing all of the rolls to traverse the glass.

10. Glass-flattening apparatus comprising an oven, glass-suspending means, opposing rolls movable vertically over the surfaces of the glass, means for moving the rolls apart when in lowered position, and means operative when the rolls are raised for moving them into opposing relation.

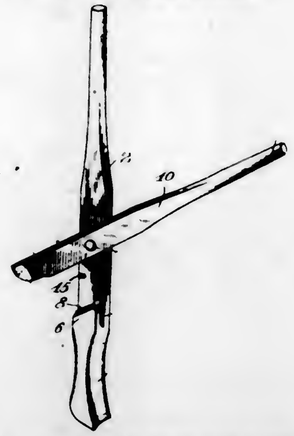
11. Glass-flattening apparatus comprising an oven, glass-suspending means, opposing fixed and movable rolls within the oven for rolling the opposite surfaces of the glass, the movable rolls being held in engagement with the glass by force of gravity and means for moving the rolls vertically over the suspended glass.

12. Glass-flattening apparatus comprising an oven, glass-suspending means, a movable roll-support within the oven, rolls fixed in said support for engaging one surface of the glass, and rolls movably mounted in the support and constructed and arranged to engage the opposite surface of the glass by force of gravity.

13. Glass-flattening apparatus comprising an oven, glass-suspending means, opposing rolls within the oven adapted to traverse the opposite surfaces of the glass, and means for varying the space between the opposing rolls.

14. Glass-flattening apparatus comprising an oven, a chamber at one side of the oven and separated therefrom by a vertical wall having a vertically-elongated opening, and glass-suspending means movable horizontally within the oven and chamber and through said communicating opening for sustaining the glass in either of said compartments.

810,724. WIRE-STRETCHER. CHARLES E. CROSBY, Gassaway, W. Va. Filed Aug. 14, 1905. Serial No. 274,144.

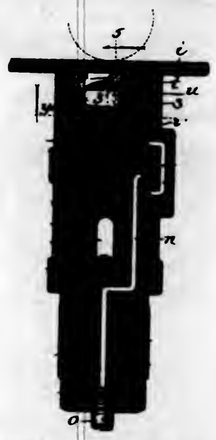


Claim.—1. A wire-stretcher comprising a lever having a handle at one end and an enlargement at its other end, said enlargement being formed with a toe at its outer end and a spaced angularly-disposed jaw at its inner end, a hand-lever pivoted upon said lever and having at one end a handle and at its opposite end an angularly-disposed jaw to coact with the first-mentioned jaw and a projecting tongue to enter the space between the first-mentioned jaw and the first-mentioned lever, substantially as described.

2. A wire-stretcher comprising a lever having a spaced angularly-disposed jaw adjacent to one end and a wire-receiving recess adjacent to said jaw, and a hand-lever pivoted upon said lever and formed with an inclined jaw to coact with the first-mentioned jaw and a projecting tongue to enter the space between the first-mentioned jaw and the first-mentioned lever, said hand-lever being adapted to swing across said wire-receiving recess to sever a wire placed therein, substantially as described.

810,725. BELL-RINGER. RICHARD M. CROSBY, Tacoma, Wash. Filed Aug. 2, 1905. Serial No. 272,293.

Claim.—1. In an apparatus of the class described, the combination of a fixed piston, a piston-cylinder slidably mounted thereon having a closed upper end forming a piston-chamber provided with an exhaust-passage leading therefrom one of such members having an inlet-passage leading to such piston-chamber, and means for opening and closing such inlet and exhaust passages.



2. In an apparatus of the class described, the combination of a piston, a piston-cylinder slidably mounted thereon having a closed upper end forming a piston-chamber provided with an exhaust-passage leading therefrom one of such members having an inlet-passage leading to such piston-chamber, and the other having an inlet-passage communicating with a source of fluid-supply such inlet-passages being adapted to be connected and disconnected by the movement of the cylinder with relation to the piston.

3. In an apparatus of the class described, the combination of a piston, a piston-cylinder slidably mounted thereon having a closed upper end forming a piston-chamber provided with an exhaust-passage leading therefrom one of such members having an inlet-passage leading to such piston-chamber and adapted to communicate with a source of fluid-supply, and a sleeve-valve mounted in the piston-cylinder and movable into and out of engagement with such exhaust and inlet passages.

4. In an apparatus of the class described, the combination of a piston provided with a fluid-inlet passage, a piston-cylinder slidably mounted thereon having a closed upper end forming a piston-chamber provided with an exhaust-passage leading therefrom and having an inlet-passage communicating with such piston-chamber and adapted to be moved with the cylinder into and out of connection with the inlet-passage in the piston, and means for opening and closing the exhaust-passage.

5. In an apparatus of the class described, the combination of a piston provided with a fluid-inlet passage, a piston-cylinder slidably mounted thereon forming a piston-chamber provided with an exhaust-passage leading therefrom and having an inlet-passage communicating with such piston-chamber and adapted to be moved with the cylinder into and out of connection with the inlet-passage in the piston, and a sleeve-valve slidably mounted in engagement with the inner wall of such cylinder and movable into and out of closed engagement with the exhaust and inlet passages in such cylinder.

6. In an apparatus of the class described, the combination of a piston, a piston-cylinder slidably mounted thereon provided with an upper portion closing the upper end and extending beyond the main body portion of such cylinder adapted to engage the bell-crank of a bell to be operated thereby such cylinder forming a piston-chamber having an exhaust-passage leading therefrom and one of such members having an inlet-passage leading into such piston-chamber, and means for opening and closing such inlet and exhaust passages.

7. In an apparatus of the class described, the combination of a piston, a piston-cylinder slidably mounted thereon forming a piston-chamber provided with an exhaust-passage leading therefrom one of such members having an inlet-passage communicating with such piston-chamber, and means for partially closing the admission-passage before the exhaust-passage is open during the stroke in one direction and movable into position to partially close the exhaust-passage during the return movement before the admission-passage is open.

8. In an apparatus of the class described, the combination of a fixed piston, a piston-cylinder slidably mounted thereon having a closed upper end forming a piston-chamber provided with an exhaust-passage, such piston and cylinder being provided with inlet-passages communicating with a source of fluid under pressure, and means for opening and closing such exhaust and inlet passages.

9. In an apparatus of the class described, the combination of a piston provided with an admission-passage communicating with a suitable source of fluid under pressure, a piston-cylinder provided with a closed upper end and an open lower end mounted upon such piston and having an exhaust-passage and an admission-passage adapted to communicate with such admission-passage in the piston when the cylinder is in one position and movable out of communication with such admission-passage when the cylinder is in a second position, and a sleeve-valve slidably mounted in such cylinder for covering and uncovering such exhaust and admission passages.

10. In an apparatus of the class described, the combination of a piston provided with a fluid-inlet passage and having an annular recess and an annular shoulder above and below such recess, a piston-cylinder in sliding engagement with such piston having a closed upper end and side walls forming a piston-chamber and provided with a passage in its side walls leading to such chamber and adapted to communicate with such inlet-passage in the piston, and a sleeve-valve mounted in the recess between the piston and cylinder-walls movable with the cylinder into and out of engagement with the shoulders upon the piston for opening and closing the fluid-passage.

11. In an apparatus of the class described, the combination of a fixed piston having a fluid-inlet passage and provided with an annular recess having annular shoulder portions forming the upper and lower ends of such recess, a cylinder closed at its upper end slidably mounted upon such piston forming a piston-chamber having a passage communicating with the space formed by such recess and provided with a passage having its lower end movable into and out of communication with the inlet-passage of the piston and its upper end opening into the recessed portion of the piston, and a sleeve-valve mounted in slidable engagement with the inner wall of such piston-cylinder and movable into and out of engagement with the upper end of such fluid-passage in the cylinder.

12. In an apparatus of the class described, the combination of a fixed piston having a fluid-inlet passage and provided with an annular recess having annular shoulder portions at the upper and lower ends of such recess, a cylinder closed at its upper end slidably mounted upon such piston forming a piston-chamber having a passage communicating with the space formed by such recess and provided with an exhaust-passage leading from the recess and an inlet-passage having its lower end movable into and out of communication with the inlet-passage of the piston and its upper end opening into the recessed portion of the piston, and a valve slidably mounted in the recess formed between the piston and the walls of the piston-cylinder and movable with the piston-cylinder into and out of engagement with the shouldered portions of the piston for opening and closing the inlet and exhaust passages in the cylinder.

13. In an apparatus of the class described, the combination of a piston and piston-cylinder mounted in sliding engagement with each other and provided with fluid inlet and exhaust passages, and means for partially closing the admission-passage before the exhaust-passage is open during the upward movement of the cylinder and movable into position to partially close the exhaust-passage before the admission-passage is open during the downward movement of the cylinder.

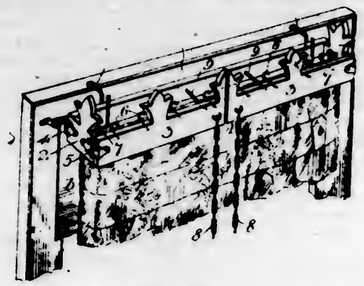
14. In an apparatus of the class described, the combination of a piston and piston-cylinder mounted in sliding engagement with each other and provided with fluid inlet and exhaust passages, and a piston-ring slidably mounted in engagement with the inner surface of the piston-cylinder movable into position to partially close the admission-passage before the exhaust-passage is open during the upward movement of the cylinder and movable into position to partially close the exhaust-passage before the admission-passage is open during the downward movement of the cylinder.

810,726. CURTAIN-HANGER. REBECCA J. CUMMINS, Greenville, Ohio. Filed Sept. 11, 1905. Serial No. 278,009.

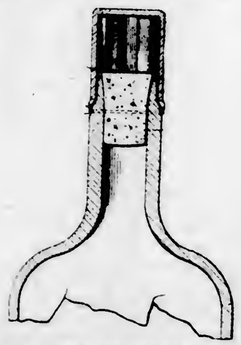
Claim.—1. A window-curtain fixture comprising a bar, means to detachably secure the same to a window, end pieces pivotally connected to the bar, and curtain-supporting arms pivotally connected to the end pieces, for the purpose set forth.

2. The herein-described window-curtain fixture, comprising the bar 1, the bracket a to detachably secure said bar to and space the

came from a window, the end pieces pivotally connected to the bar, and the curtain-supporting arms pivotally connected to the end pieces.



810,727. BOTTLE. JOHN M. CUTLER, Ukiah, Cal., assignor of one-half to John L. McNab, Ukiah, Cal. Filed Aug. 29, 1905. Serial No. 276,394.



Claim.—1. A bottle-neck provided with a thin breakable portion, and a breakable cap embracing the neck and the thin breakable portion thereof.

2. A bottle having its neck provided with an annular series of extensions, an annular thin breakable portion around the bases of the extensions, and a breakable cap embracing the extensions and the bottle-neck.

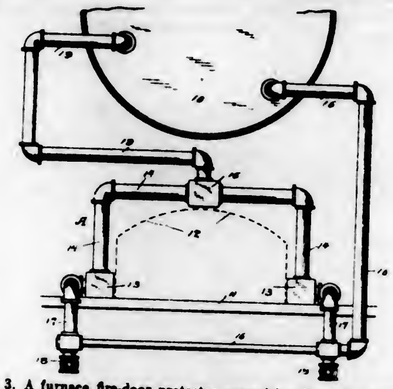
3. A bottle having its neck provided with an annular series of longitudinal extensions and a thin annular breakable portion around the bases of the extensions, an external annular shoulder upon the bottle-neck below the top thereof, said neck being provided with an annular series of longitudinal recesses intersecting the shoulder and the thin portion of the neck between the extensions, a stopper fitted within the bottle-neck, flexible elements extending across the top of the stopper downwardly through the recesses and around the bottle-neck beneath the shoulder thereof, and a breakable cap embracing the extensions and engaging the annular shoulder.

4. A bottle having its neck provided with a thin annular breakable portion and an external annular shoulder below the breakable portion, said breakable portion and shoulder being intersected by longitudinal recesses, a stopper fitted within the bottle-neck, flexible elements extending across the top of the stopper downwardly through the recesses and around the neck beneath the shoulder thereof, and a breakable cap embracing the breakable portion of the neck and engaging the annular shoulder.

810,728. FURNACE FIRE-DOOR PROTECTOR. BERNARD J. DALY, Waterbury, Conn., assignor to M. J. Daly and Sons, Incorporated, Waterbury, Conn., a Corporation of Connecticut. Filed Sept. 6, 1905. Serial No. 277,141.

Claim.—1. A furnace fire-door protector comprising lower headers, a plurality of pipes rising therefrom and extending inward and an upper central header with which said pipes connect.

2. A furnace fire-door protector comprising lower headers, a connection leading to said headers from the boiler, an upper central header, pipes rising from the lower headers and connecting with the upper header and a connection leading from the upper header to the boiler



3. A furnace fire-door protector comprising lower headers, a supply-pipe leading from the boiler, branch pipes leading from the supply-pipe to the headers, blow-off valves at the lower ends of the branch pipes, an upper central header, pipes rising from the lower headers and connecting with the upper header and a return-pipe leading from the upper header to the boiler.

810,729. SKIRT-SUPPORTER. HERBERT C. DRANE, Salt Lake City, Utah. Filed Aug. 10, 1905. Serial No. 273,861.

Claim.—1. A holder substantially as herein described, comprising two thin plates having at their ends the upper and lower jaws, one of the upper jaws of each plate having the inturned lip overlapping the opposite jaw of the other plate and elongated laterally and adapted to engage a shirt-waist and the lower jaws having their lips outturned and provided with inwardly-projecting teeth adapted to secure a skirt and to form fulcra whereby the pressing of the lips of the lower jaws toward each other will spread or open the upper jaws, the cross-plates connecting the jaws at the opposite ends of the holder, said cross-plates being secured together at their middles and spread or flared toward their ends, and the slides on said cross-plates and adapted for adjustment to close or release the end jaws, substantially as set forth.

2. A holder comprising a pair of plates and having at its ends upper jaws to engage a shirt-waist and lower jaws to secure a skirt, cross-plates between the opposite pairs of jaws, and slides operating on said cross-plates, substantially as set forth.

3. A holder provided at each of its opposite ends with a pair of opposing upper jaws and a pair of opposing lower jaws adapted to secure a shirt-waist and a skirt, substantially as described.

4. A holder provided at each of its opposite ends with upper jaws to secure a shirt-waist and with lower jaws to secure a skirt and provided between said jaws with means whereby they may be held inclosed position, substantially as described.

5. A holder provided with upper and lower jaws, the lower jaws being flared or spread apart at their lower edges and provided above said flared edges with inwardly-projecting teeth adapted to secure a skirt and to serve as a fulcrum in compressing the flared ends of the jaws for spreading the upper jaws, substantially as described.

6. A holder consisting of two plates similar in form and outline and provided at their ends with upper jaw-sections and lower jaw-sections and with cross-plates connecting their end portions, and means for securing these cross-plates together at their middles, and slides operating on the cross-plates between their middles and their end portions, substantially as described.

810,730. DINNER-BUCKET. HARRY J. DEBAR, Newport, Pa., assignor of one-half to Richard J. Overton, Freedom, Pa. Filed May 23, 1905. Serial No. 261,867.

Claim.—1. A dinner-bucket of the character described, comprising a main bucket member having air-inlets in the lower end, a burner detachably mounted therein, a food-holding pan shaped to project down into the main bucket and to be supported on the upper end thereof, a cover for fitting over the said food-holding pan and a supplemental pan or holder, of less length and width than the other holder, adapted to fit within the said other holder and having means for suspending it from the ends of the main bucket member over the heater when the said other holder is removed from the main bucket portion, the said cover having means for sustaining the said supplemental pan or holder on its under side, as set forth.

2. In a dinner-bucket, comprising a main bucket member, whose bottom is adapted to support a heater, a can or holder detachably supported within the upper end of the main bucket member and a cover for the said can or holder, a shallow pan of less width and length than the can or holder, a means on the cover for detachably supporting the shallow pan within said cover, said pan or holder having means for suspending it from the ends of the main bucket member when removed from said cover, said means being foldable over the said pan when not in use, substantially as shown and described.

3. In a dinner-bucket of the character described, in combination with a deep main bucket member, having its bottom constructed to detachably support a heater, a can or holder formed to be detachably supported on the upper end of the main bucket member to produce an air-tight closure, a second can or holder detachably suspendable within the other holder, a cover for fitting over said holders, a shallow pan adapted to fit in and form a cover for the second-mentioned holder or can and having means whereby it can be detachably suspended within the main bucket member over the heat whereby to form a frying-pan, as set forth.

4. The hereinbefore-described dinner-bucket, which consists of a deep bottom member, a heater removably mounted on the bottom thereof, a flared can or holder adapted to fit down into the bottom member and detachably rest in the upper edge thereof to form a closure member therefor, a second flared can or holder adapted to detachably fit into the other can and form a closure member therefor, a cover that fits over the two cans, and a shallow pan adapted to detachably fit into the top of the second can and form a closure member therefor, said shallow pan having means for detachably suspending it from the upper edge of the deep bottom member directly over the heater when the two aforesaid cans are removed therefrom, and means on the cover for detachably suspending the shallow pan therein, all being arranged substantially as shown and described.

5. In a dinner-bucket of the character described, in combination with the main or deep member and the heater located on the bottom thereof; a shallow pan of less width and length than the deep pan, means connected to the shallow pan for detachably suspending it from the upper edge of the deep member within said deep member directly over the heater and the cover for the deep pan, said cover having means for removably holding the shallow pan on its under side, for the purposes described.

810,731. HAULAGE SYSTEM. EVANDER ROSS, Rankin, N. C. Filed June 10, 1905. Serial No. 264,663.

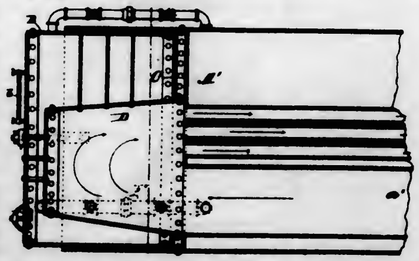
Claim.—1. In a system of the class described the combination with a main track and a switch-track, of rails pivoted to the rails of the switch-track for movement to lie at times at one side of the main track and at times above the rails thereof, and guide-rails disposed upon the rails of the main track and adapted for vertical movement at one end to bring said ends into and out of operative relation to the pivoted rails for the passage of a car from the main track to the pivoted rails and the switch-track.

2. In a system of the class described the combination with a main track and a switch-track, of pivoted rails communicating at one end with those of the switch-track and movable to lie with their other ends at times above the rails of the main track and at times out of such position, vertically-movable guide-rails arranged to lie at times wholly upon the rails of the main track and at times at one end only thereupon and with their other ends in alinement with the pivoted rails and means for moving the guide-rails.

3. In a system of the class described the combination with a main track and a switch-track, of a car disposed upon the main track, a cable extending longitudinally of the main track, means for moving the cable, a grip carried by the car and engaged with the cable, a spring arranged to hold the grip in operative position, means for holding the spring with the grip in operative position, said means being movable out of operative position and a finger located adjacent to the switch and adapted for engagement of the spring-holding means to move the latter into inoperative position.

4. The combination with a car, of a cable-grip therefor comprising a depending block, a spring-arm pivoted between its ends to the car, a block carried by one end of the arm and arranged for cooperation with the first-named block to clamp the cable therebetween, an angle-lever pivoted to the car and arranged to receive the other end of the spring thereagainst to hold the spring with its block in clamping relation to the first-named block, said angle-lever being movable upon its pivot to bring its arm out of engagement with the spring.

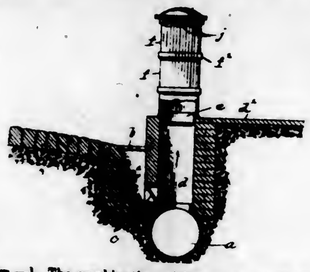
810,732. FEED-WATER HEATER. GUSTAF A. ERICKSON, ROBERT ERICKSON, and HILDUR ERICKSON, Fort Dodge, Iowa. Filed July 20, 1905. Serial No. 270,515.



Claim.—In combination with a steam-boiler the exterior shell of which extends rearwardly beyond the back end wall of the boiler.

a fire-chamber and return-flue that terminates at such end wall, of a feed-water heater having a water-surrounded fire-chamber such chamber being adapted to encompass the fire-chamber and the return-flues of the boiler, and means for clamping the feed-water heater against the end wall of the boiler; such clamping means comprising bolts attached to the boiler and a cross-bar with which the bolts engage, substantially as shown.

810,733. **VENTILATOR FOR SEWER AND OTHER PIPES.** GEORGE W. EVANS, Tuxedo Park, Md. Filed May 29, 1905. Serial No. 262,719.



Claim.—1. The combination with a sewer, drain or other pipe containing noxious gases, of an inlet provided with a flap; a vent-passage from said sewer, drain or pipe; and a vent and purifier comprising a plural number of sections or chambers resting one upon the other—each section having an internal shelf and a vent-passage, the said vent-passages in the several sections being alternately on opposite sides of the purifier.

2. The combination with a sewer, drain or other pipe containing noxious gases, of a vent and purifier comprising a plural number of sections or chambers resting one upon the other—each section having an internal shelf and a vent-passage, the said vent-passages in the several sections being alternately on opposite sides of the purifier.

3. The combination of a plural number of sections or chambers each section or chamber having a flange to make a union with the next section or chamber on which it is superimposed; an internal shelf in each section or chamber having at one side a vent-passage; the upper section or chamber provided in its side walls with vent-openings, and a cap closing the top of said upper section or chamber.

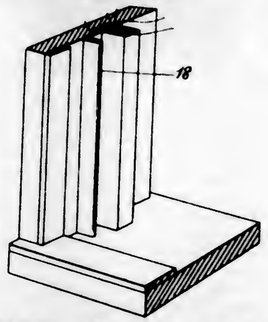
4. The combination with a sewer, drain or other pipe containing noxious gases, of a vent-passage from said sewer, drain or pipe; a base-frame having three flanges one of which enters the said vent-passage; and a vent-purifier comprising a plural number of sections resting one upon the other and the lowermost one resting on one of said base-flanges and receiving within its end the other flange; and an internal shelf in each section and a vent-passage at one side thereof.

810,734. **THEATRICAL APPLIANCE.** BERNARD J. FAGAN, New York, N. Y. Filed Aug. 9, 1905. Serial No. 273,411.

Claim.—1. In a theatrical appliance, a delusion device consisting of a movable shell made of rigid material and having a constricted portion near the center thereof, the internal dimensions of such constricted portion being such that the device is adapted to slip over the shoulders and rest on the hips of the operator and the device being of such dimensions as to completely conceal the operator when in a kneeling position and to expose the legs of the operator when standing, substantially as described.

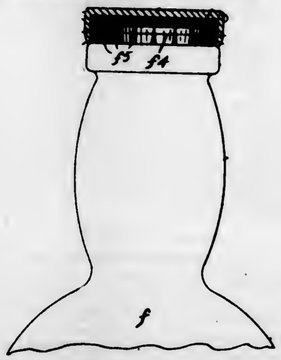
2. In a theatrical appliance, a delusion device consisting of a movable shell made of rigid material comprising two members of frusto-conical form, with their small ends together, thereby forming a constricted portion, the internal dimensions of such constricted portion being such that the device is adapted to slip over the shoulders and rest on the hips of the operator and having a top with a dome-shaped center to receive the head of the operator, the parts being so proportioned as to entirely conceal the operator when kneeling down and expose the legs of the operator when standing, and an illuminating device thereon, substantially as described.

810,735. **WINDOW ATTACHMENT.** CHARLES H. FAULKNER, Somerville, Mass., assignor to Champion Metal Weather Strip and Parting Bead Company, Boston, Mass., a Corporation of Massachusetts. Filed July 17, 1905. Serial No. 270,157.



Claim.—A window-casing attachment composed of a sheet-metal strip bent to form a central or base portion adapted to bear on the face of the casing and having holes for attaching devices, and a three-sided casing at one edge of said base adapted to inclose the exposed portions of a parting-bead, one side of said casing being extended across the plane of the base to enter the casing with the parting-bead, and a folded portion or rib at the opposite side of the base, adapted to enter a groove in the edge of a sash.

810,736. **CLOSURE DEVICE FOR GLASS JARS AND OTHER VESSELS.** WILLIAM B. PENN, Sheepshead Bay, N. Y. Filed Dec. 23, 1904. Serial No. 238,662.



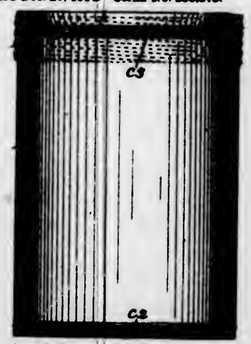
Claim.—1. A bottle or similar vessel having a top neck portion which is provided on the outer surface thereof with teeth or projections and inwardly and downwardly inclined, and a closure device comprising an inner cap having a depending flange or rim and composed of compressible material saturated with preservative material, and an outer cap having a corresponding depending flange or rim and in which the inner cap is placed, the flange or rim of the inner cap and the flange or rim of the outer cap being provided on or in their adjacent faces with projecting teeth the adjacent walls of which are curved or segmental in form in horizontal section, substantially as shown and described.

2. A bottle or other vessel provided with a neck having an annular enlargement near the top thereof, the outer walls of the top portion of said neck being inwardly and downwardly inclined, and a closure device comprising an inner and an outer cap each of which is provided with a depending flange or rim, the inner cap being composed of flexible material saturated with preservative material, and the flanges or rims of both of said caps being provided in or on their adjacent walls with projecting teeth the corresponding walls of which are curved or segmental in form in horizontal section, substantially as shown and described.

3. A bottle or other vessel provided with a neck having an annular enlargement near the top thereof, the outer walls of the top portion of said neck being inwardly and downwardly inclined, and a closure device comprising an inner and an outer cap each of which is provided with a depending flange or rim, the inner cap being composed of flexible material saturated with preservative material, and the flanges or rims of both of said caps being provided in or on their adjacent walls with projecting teeth the corresponding walls of which are curved or segmental in form in horizontal section, the bottom of the flange or rim of the outer cap being also inwardly contracted, substantially as shown and described.

4. A bottle or other vessel provided with a neck having an annular enlargement near the top thereof, the outer walls of the top portion of said neck being inwardly and downwardly inclined, and a closure device comprising an inner and an outer cap each of which is provided with a depending flange or rim, the inner cap being composed of flexible material saturated with preservative material, and the flanges or rims of both of said caps being provided in or on their adjacent walls with projecting teeth the corresponding walls of which are curved or segmental in form in horizontal section, the bottom of the flange or rim of the outer cap being also inwardly contracted, and the top portion of the neck which is inclosed by the closure device being provided with projecting teeth, substantially as shown and described

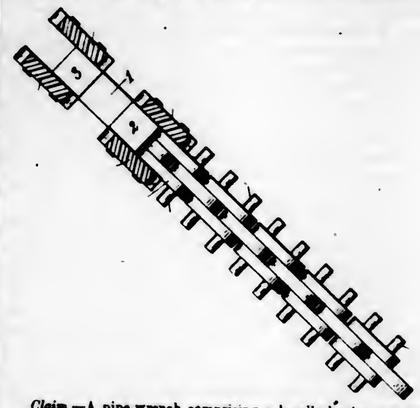
810,737. **METALLIC CAN.** WILLIAM B. PENN, Sheepshead Bay, N. Y. Filed Dec. 27, 1904. Serial No. 238,373.



Claim.—1. A metallic can one end of which is open, the closed end and body of the can being provided with a lining of fibrous material saturated with a preservative material, and a cap or cover for the open end of said can, said cap or cover being provided with a countersunk central portion whereby an inwardly-directed annular wall is formed around said countersunk portion, said cap or cover being also provided with a lining of fibrous material having an upwardly-directed annular rim portion which covers said wall and which bears on the top portion of the lining of the body of the can when the cap is in position, and said cap being also provided with a flange or rim which is threaded to correspond with a similar thread on the open end of the can, substantially as shown and described.

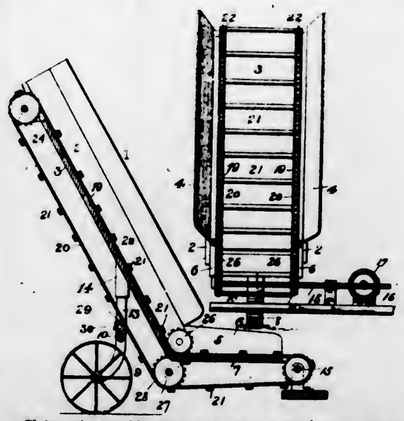
2. A metallic can one end of which is open, the closed end of the can and the body portion of the can being provided with linings of fibrous material saturated with a preservative material and the adjacent or contacting parts of which are beveled, and a cap or cover for the open end of the can, the central portion of which is countersunk so as to form an annular wall, said cap or cover being also provided with a lining of fibrous material saturated with a preservative material and provided with an annular flange or rim which covers said wall, the lining of the body of the can and the lining of the cap or cover where they meet being also beveled, and means for securing the cap or cover in position, substantially as shown and described.

810,738. **PIPE-WRENCH.** STEPHEN A. FESLER, Cupertino, Cal. Filed Sept. 1, 1905. Serial No. 276,763.



Claim.—A pipe-wrench comprising a handle having a forked end, gripping-plates pivoted to the respective members of the fork, each plate having a concaved serrated gripping-surface adapted to grip the pipe, and, beyond said gripping-surface or remote from the pivot thereof, a portion adapted to rest upon the surface of the pipe when the gripping-surface of the opposite plate grips the plate, substantially as described.

810,739. **CORN-FODDER ELEVATOR AND LOADER.** FRANK A. R. FIEBACH, HENRY C. FIEBACH, and OTTO L. FIEBACH, London, Wis. Filed June 23, 1905. Serial No. 266,479.



Claim.—A portable elevator of the character described comprising an inclined upwardly-projecting frame 1, a horizontally-disposed frame 5 pivotally connected to the lower end of said inclined frame, said horizontal frame being adapted to be secured to the frame of a corn-binder, a supporting-frame 9, 13, 14 secured to the lower side of said inclined frame, a caster-wheel pivotally mounted in said supporting-frame, a drive-shaft journaled in the binder-frame adjacent to the end of the horizontal elevator-frame, sprocket-wheels fixed on said shaft, a shaft journaled in the upper end of said inclined frame, sprocket-wheels fixed on said shaft, an endless conveyer arranged on said elevator-frames and driven by the sprocket-wheels on said drive-shaft, and means to guide said conveyer over said frames, substantially as described.

810,740. MAKING HARD-RUBBER BALLS. HARVEY B. FRENCH, Mineral City, Ohio. Filed Apr. 26, 1905. Serial No. 257,396.

Claim.—1. The process of making a hard-rubber ball consisting in masticating two parts india-rubber and hot-milling therewith two parts coal-flour, one part sulfur-flour and three parts talc-powder, then molding and vulcanizing under high pressure a core-ball of this composition and then molding on the core-ball as a center and vulcanizing under low pressure a large ball of the same composition, less the talc.

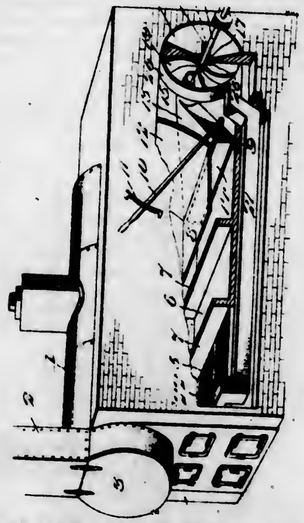
2. The process of making a hard-rubber ball consisting in mixing india-rubber with coal-flour, sulfur-flour and talc-powder, and molding and vulcanizing under high pressure a core-ball of this composition, then molding on the core-ball as a center and vulcanizing under low pressure a larger ball of the same composition, less the talc.

3. The process of making a hard-rubber ball consisting in mixing india-rubber with coal-flour, sulfur-flour and talc-powder and molding and vulcanizing under high pressure a core-ball of this composition, and then molding on the core-ball as a center a larger ball of india-rubber composition.

4. The process of making a hard-rubber ball consisting in molding and vulcanizing under high pressure a core-ball of india-rubber composition, and then molding on the core-ball as a center and vulcanizing under low pressure a larger ball of a composition made by mixing india-rubber with coal-flour, and sulfur-flour.

5. The process of making a hard-rubber ball consisting in molding and vulcanizing under high pressure, a core-ball of india-rubber composition, and then molding on the core-ball as a center and vulcanizing under low pressure a larger ball of similar composition.

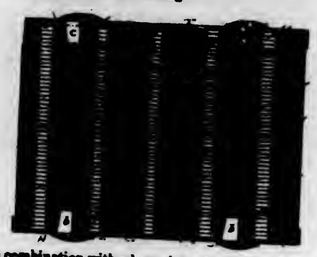
810,741. SMOKE-CONSUMER. WALTER T. FLING and JOHN B. FLINGS, Holt, Mo. Filed May 18, 1905. Serial No. 261,010.



Claim.—In a device of the class described, a furnace provided with a combustion-chamber, a fan-casing, a duct connecting the latter and chamber for communication, one wall of the furnace being provided with a recess terminating in an opening leading through said wall to the casing, a smoke-collecting ball arranged in the furnace and having communication with the casing, a fan in the latter operable for drawing smoke from the member to the casing and forcing it through the duct to the combustion-chamber, a fan-operating shaft extended through the opening in the furnace-wall, and a cut-off valve for regulating the size of said opening.

810,742. BOX FOR HOLDING COINS. ROBERT H. FORSYTH, Washington, D. C. Filed July 28, 1905. Serial No. 271,069.

Claim.—1. In combination with a box or receptacle adapted to hold a plurality of stacks of coins, a lid therefor, a fastening device for the lid adapted to extend in the space between the coin stacks, and means cooperating with the sides of the coin stacks for preventing the fastening device from turning.



2. In combination with a box adapted to hold stacks or columns of coins, a lid therefor, a fastening device for securing the lid in place, said fastening device adapted to extend in the space between the stacks of coin. and a head on said fastening device adapted to fit in said space.

3. In combination with a box adapted to hold stacks of coins, a removable lid therefor, a fastening-bolt extending in the space between the stacks of coins, and a head on the bolt formed with a shank fitting in the space between the coin stacks.

4. In combination with a box adapted to hold a plurality of stacks of coins and having in its ends, openings in line with the space tween the coin stacks, a fastening-bolt extending in said space, and heads on the ends of the bolt formed with shanks extending through the openings in the ends of the box and fitting in the space between the coin stacks.

5. In combination with a box adapted to hold a plurality of stacks of coins, a removable lid therefor, the said lid and bottom of the box being formed each with an opening in line with the space between the coin stacks, a bolt adapted to extend in said space, a head on one end of the same formed with a squared shank extending through the opening in the bottom of the box, fitting in the space between the coin stacks and bearing against the outer side of the bottom, a removable head on the opposite end of the bolt, formed with a squared shank extending through the opening in the lid and fitting in the space between the coin stacks, and a nut applied to the end of the bolt and serving to hold the parts together.

J. In combination with a coin-box adapted to hold a plurality of stacks of coins, a removable lid therefor, a fastening-bolt adapted to extend in the space between the coin stacks, and a removable sealing-head for the bolt formed with an undercut cavity to receive a sealing medium, and having an opening through its bottom to receive the end of the bolt, said parts coöperating with the lid and serving to retain the same in place.

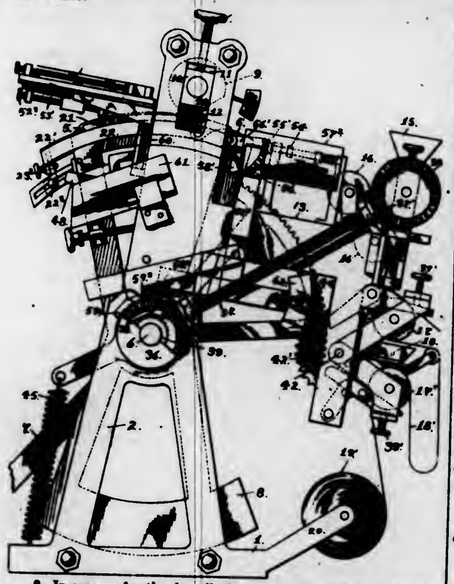
7. In combination with a coin-box adapted to hold a plurality of stacks of coins, a removable lid therefor, a fastening-bolt extending in the space between the coin stacks and having its end threaded, a removable head adapted to be slipped over the threaded end of the bolt and formed with an angular shank fitting the space between the coin stacks, said head having a cavity to receive a sealing medium, and a fastening-nut screwed on the threaded end of the bolt within the cavity in the head.

8. In combination with a coin-box adapted to hold a plurality of stacks of coins, a removable lid therefor, a fastening-bolt extending in the space between the coin stacks, having one end threaded and having fixed to its opposite end a head formed with an angular shank fitting in the angular space between the coin stacks at one end, a removable head adapted to be slipped over the threaded end of the bolt and formed with an angular shank fitting the space between the coin stacks, said head having a cavity to receive a sealing medium, and a fastening-nut screwed on the threaded end of the bolt and situated in the cavity in the head.

9. In combination with a box adapted to hold a plurality of stacks of coins, and formed in its top and bottom with openings in line with the space between the coin stacks, a division-plate fitting within the box and dividing the coin stacks and formed with openings in line with the space between the coin stacks.

810,748. PRINTING APPARATUS. GEORGE H. GIBSON, San Francisco, Cal. Filed Apr. 3, 1905. Serial No. 253,462.

Claim.—1. In a press for the described purpose, the combination with the frame thereof, of a plate-carrier mounted to reck or oscillate within the same, of means carried thereby for clamping an engraved plate to the said carrier, an impression-roller held within the frame above the plate-carrier, of inking means arranged at the forward end of the press, of wiping-rollers and cleaning device located below the inking means, of devices for actuating the inking means on the forward stroke of the plate-carrier to ink the surface of the plate carried thereby and for operating the wiping-rollers and cleaning device to remove the surplus ink therefrom and polish the surface of the plate, of means for returning the plate-carrier to its normal position after the polishing of the surface of the inked plate, a card-feeder for supplying cards to be printed, means carried by the plate-carrier for actuating the card-feeder and the impression-roller on the return forward stroke thereof, and devices for operating said means to coact respectively with the card-feed mechanism and the impression-roller.



2. In a press for the described purpose, the combination with the main frame thereof, of an oscillatory plate-carrier mounted to swing therein, of clamping means carried thereby for holding an engraved plate thereto, of devices for inking, wiping and polishing the surface of the held plate on the forward stroke of the oscillatory plate-carrier, and means carried by the said carrier for actuating the inking, wiping and polishing devices on the forward movement of the said plate-carrier.

3. In a press for the described purpose, the combination with the main frame, of an impression-roller mounted therein, a rack-gear secured to the impression-roller, of an oscillatory plate-carrier working within the main frame, means carried thereby for the clamping of an engraved plate thereto, a vertically-movable rack-plate carried by the plate-carrier, and devices for moving the same in and out of mesh with the gear of the impression-roller.

4. In a press for the described purpose, the combination with the main frame of an oscillatory plate-carrier arranged to swing within the said frame, an impression-roller mounted in the main frame above the plate-carrier, of card-feeding mechanism, a vertically-movable slide-plate carried by the plate-carrier for actuating the card-feeding mechanism, and devices for raising and lowering said slide-plate to place the same into and out of engagement with the said card-feeding mechanism.

5. In a press for the described purpose, the combination with the main frame thereof, of the oscillatory plate-carrier, of means for clamping an engraved plate thereto, of the ink-supplying rolls for inking the surface of the held plate, devices carried by the plate-carrier for actuating said rolls to ink the surface of the held plate on the forward stroke of the plate-carrier, and means for adjusting the pressure of said inking-rolls.

6. The combination with the oscillatory plate-carrier, of means for clamping an engraved plate thereto, of inking-rolls for applying ink to the surface of the held plate on the forward stroke of the plate-carrier, and an adjustable slide carried by the plate-carrier for actuating the said ink-applying rolls on the forward stroke of the plate-carrier.

7. In a press for the described purpose, the combination with the oscillatory plate-carrier, of the wiping-rolls for removing the surplus ink applied to the surface of an engraved plate held to the plate-carrier and polishing the surface of said plate, of devices carried by the plate-carrier for forcing the wiping-rolls toward the held plate on the forward stroke of the plate-carrier, a web of paper working over the wiping-rolls and advanced by the frictional engagement of the said rolls therewith, and means for imparting rotation to the inking-rolls.

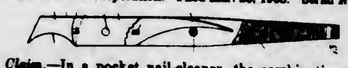
8. In a press for the described purpose, the combination with an oscillatory plate-carrier, of means for clamping an engraved plate thereto, a web of paper for removing the surplus ink applied to the surface of the held plate, of devices for forcing the paper onto the surface of the inked plate during the forward stroke of the carrier-plate, and means for advancing the web of paper over the surface of the plate.

9. In a press for the described purpose, the combination with an oscillatory plate-carrier, of means for clamping an engraved plate thereto, a web of paper for removing the surplus ink applied to the surface of the held plate and polishing the surface thereof, of rolls for forcing the web of paper against the surface of the plate, mechanism for rotating the rolls for advancing the web by frictional contact, and means for moistening the surface of the held plate with a suitable cleaning compound.

10. In a press for the described purpose, the combination with an oscillatory plate-carrier, of the wiping-rolls, a web of paper, working over the face thereof, of devices for throwing the rolls toward the surface of the inked plate to place the paper thereon during the movement of the carrier-plate, of mechanism for actuating the rolls to impart travel to the web of paper.

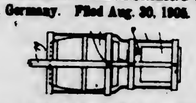
11. In a press for the described purpose, the combination with the main frame, of the impression-roller mounted therein, of an oscillatory plate-carrier working within the main frame, card-feed mechanism for delivering cards to be printed, devices carried by the plate-carrier for actuating the card-feed mechanism and imparting rotation to the impression-roller, a swinging receiver for the printed cards, and means for operating said swinging receiver to deliver the printed cards onto a suitable holder.

810,744. POCKET FINGER-NAIL CLEANER. WILLIAM F. GILBERT, Derby, Conn., assignor of one-half to The H. C. Cook Co., Ansonia, Conn., a Corporation. Filed Mar. 25, 1905. Serial No. 251,963.



Claim.—In a pocket nail-cleaner, the combination with two frame-plates one of which is struck up to form a locking-rib, of a flat plate-like blade pivotally mounted between the outer ends of the said plates and having one of its ends formed with a beak-like scraper having its outer edge beveled and its inner edge cut away to form a semicircular notch, and the said blade being formed at points on opposite sides of its center with notches which receive the said rib, whereby the blade is held with either end turned outward.

810,745. METHOD OF PASTEURIZING BEER. HUGO GRONWALD, Berlin, Germany. Filed Aug. 30, 1905. Serial No. 276,436.

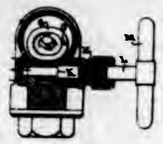


Claim.—1. An improved method of pasteurizing beer in the barrel in which it is to be transported, which consists in dividing the quantity of beer required to fill the barrel between the barrel and a receiver below the same and communicating with it through pipe connections, after having freed said vessels from air by means of carbonic acid, so that the receiver is filled completely and an empty space equal to its contents is left in the barrel in order that the carbonic acid disengaged from the beer in the barrel and receiver during the pasteurizing may collect in the barrel and after cooling be returned to the beer without loss by shaking or other known means, whereupon the pasteurizing apparatus is placed on the floor with the barrel at the bottom so that the receiver can empty itself into the barrel and the excess of carbonic acid mount into the receiver.

2. The method of pasteurizing beer consisting in filling a barrel with beer and a receiver with carbonic acid, connecting said barrel

and receiver by means of a single coupling, then transferring the carbonic acid and a portion of the beer from the receiver into the barrel, then pasteurizing the beer and then retransferring the carbonic acid and beer respectively to the barrel and the receiver.

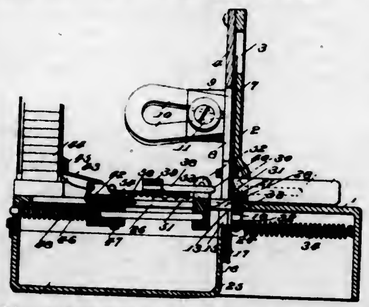
810,746. CHECK-VALVE FOR WATER-GAGES. BENJAMIN HADLEY and BRYAN MOYLAN, Elmira, N. Y. Filed June 17, 1905. Serial No. 265,704.



Claim.—1. The combination, with a water-gage, of a check-valve hinged at one side of its seat, and an adjustable hinge-pin therefor having a screw-threaded stem and a shoulder adapted to engage one side of the valve-knuckle, said stem having the screw-thread thereon cut in a direction whereby, when setting the shoulder against the knuckle, the stem will turn in the same direction as the valve turns when moving to open position.

2. The combination, with a water-gage, of a check-valve supported on an arm hinged at one side of the valve-seat, and a hinge-pin therefor having a shoulder at one side of the arm-knuckle and a screw-threaded stem operated by a handle outside the valve-casing.

810,747. COIN-CONTROLLED VENDING-MACHINE. FRED B. HALL, Brookline, and ALEXANDER MACLEOD, Brighton, Mass., assignors to United States Vending Corporation, Boston, Mass., a Corporation of Maine. Filed Oct. 6, 1904. Serial No. 227,488.



Claim.—1. In a coin-controlled machine, in combination, a forwardly-movable coin-support comprising opposite horizontally-disposed pivoted members notched at their inner ends, and between which ends a coin is designed to rest in a vertical position, said members being constructed and arranged to swing forward at their free ends together with a coin supported thereby, said free ends being gradually moved apart, a fixed support for said members, an actuating member for engaging a coin supported by the latter, and an ejector member against a part whereof a coin is designed to be held by said actuating member as it is freed from the hinged members at or near the limit of the forward movement of the latter.

2. In a coin-controlled machine, in combination, a forwardly-movable coin-support comprising opposite horizontally-disposed laterally-movable pivoted members between the free ends of which a coin is designed to rest in a vertical position, said members being constructed and arranged to swing forward at their free ends with a coin supported thereby, said free ends being gradually moved apart, a fixed support for said members, an actuating member having a flat wall for engaging a coin supported by said members, and an ejecting member having a rod in line with the center of coin and against which the latter is designed to be forced as it is about to be freed from said laterally-movable members at or near the limit of the forward movement of the latter.

3. In a coin-controlled machine, in combination, a coin-support comprising opposite horizontally-disposed laterally-movable pivoted members between the free ends of which a coin vertically disposed is designed to rest, said members being constructed and arranged to swing forward at their free ends with a coin supported thereby, said free ends being gradually moved apart, a fixed support for said members, an actuating member comprising a frame having a wall formed with an opening, and an ejecting member having a rod coincident with said opening and against which a coin is designed to be forced by said wall as a coin is about to be freed from said laterally-movable members at or near the limit of the forward movement of the latter.

4. In a coin-controlled machine, in combination, a coin-support comprising oppositely-disposed laterally-movable members having inner opposite V ends wherein a coin is designed to rest, a fixed support for said members, an actuating member comprising a frame having a depending ear formed with an opening, said ear being normally forward of the coin-support, and movable between the members thereof, and an ejecting member having a rod coincident with said opening and against which the coin is designed to be forced by said ear as it is about to be freed from its support upon the actuating member being pushed inwardly.

5. In a coin-controlled machine, in combination, a fixed plate having an opening formed with parallel edges, an actuating member comprising a frame movable in said opening, a coin-support fixed to the under side of said plate at the forward end of said opening, a portion of said frame being designed to intersect the coin-support, an ejecting member having a block also movable in said opening, a rod carried by said block extended forwardly on a plane above the coin-support and in line with that portion of said frame movable in a plane intersecting the coin-support for forcing the coin from the latter against said rod.

6. In a coin-controlled machine, in combination with an actuating member, a coin-support comprising oppositely-disposed horizontally-movable levers fulcrumed at their outer ends and having inner V-shaped ends, a fixed support therefor, said levers being capable of being swung forward on their vertical pivots when said actuating member is forced inwardly, and springs for returning said levers to their normal positions.

7. In a coin-controlled machine, in combination with an actuating member, a coin-support comprising opposite horizontally-disposed levers having inner opposite V-shaped ends, and a pin mounted in one of the levers intersecting the space between such ends for increasing or diminishing the same, said levers being constructed and arranged to swing forward with a coin supported thereby, the V-shaped ends of said levers being gradually moved apart.

8. In a coin-controlled machine, in combination, a coin-support, an actuating member movable on a plane above said support and having a bore or opening, and a cord-cutting rod in line with said opening notched at its forward end for cutting a cord from which a coin is suspended said rod entering said bore or opening.

9. In a coin-controlled machine, in combination, a coin-support, an actuating member movable on a plane above said support, a plunger for said actuating member having a central bore, and a cord-cutting rod in line with said bore having its forward end notched for severing a cord forced thereby into said bore.

10. In a coin-controlled machine, in combination, a coin-support, an actuating member movable on a plane above said support and having a bore or opening, a cord-cutting rod in line with said opening notched at its forward end, and a stationary plate having a central notch in line with the notch of said rod.

11. In a coin-controlled machine, in combination, an actuating member carrying a spring-held two-way pawl, an ejecting member, a stationary rack with which said pawl is designed to engage, and a shield normally covering such rack to prevent the pawl engaging therewith.

12. In a coin-controlled machine, in combination, an actuating member carrying a spring-held two-way pawl, an ejecting member, a stationary rack with which said pawl is designed to engage, a shield normally covering said rack to prevent the pawl engaging therewith, and means for automatically shifting such shield so as to permit the pawl to engage with the rack when the ejecting member is moved by the actuating member.

13. The combination with the actuating member carrying a spring-held two-way pawl, and a stationary rack with which such pawl is designed to engage, of the ejecting member, the shield carried thereby normally covering such rack, a spring for holding such shield over the rack, and means for forcing the shield away from the rack when the ejecting member is moved by the actuating member.

14. The combination with the actuating member carrying a spring-held two-way pawl, and a stationary rack with which such pawl is designed to engage, of the ejecting member, the shield carried thereby normally covering such rack, a spring for holding such shield over the rack, said shield having a beveled wall, and a stationary pin with which said wall is designed to engage for forcing the shield away from the rack when the ejecting member is moved by the actuating member.

15. In a coin-controlled machine, in combination, with an actuating member, a coin-support comprising oppositely-disposed levers having inner spaced-apart notched ends, and a pin inserted transversely through the notched end of one of the levers, intersecting the inner end of the notch, and itself having a notch coincident with that of the lever.

16. In a coin-controlled machine having a horizontally-disposed plate a depending wall in advance of the cash-drawer, a coin-support beneath said plate, actuating and ejecting mechanism movable on the plate and having a plunger designed to move above said support when pushed inwardly, and a coin passage-way through which said plunger extends, and a return-opening to one side of the plunger, whereby a coin deposited in the passage-way when the plunger is pushed inwardly will be deflected through the return-opening.

17. In a coin-controlled machine, in combination, a coin-support, an actuating member comprising an open-top frame having forward and rearward walls formed with coincident openings, a coin or washer when on said support being located between said walls in line with said openings, an ejecting member having a rod normally projecting into the opening of the rearward wall, such ejecting member being operated by the engagement of a coin with said rod, the said rearward wall of said frame serving to remove washers from such rod upon the release of pressure on the actuating member.

810,748. CONCRETE BUILDING-BLOCK. WINFIELD A. HALLER, New Orleans La., and JAMES W. BILLINGSLEY, Tivoli, N. Y., assignors to Edwin H. Sanderson, Brooklyn, N. Y., Henry Hobart Porter, Lawrence, N. Y., Francis Blossom, Brooklyn, N. Y., and Richmond Talbot, Tuxedo, N. Y. Filed Feb. 21, 1905. Serial No. 246,703.

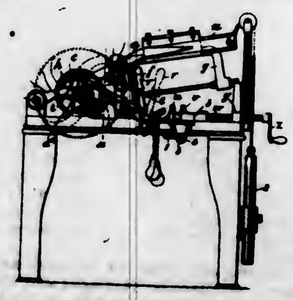
Claim.—1. The building-block having a body provided with an alining groove extending around the same and provided with a plurality of supporting-shelves projecting from one face of said block, said shelves having an upturned outer edge and being reinforced by a metallic reinforce embedded in said block, each of said shelves being provided with ribs to form a plurality of supporting-grooves in its upper face.

2. The building-block formed of reinforced concrete comprising a body formed with an alining groove and with supporting-shelves having pockets formed integral with said block and extending outward from one face of the same.

3. The building-block formed of reinforced concrete comprising a body provided with supporting-shelves having pockets formed integral with said body and extending outward from the face of the same.

4. The building-block comprising a body, provided with supporting-shelves having pockets formed integral with said body and extending outward from the face of the same.

810,749. HACKSAWING-MACHINE. JOSEPH HAMPTON, Sr., King's Hill, Wednesbury, England. Filed Nov. 10, 1904. Serial No. 232,230.



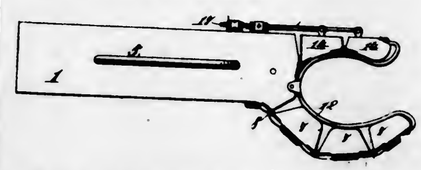
Claim.—1. In a hacksaw-machine, the combination with the machine-table, a driving-shaft, a saw-frame-carrying lever provided with a slot through which the driving-shaft extends, said slot permitting the lever to work over the said shaft, and an upright carried by the table and provided with an independent axis for said lever, said axis being situated at the rear of the driving-shaft.

2. In a hacksaw-machine, the combination with the table of the machine, of an operating-shaft, a saw-frame-carrying lever, a saw-frame thereon operated from a crank-plate on said shaft, a belt or driving pulley on the said shaft, a starting and stopping lever pivoted at one side of the table of the machine and in front of the belt-pulley, a bell-crank lever having the boss thereof mounted on said shaft between the belt-pulley and the frame of the machine and a connecting-rod between the starting and stopping lever and one arm of said bell-crank lever, said boss having a projection adapted to engage in a notch in the frame when the machine is at rest.

3. In a hacksaw-machine, an operating-shaft, a bell-crank lever carried thereby, a hacksaw-frame-carrying lever, a stop mechanism, and a stop-lever having one of its arms projecting in the path of the hacksaw-frame-carrying lever and the other of its arms terminating under one of the arms of the bell-crank lever and actuating in connection with said hacksaw-frame-carrying lever and said bell-crank lever said stop mechanism.

4. In a hacksaw-machine, an operating-shaft, a bell-crank lever carried thereon, a hacksaw-frame-carrying lever, a stop mechanism, and a stop-lever having one of its arms projecting in the path of the hacksaw-frame-carrying lever and the other of its arms provided with an adjustable seat situated under one of the arms of the bell-crank lever, said stop-lever in connection with said hacksaw-frame-carrying lever and said bell-crank lever actuating said stop mechanism.

810,750. MILKING DEVICE. LEWIS G. HARPER, Westchester, Pa. Filed May 27, 1905. Serial No. 262,677.



Claim.—1. A milking device having a series of contractible and relaxing fingers composed of jointed sections.

2. A milking device having a plurality of contractible and relaxing fingers, and means for operating said fingers inclosed within the latter.

3. A milking device having a plurality of contractible and relaxing fingers, and a finger having a fixed adjustable position and coöperating therewith.

4. A milking device having a plurality of fingers simulating the fingers of the human hand and composed of jointed sections, the finger representing the thumb being held in opposing or resisting position to the remaining fingers, which have a contracting and relaxing movement imparted thereto.

5. A milking device having a plurality of fingers made up of jointed sections, spring devices coöperating with said sections to relax the same and restore them to normal position, and means connected to the fingers for contracting them against resistance of the spring devices.

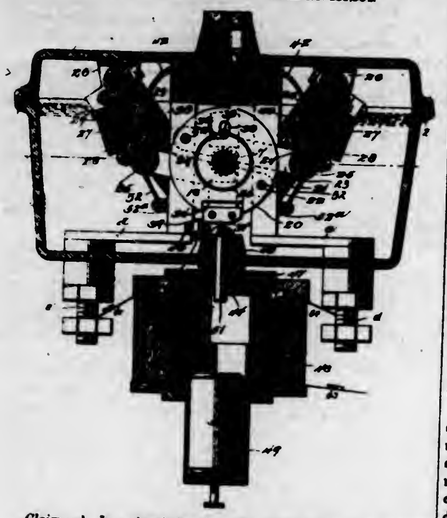
6. A milking device having a plurality of fingers made up of jointed sections provided with spring means for restoring them to normal position when relaxed, a resistance means coöperating with the first-named fingers, and means for contracting the latter fingers.

7. A milking device having a plurality of fingers provided with means for restoring them to normal position, tapes connected to the fingers for contracting the same, means for drawing the tapes to contract the fingers, and a resistance-finger coöperating with the contractible fingers and having a fixed adjusted position.

8. In a milking device, a plurality of contractible and expansible fingers, a resistance-finger coöperating therewith and arranged in opposition thereto, contracting-tapes attached to the fingers, and a crank-shaft having a series of cranks to which the tapes are secured.

9. A milking device having a plurality of contractible and expansible fingers, and a single resistance-finger having adjusting means connected thereto.

810,731. ELECTRIC-CIRCUIT BREAKER. FRANK O. HARTMAN, Mansfield, Ohio. Filed Apr. 6, 1903. Serial No. 151,304.



Claim.—1. In a circuit-breaker, the combination with an operating-shaft, of a plurality of switches movable simultaneously into normal position by the operating-shaft, a loose and a fast disk carried by the shaft, one of the disks connected with the switches, the other of said disks adapted to operate the first-named disk, a single locking device for retaining the switches in normal position, and an electroresponsive device for effecting the simultaneous release of the switches.

2. In a circuit-breaker, the combination with a plurality of switches, of an inner disk, a handle-rod to which the disk is secured, the switches movable simultaneously into normal position by means of the inner disk and handle-rod, and an outer disk connected by means of swinging arms to the movable portions of the switches, an operating-handle, a single locking device for holding said switches in normal position, an electroresponsive device operating the instant the movable contacts are brought into engagement with the terminal blocks, while an overload condition exists in the circuit, and effecting under such circumstances the simultaneous release of said switches independent of any restraining influence on the operating-handle.

3. An automatic circuit-breaker comprising a case adapted to hold an insulating fluid, a plurality of electric switches contained within the case, the switches consisting of movable and stationary contacts, an operating-shaft, a disk secured to the shaft, an annulus loosely mounted on the disk, links connecting the annulus with each of the movable contacts, means for retaining the movable contacts in normal position and an electroresponsive device effecting the release of the movable contacts upon the occurrence of an overload in the circuit.

4. An automatic circuit-breaker comprising a casing, a plurality of switches within the casing, a single operating-shaft controlling the movement of the switches in one direction, means for releasably retaining the switches in normal position and an electroresponsive device for releasing the switches, the electroresponsive device comprising a yoke, a solenoid supported thereby and provided with an aperture, a tube located in the aperture in the solenoid, a collar-pin receivable in an aperture formed in the casing adjacent the switch-retaining means, a core operating in the tube, the core adapted to engage the collar-pin to move the latter into engagement with the switch-retaining means to release the switches.

5. An automatic circuit-breaker comprising a plurality of stationary terminal blocks, swinging laminated contacts adapted to removably engage the terminal blocks, an inner disk, an annular disk rotatably mounted on the inner disk, means connecting the contacts and the annular disk, means for simultaneously drawing the contacts into engagement with the terminal blocks, means for locking the contacts in such position, and an electroresponsive device for effecting the simultaneous release of the contacts, and their operation independently of the inner disk.

6. An automatic circuit-breaker comprising suitably supported and insulated terminal blocks, movable contacts, swinging arms to which the contacts are secured, lugs in which the arms are journaled, tension means constantly engaging the arms to yieldingly retain the contacts away from the blocks, a means freely rotatable in either direction to which the arms are connected, a manually-operated rotatable means, locking means for retaining the two rotatable means together when the contacts are in engagement with the blocks and electroresponsive means adapted to engage the locking means to effect the release of the freely-rotating means irrespective of the operation of the manually-operated means.

7. An automatic circuit-breaker composed of a case consisting of upper and lower portions adapted to hold an insulating fluid, terminal blocks, insulating material, to which the terminal blocks are secured, the insulating material fastened to the upper portion of the case, laminated movable contacts for engaging said terminal blocks, suitably-supported swinging arms to which the movable contacts are attached, flat springs mounted between the swinging arms and adapted to exert pressure against the same to throw the contacts away from the terminal blocks when the switches are unlocked, means for drawing said movable contacts simultaneously into normal position, means for locking said contacts in such position, and an electroresponsive device operating directly on the locking device and effecting the simultaneous release of the movable contacts upon the occurrence of an overload condition in the circuit.

8. In a circuit-breaker, the combination of a plurality of switches adapted to be connected in series on one side of an electrical circuit, means of operating said switches, a single locking device for holding said switches in normal position, an operating-handle having an inner and outer disk fitted thereon and connected to arms carrying contacts through the medium of suitable links, an electroresponsive device operating under overload conditions to effect the release of said switches independently of any restraining influence in the operating-handle.

9. An electric switch composed of a case consisting of an upper and a lower portion, and adapted to hold an insulating fluid, insulating material fastened to the upper part of the case, terminal blocks secured to the insulating material, laminated movable contacts for engaging said terminal blocks, swinging arms by which the movable contacts are carried, flat springs mounted between the swinging arms and adapted to exert pressure against the same to throw the contacts away from the terminal blocks when the switches are unlocked, an operating-handle, means for drawing said movable contacts simultaneously into engagement with said contact-blocks, means for locking or restraining the movable contacts in such position, means for unlocking or effecting the simultaneous release of said movable contacts and permitting their unrestrained movement by turning the controlling-handle in the direction opposite to that taken in closing the switches.

10. An automatic circuit-breaker comprising a suitably-supported rotatable shaft, tension means for normally retaining the shaft at and returning it to one limit of its rotary movement, a disk secured to the shaft, an annular disk rotatably supported on the first disk, suitably-supported swinging arms, links connecting the annular disk and the arms, contact-carrying members secured to and insulated from the arms, contacts carried by the members, terminal blocks adapted to be engaged by the contacts, means for normally forcing the contacts away from the blocks, releasable locking means for retaining the contacts in engagement with the blocks, and an electroresponsive device for actuating the locking device to effect the release of the contacts.

11. In an automatic electric circuit-breaker, a case adapted to inclose the mechanism thereof and retain an insulating liquid, an operating-bar, a handle secured to the projecting end of the bar, an inner disk secured to the operating-bar, an outer disk fitted to rotate on the inner disk, a catch fitted to the sides of the disks, the disks provided with pinways adapted to register with each other, a pin receivable in the pinways and adapted to releasably secure the disks together, means for locking the outer disk against rotation, and means for engaging the locking means and releasing the outer disk.

12. In an automatic electric circuit-breaker, a case, an operating-rod journaled in bearings in the case, one end of the rod projecting outside of the case, a handle secured to the rod, a disk secured to the operating-rod, an outer disk fitted to rotate on the first-named disk, links connected to the outer disk, a catch fitted to said disks, swinging arms, springs adapted to exert a pressure against the swinging arms to break the circuit when the catch is released manually or automatically.

13. A circuit-breaker comprising an operating-shaft, disks mounted thereon, suitably-supported swinging arms, links connecting one of the disks and the swinging arms, carrying members secured to the arms, contacts carried by the members, terminal blocks engaged by the contacts, means tending to force the contacts away from the blocks, a catch carried by one of the disks, a stop against which the catch abuts to retain the contacts in engagement with the blocks, a releasing-pin located adjacent the stop and an electroresponsive device adapted to impinge against the releasing-pin, to cause the latter to release the catch from the stop.

14. In a circuit-breaker, the combination with an operating-shaft, and a plurality of separated terminals, of a plurality of bridge-contacts movable simultaneously into and out of normal position, to connect or disconnect the terminals, a disk secured to the operating-shaft, a second disk loosely mounted on the fast disk, means connecting the loose disk and the movable bridge-contacts, means for releasably locking the two disks together when rotated in one direction only, means tending to move the switches and loose disk in the opposite direction, and an electroresponsive device for releasing the locking means to permit the simultaneous movement of the contacts independent of the operating-shaft, the loose disk rotating freely upon the fast disk when rotated in such opposite direction.

15. A circuit-breaker comprising a casing, an operating-shaft journaled in the casing, one end of the shaft projecting outside the casing, a handle secured to the protruding end of the shaft, a spring secured to the shaft and adapted to return the latter to one limit of its rotary movement, a disk secured to the shaft, an annulus rotatably mounted on the disk, suitably-supported swinging bars, contacts carried by the bars, links connecting the annulus and bars, terminal blocks with which the contacts are adapted to engage to close the circuit and means for automatically breaking the circuit.

16. An automatic circuit-breaker comprising stationary isolated terminals, movable bridge-contacts, a rotatable disk, an annulus loosely mounted on the disk, and located intermediate the bridge-contacts, means secured to the bridge-contacts and to approximately opposite points on the annulus, means for locking the annulus and disk when rotation is given the disk in one direction, and electroresponsive mechanism for releasing the locking means to permit a movement of the annulus irrespective of the disk.

17. A circuit-breaker comprising a suitable casing, stationary terminal blocks located therein, and insulated therefrom, connectors secured to the terminal blocks, binding-posts in contact with the connectors, swinging contacts adapted to engage the terminal blocks, a rotary annulus, means pivotally connecting the swinging contacts and annulus, a disk upon which the annulus is mounted and rotates, a catch located between the annulus and disk, means connected with the disk for causing the operation of the catch, gravity-operated means for locking the annulus when the contacts are in engagement with the terminal blocks and electroresponsive means connected with the binding-posts to release the gravity-operating locking means.

18. A circuit-breaker comprising a plurality of terminal blocks, contacts movable toward and from the blocks, a suitably-supported rotary shaft, a disk fast on the shaft, an outer disk loosely supported on the fast disk, means connecting the contacts and outer disk, a locking means receivable between the disks and adapted to frictionally engage the disks when the shaft is rotated in one direction to cause the rotation of the outer disk, a stop engaged by the locking means to normally prevent the reverse rotation of the disks and means for releasing the engagement of the locking means and the stop.

19. A circuit-breaker comprising terminal blocks, suitably-supported swinging contacts adapted to engage the blocks, a rotatable rod, a disk mounted thereon, an annulus rotatably supported on the disk, means connecting the annulus and swinging contacts, locking means located between the disk and annulus, whereby the rotation of the disk in one direction will carry the annulus with it, means for automatically locking the annulus when the contacts are in engagement with the terminals and an electroresponsive means engaging the locking means and releasing the contacts.

20. In a circuit-breaker, the combination with stationary terminals, and contacts movable toward and from the terminals, of a rotary shaft, a recessed member mounted thereon and rotating therewith, an annular member loosely supported upon the rotary member, a locking means carried by the annular member, means connecting the annular member and the movable contacts, a tension means connected with the shaft to retain the latter at one limit of its rotary movement, the locking means adapted to frictionally engage and connect the members when the shaft is rotated against the strength of the tension means, the locking means partly received in the recessed member when the contacts engage the terminals, means for retaining the locking means in the recessed member, and electroresponsive means adapted to release the locking means.

21. A circuit-breaker comprising a plurality of stationary isolated and insulated terminals, an electroresponsive device in circuit with the terminals, movable contacts adapted to engage and connect the terminals, a suitably-supported rotatable disk, an annulus mounted on the disk and having a movement independent thereof, means for locking the disk and annulus together when the disk is rotated in one direction, the annulus connected with and controlling the movement of the contacts, means for locking the annulus in normal position, and means actuated by the electroresponsive device for automatically releasing the annulus.

22. In a circuit-breaker, the combination with stationary terminals, an electroresponsive device in circuit therewith and movable contacts adapted to connect the terminals and complete the circuit, of a rotating annulus with which the contacts are connected, a second rotatable member on which the annulus is supported, the annulus and rotatable member provided with adjacent grooves, a catch-pin received in the grooves and locking the rotatable member and annulus when the rotatable member is rotated in one direction, locking means for retaining the annulus in normal position, and means actuated by the electroresponsive device to release the locking means and permit the annulus to rotate freely on the rotatable member.

23. The combination in a circuit-breaker with a series of independent stationary terminals, an electroresponsive device in circuit therewith and movable contacts adapted to engage the terminals and close the circuit, of a rotatable means with which the contacts are connected, a sliding member carried by the rotatable means, a movable catch against which the sliding member is adapted to abut, and means actuated by the electroresponsive device adapted to engage and actuate the sliding member to release the rotatable means.

24. In a circuit-breaker, the combination with a plurality of terminals, an electroresponsive device in circuit therewith and movable contacts adapted to engage the terminals and complete the circuit, of a rotatable means with which the contacts are connected, a sliding member carried by the rotatable means and normally extending therebeyond, an abutment with which the sliding member engages to retain the rotatable means in set position, a disk upon which the rotatable means is supported, the disk and rotatable means provided with registering recesses, a pin carried by the sliding member and received in the recesses to lock the disk and rotatable means together and means actuated by the electroresponive device for simultaneously releasing the disk and rotatable means and the rotatable means and abutment.

25. The combination in a circuit-breaker, with a plurality of terminals, and contacts movable toward and from the terminals, of a rotatable disk, an annulus supported upon and rotating independently of the disk, means connecting the annulus and contacts, means for locking the disk and annulus together, a sliding member carried by the annulus, a foot on the sliding member, the toe of the foot being beveled, a pin over which the foot rides, and behind which it lies to retain the annulus in set position and means for releasing the sliding member.

26. The combination with a series of terminals, and movable contacts, of a rotatable disk having an inclined groove formed in the periphery thereof, an annulus received upon and rotating independently of the disk, the annulus provided with a recess in communication with the groove, means connecting the annulus and contacts, a sliding member carried by the annulus, a foot on the member, a pin carried by the member and received in the groove and recess to lock the disk and annulus together, means engaged by the foot to retain the annulus in set position and means for engaging the foot to simultaneously release the annulus from engagement with the disk and with the foot-retaining means.

27. The combination in a circuit-breaker, with stationary terminals and movable contacts, of a rotatable shaft, a disk secured thereupon, an annulus supported upon and rotating independently of the disk, means connecting the annulus and contacts, the annulus provided with a recess formed in the bore thereof, the disk provided with a peripheral inclined groove in communication with the recess, a sliding member embracing the disk and annulus, the sliding member being cut away to receive the shaft, a pin carried by the sliding member and receivable in the recess and groove, means engaged by the sliding member for retaining the annulus in set position, and means engaging the sliding member for releasing it from the retaining means and permitting it to rotate freely on the disk.

28. The combination with a plurality of terminals and movable contacts engaging the terminals, of a suitably-supported rotatable member connected with the contacts and having a slot formed therein, a sliding member carried by the rotatable member, a foot on the sliding member receivable in the slot in the rotatable member and normally partially protruding therefrom, means engaged by the foot

for retaining the rotatable member in set position and means for releasing the sliding member.

29. The combination with a plurality of terminals and contacts movable toward and from the terminals, of a rotatable means connected with the contacts, a sliding member, resilient means connecting the sliding member with the rotatable means, the sliding member normally extending beyond the rotatable means, means for engaging the sliding member to retain the rotatable means in set position and means for releasing the sliding member.

30. The combination with a plurality of terminals and movable contacts adapted to engage the terminals, of a rotatable means connected with the contacts, a sliding member carried by the rotatable means, a spring-pressed pin over which the sliding member rides and by which it is held and means for releasing the sliding member.

31. The combination in a circuit-breaker, with a plurality of terminals, of insulated blocks, to which the terminals are secured, a casing, means securing the insulated blocks to the casing, suitably-supported swinging bars, arms secured to and insulated from the swinging bars, contacts carried by the arms and engaging the terminals, a rotatably-supported member, links pivotally connecting the swinging bars and the rotatable member, means for manually rotating the member in one direction, means for automatically retaining the member at one limit of its movement and means operating to release the rotatable member to permit its free rotation in the opposite direction.

32. The combination in a circuit-breaker, with a plurality of terminals, of a suitably-supported recessed swinging arm, an insulated sleeve received in the recess, a carrying-arm received in the insulated sleeve, means for securing the sleeve to the swinging arm, contacts secured to the carrying-arm, means for drawing the contacts into engagement with the terminals, means for retaining the contacts in such position and means for releasing the contacts.

33. In a circuit-breaker, the combination with stationary terminals, and contacts movable toward and from the terminals, a suitably-journaled shaft, a handle thereon, means carried by the shaft and connected with the contacts for actuating the latter, means automatically tending to force the contacts away from the terminals, and resilient means independent of the automatic means, the resilient means secured to the shaft for returning it to one limit of its movement independently of the movement of the contacts.

34. In a circuit-breaker, the combination with terminals and contacts adapted to removably engage the terminals, of a shaft, a disk secured thereon, a rotatable member connected with the disk, means connecting the rotatable member and the contacts, means for locking the disk and rotatable member together when the shaft is turned in one direction, means for retaining the rotatable member at one limit of its movement, means for automatically releasing the rotatable member and means for limiting the rotary movement of the shaft.

35. The combination in a circuit-breaker with terminals and contacts movable toward and from the terminals, of a suitably-journaled shaft, means mounted on the shaft and connected with the contacts for actuating the latter, means tending to rotate the shaft in one direction, a pin projecting transversely of the shaft, and a projection on one of the journals of the shaft against which the pin impinges to limit the rotary movement of the shaft.

36. An automatic circuit-breaker comprising suitably-supported and insulated terminal blocks, suitably-supported contacts movable toward and from the blocks, yielding means constantly tending to force and retain the contacts away from the blocks, a means freely-rotatable in either direction with which freely-rotatable means the contacts are connected, a second rotatable means on which the freely-rotatable means is supported, locking means for retaining the two rotatable means together for bringing the contacts into engagement with the terminals and for holding the contacts in such position and electroresponsive means adapted to engage the locking means and release the rotating means from each other irrespective of the operation of the supporting rotary means.

810,752. SPOUT FOR COLLECTING CRUDE TURPENTINE. JAMES I. HATFIELD, Douglas, Ga., assignor of one-half to Joshua H. Dent, Douglas, Ga. Filed Nov. 10, 1905. Serial No. 286,766.

Claim.—As an improved article of manufacture, a seamless sheet-metal spout for gathering turpentine, comprising a body portion having a curved upper edge from which extends a concave portion, the curved edge and concaved portion being adapted to lie against the surface of a tree, a part which projects from the lower part of the concave portion, and raised sides which converge from the upper edge downward, and perforations through the upper portion of the plate, substantially as shown.

810,753. SPIKE-PROTECTOR FOR SHOE-SPIKES. WALLACE O. HATFIELD, Syracuse, N. Y., assignor of one-third to Tobias C. Griffin. Filed Apr. 13, 1905. Serial No. 255,175.

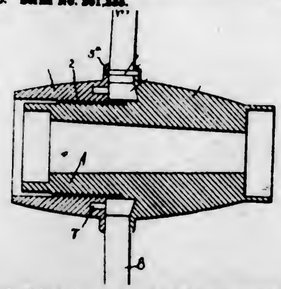
Claim.—1. In combination with the heel and toe spikes of a shoe, heel and toe pads having recesses receiving said spikes, an elastic strap connecting said pads, said pads being recessed to receive said strap and means for positively securing the ends of said strap in said pads.

2. In a protector for spike-shoes having heel and toe spikes, the combination of separate heel and toe pads applied to the spikes and frictionally held thereby, an elastic strap connecting said pads in a plane above their lower surfaces, said pads being formed with longitudinal kerfs to receive the ends of said strap, and a securing element positively uniting the ends of said strap to said pads and extending through the kerfed sections of said pad and said strap held therebetween.

3. A protector for spiked shoes embodying elastic heel and toe pads interfitting over the heel and toe spikes of said shoes and held thereupon by frictional resistance, and an elastic strap connecting said pads and increasing said frictional resistance with said heel and toe pads by its tension.

4. A protector for spiked shoes embodying elastic heel and toe pads interfitting over the heel and toe spikes of said shoes, said pads being suitably recessed to receive said spikes and being held upon said spikes solely by frictional resistance, and an elastic connecting-strap positively secured to each of said pads and increasing said frictional resistance of said pads with said spikes by its tension.

810,754. HUB. JOHN C. HAWKINS, Loudonville, Ohio. Filed May 19, 1905. Serial No. 261,233.

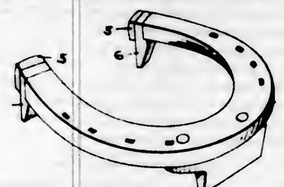


Claim.—1. A hub comprising an internally-threaded member, a second member of substantially the same diameter provided with an externally-threaded cylindrical portion adapted to enter and engage said internally-threaded member, tapering spacers, dowel-pins carried by said spacers, said pins entering recesses formed in the internally-threaded member, said spacers being adapted to form sockets for the spokes and means for securing said members into an engaging position.

2. A hub comprising an internally-threaded member having an annular flange, an externally-threaded member also provided with an annular flange, tapering spacers having dowel-pins projecting therefrom, said pins entering recesses formed in the internally-threaded member, said spacers forming sockets for the spokes and bolts which pass through the annular flanges of both the externally-threaded and the internally-threaded members to bind said members into position.

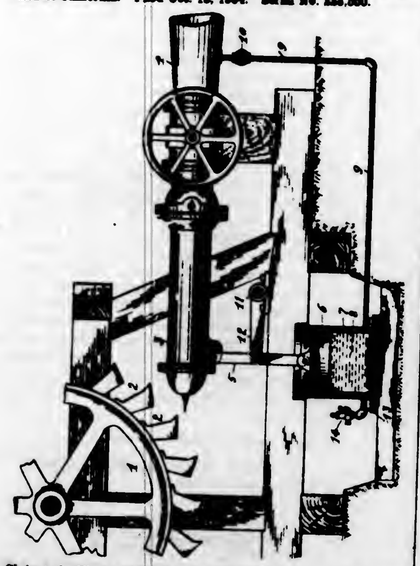
810,755. HORSESHOE-CALK. NELS WEBB, Harmony, Minn. Filed June 15, 1905. Serial No. 265,204.

Claim.—1. The combination, with a horseshoe provided on its heel with a threaded extension, of a calk having a socket to receive said extension, and a lock-nut for said extension, substantially as described.



2. The combination, with a horseshoe having its heel terminating in a squared shank, of a calk having a wedge-shaped wearing-surface and a socket to receive said shank, said calk having a recess on one side forming a shoulder and a bearing-surface for the heel of the shoe, and means for securing said calk on said shank.

810,756. HYDRAULIC SUPPORT FOR DEFLECTING NOZZLES. GROSVEN J. HENRY, Jr., San Francisco, Cal., assignor of one-half to The Pelton Water Wheel Company, San Francisco, Cal., a Corporation of California. Filed Oct. 15, 1904. Serial No. 228,560.



Claim.—1. The combination with a deflectable nozzle for water-wheels, of hydraulic means for supporting the said nozzle when at rest, and mechanism for controlling the position of the nozzle

2. The combination with a deflectable nozzle for water-wheels, of a cylinder, a piston working therein, a liquid-support within the cylinder for the piston, of connection between the piston and the nozzle, a rock-shaft, and means for imparting the movement of the rock-shaft to the nozzle in order to adjust the position thereof.

3. The combination with a deflectable nozzle, of a main or line pipe to which the same is pivoted, a pressure-cylinder, of connection between the said cylinder and the main or line pipe, a piston working within the cylinder, connection between the piston and the nozzle, and means for imparting movement to the said nozzle so as to place the stream discharged therefrom in whole or in part onto the buckets of a water-wheel.

4. The combination with a deflectable nozzle, of a main or line pipe to which the same is pivoted, a pressure-cylinder, of means for admitting fluid under pressure thereto, a piston working within the said cylinder, connection between the piston and the nozzle, and means for moving the nozzle so as to direct the stream discharged therefrom in whole or in part onto the buckets of a water-wheel.

5. The combination with a deflectable nozzle, of a main or line pipe to which the same is pivoted, a pressure-cylinder, of connection between said cylinder and the main or line pipe for admitting fluid thereto under pressure, a piston working within the cylinder, a valved outlet for the said cylinder, connection between the piston and the nozzle, and means for adjusting the position of the nozzle so as to direct the stream discharged therefrom in whole or in part onto the buckets of a water-wheel.

6. The combination with a water-wheel, of a main-line supply-pipe, a deflectable device located at the outer end of the supply-pipe for changing the position of the jet issuing therefrom, of hydraulic means for balancing said device, and mechanism for controlling the position of the deflectable device.

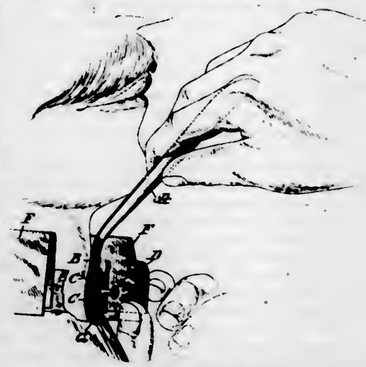
7. The combination with a water-wheel, of a main-line supply-pipe, a deflectable device located at the end of the supply-pipe for changing the position of the jet issuing therefrom, and fluid-actuated means for balancing said deflectable device.

8. The combination with a water-wheel, of a main-line supply-pipe, a deflectable nozzle pivoted to the outer end of the supply-pipe, said nozzle being rigid throughout its length, mechanism for varying the position of said nozzle to direct the jet issuing therefrom onto or off the buckets of the water-wheel, and fluid-actuated means for balancing the said nozzle.

810,757. RAIL-JOINT. JOSEPH B. HENSLEY, Beeville, Tex. Filed Feb. 25, 1905. Serial No. 247,268.

Claim.—In a rail-joint, a pair of rails assembled in endwise relation, a splicing member having a longitudinal channel to receive the meeting ends of the rails; said channel being of an inner cross-sectional contour conforming to that of the rails, and presenting a base-plate and a pair of side plates formed integral therewith, one of said side plates being of a thickness equaling the width of the adjacent overhanging portion of the rail-head and the other side plate of a relatively increased thickness throughout its entire surface area and having at its upper edge an upwardly-projecting and longitudinally-extending portion or flange designed to bear upon the adjacent side face of the rail-head, the side and base plates being designed to contact throughout their entire inner surface area with the corresponding faces of the rails.

810,758. BUTTON-HOLDER. AUSTIN M. HILL, Rockville Center, N. Y. Filed Feb. 1, 1905. Serial No. 243,695.

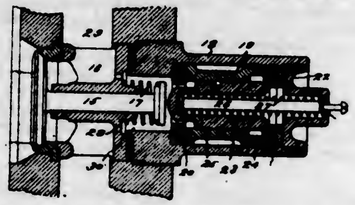


Claim.—1. As a new article of manufacture a holder for collar-buttons, consisting of a handle, a reduced shank, an approximately flat disk-shaped head on the shank and having in its front face a shallow circular recess with a central depression for receiving the base or back of a collar-button, and a reaming-lug on the peripheral edge of the disk opposite the handle, the handle standing at an angle to the shank, being inclined in direction of the recessed face of the head, whereby provision is made for inserting the shank and head between the throat of the wearer and the shirt-band so as to engage

the back or base of the collar-button with the recess of the head to hold the same and thereby facilitate the buttoning of the collar to the collar-button, as set forth.

2. As a new article of manufacture a holder for collar-buttons, comprising an approximately flat disk-shaped head having a shallow circular recess in its front face with a central depression for receiving the base or back of a collar-button and provided with a reaming-lug projecting from its peripheral edge, and a handle inclined in direction of the recessed face of the head, as set forth.

810,759. VALVE FOR COMPOUND AIR-COMPRESSORS. BENJAMIN HILL, Norwalk, Conn. Filed Jan. 24, 1905. Serial No. 242,496.



Claim.—1. A valve for the intake-passage of an air-compressor having a valve-disk adapted to open and close the passage, a plunger movable toward and from the disk, said plunger having a surface at its inner end that is exposed to the air-pressure in the intake-passage when the plunger is at its inner limit, and a larger surface back from its inner end that is exposed to the air-pressure in the intake-passage when the plunger is moved from its inner limit, whereby the pressure against the smaller surface will tend to move the plunger away from the disk and pressure against the larger surface will tend to hold the plunger away from the disk, and a spring arranged to force the plunger against the air-pressure when the pressure drops below normal and cause the plunger to interfere with the ordinary action of the disk, substantially as specified.

2. A valve for an air-compressor having an inwardly-opening valve-disk, a spring tending to draw the disk to its seat, a plunger movable toward and from the disk, said plunger having surfaces with areas of different extent arranged to be subject to the air-pressure on the intake side of the disk, the smaller surface only being subject to the air-pressure when the plunger is at its inner limit and both the smaller and larger surfaces being subject to the air-pressure when the plunger is back from its inner limit, and a spring arranged to force the plunger against the air-pressure when the pressure drops below normal and cause the plunger to interfere with the ordinary action of the disk, substantially as specified.

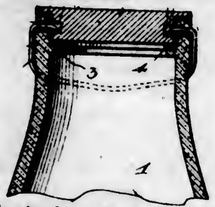
3. A valve for an air-compressor having a valve-disk, a plunger movable toward and from the disk and having surfaces with areas of different extent arranged to be subject to the air-pressure on the intake side of the disk, a seat at the inner limit of movement of the plunger against which the inner end of the plunger seats and leaves only the smaller surfaces exposed to the air-pressure when the plunger is at its inner limit, a seat at the outer limit of movement of the plunger against which the outer end of the plunger seats so that the air-pressure will be exerted against the smaller and the larger surfaces of the plunger when the plunger is at its outer limit, and a spring arranged to force the plunger against the air-pressure when the pressure drops below normal and cause the plunger to interfere with the ordinary action of the disk, substantially as specified.

4. A valve for an air-compressor having a valve-disk, a plunger movable toward and from the disk, said plunger having a seating edge at its inner end that is less in diameter than the diameter of the body of the plunger, and a seating-flange at its outer end that is greater in diameter than the diameter of the body of the plunger, a seat against which the inner edge seats when the plunger is at its inner limit, a seat against which the outer flange seats when the plunger is at its outer limit, and a spring arranged to thrust the plunger against the air-pressure when the pressure drops below normal and cause the plunger to interfere with the ordinary action of the disk, substantially as specified.

5. A valve for an air-compressor having a valve-disk, a spring tending to draw the disk to its seat, a case, a sleeve in the case, a seat at each end of the sleeve, a plunger movable in the sleeve toward and from the seats and subject to the air-pressure on the intake side of the disk, said plunger having a seating edge at its inner end and a larger seating-flange at its outer end, and a spring tending to thrust the plunger against the air-pressure toward the disk and cause an interference with the ordinary action of the disk, substantially as specified.

6. A valve for an air-compressor having a valve-disk, a spring tending to draw the disk to its seat, a case, a sleeve in the case, a packing at each end of the sleeve, a nut holding the sleeve and packings in position, a plunger movable in the sleeve toward and from the packings, said plunger being subject to the air-pressure on the intake side of the disk and having a reduced seating edge at its inner end adapted to seat against the inner packing and an enlarged seating-flange at its outer end adapted to seat against the outer packing, and a spring tending to thrust the plunger against the air-pressure toward the disk, substantially as specified.

810,760. JAR-CLOSURE. EDGAR C. HILL, Columbus, Ohio. Filed Sept. 28, 1905. Serial No. 280,603.



Claim.—1. In a jar-closure, the combination with the neck of a jar having formed therein oppositely-disposed apertures and an inwardly-projecting annular shoulder, of a cap adapted to fit into said neck and into engagement with the shoulder therein, said cap having oppositely-disposed recesses formed in its sides to aline with the apertures in said neck, an elastic washer arranged between said cap and shoulder, a bail-shaped locking device having right-angularly-bent locking-fingers formed on its ends to engage the alined apertures and recesses in said neck and cap, to clamp said cap into tight engagement with said washer and shoulder, substantially as described.

2. In a jar-closure, the combination with the neck of a jar having formed therein oppositely-disposed apertures and an inwardly-projecting annular shoulder, of a flanged cap having formed therein oppositely-disposed recesses, said cap being adapted to fit within said neck and to engage said shoulder, a bail-shaped locking device having right-angularly-bent locking-fingers formed on its ends to engage the alined slots and recesses in said cap and neck, laterally-bent cam projections formed on the ends of said fingers whereby when said bail is turned downwardly said laterally-bent ends will engage the lower walls of the recesses in said cap and force the latter downwardly into engagement with the washer and shoulder of the jar, substantially as described.

810,761. GUN-SIGHT. LUCIAN HILLABRANDT, Johnstown, N. Y. Filed Dec. 6, 1904. Serial No. 235,622.

Claim.—1. A gun-sight, comprising a ring-shaped member, having a threaded projection, a nut on the said projection and provided with a plurality of openings, and a sight held within the ring-shaped member.

2. In a gun-sight, the combination with the breech-bolt, of a ring-shaped member provided with a projection, an adjustable member on the projection and engaging the breech-bolt, a sight within the ring-shaped member, and a spring exerting downward tension on the said ring-shaped member.

3. The combination with a gun having a vertical opening, of a sight comprising a ring-shaped member having a threaded projection extending into the opening of the gun, a nut on the threaded projection of the ring-shaped member, means for locking the nut in position, and a sight held within the ring-shaped member.

4. In a gun-sight, the combination with the breech-bolt of a gun, of a sight provided with a projection, means on the projection and engaging the breech-bolt for adjusting the said sight, and means for locking the adjusting means in position.

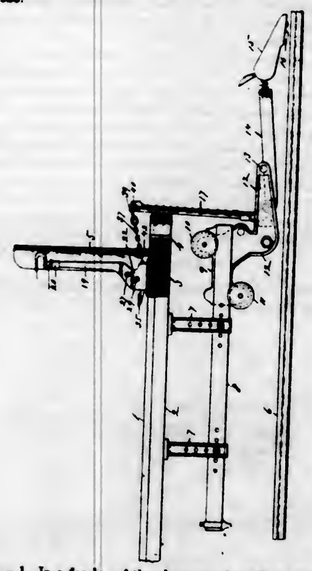
5. In a gun-sight, the combination with the breech-bolt of a gun provided with an opening, of a sight provided with a threaded projection entering the opening of the breech-bolt, a nut on the threaded projection and engaging the breech-bolt, and a spring secured to the breech-bolt and to the sight.

6. In a gun-sight, the combination with the breech-bolt of a gun having an opening therein and provided with a lug, of a ring-like sight having a threaded projection entering the opening of the breech-bolt, a nut on the threaded projection and provided with a plurality of openings for receiving the lug of the breech-bolt, and a spring secured to the sight and to the breech-bolt.

7. In a gun-sight, the combination with the breech-bolt of a gun provided with an opening, and a lug adjacent to said opening, of a sight in the form of a ring-like body and having a threaded projection entering the opening of the breech-bolt, an auxiliary sight removably held in the body, a nut on the threaded projection and provided with a plurality of openings, and a spring having one end secured to the breech-bolt and its other end to the main sight.

8. A gun-sight, comprising a main sight in the form of a ring-like body and having an annular rib on its inner face, and an auxiliary disk sight having an opening therein, said disk sight being made thin and adapted to be sprung into place in the main sight.

810,762. FENDER FOR CARS AND OTHER VEHICLES. GEORGE HITWOOD, Laconia, N. H. Filed June 24, 1905. Serial No. 266,830.



Claim.—1. In a fender of the character described, pulleys supported on the platform of the car; a chain extending over said pulleys to the bumper-guard and connected thereto; a pedal within reach of the foot of the motorman; means intermediate of the pedal and chain whereby the chain is held at any desired point by releasing the pedal; and a lifting-rod connected with the chain and within reach of the motorman, whereby the chain may be lifted, released, held at any point or dropped entirely, for the purpose set forth.

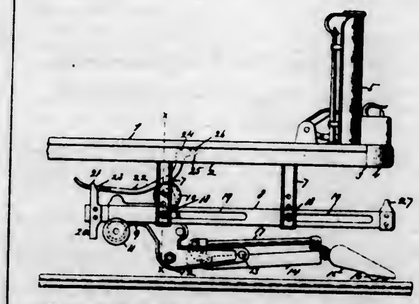
2. In a fender of the character described, a standard supported on the platform of the car; a lifting-rod slidingly supported in the standard and provided with a handle adapted to rest on the upper end of said standard; a pair of grooved pulleys disposed one above the other in the standard, one of said pulleys being provided with sprockets on the inner faces of its flanges; a chain extending from the lifting-rod over the pulleys and into engagement with said sprockets and with its opposite end secured to the bumper-guard, and means for retaining the sprocketed pulley at any point and releasing the same, for the purpose set forth.

3. In a fender of the character described, a standard supported on the platform of the car; a lifting-rod slidingly supported in the standard and provided with a handle adapted to rest on the upper end of said standard; a pair of grooved pulleys disposed one above the other in the standard, the lower pulley being provided with sprockets on its inner faces; a ratchet-wheel rigid with the lower pulley; a notched pedal held normally with its notch in engagement with the ratchet; and a chain extending from the lifting-rod over the pulleys and into engagement with the sprockets, and thence to the bumper-guard to which it is connected, for the purpose set forth.

4. In a fender of the character described, a standard supported on the platform of the car; a lifting-rod slidingly supported in the standard and provided with a handle adapted to rest on the upper end of said standard; a pair of grooved pulleys disposed one above the other in the standard, the lower pulley being provided with sprockets on its inner faces; a ratchet-wheel rigid with the lower pulley; a notched pedal held normally with its notch in engagement with the ratchet; and a chain extending from the lifting-rod over the pulleys and into engagement with the sprockets, and thence to the bumper-guard to which it is connected, the lower pulley being set farther from the dashboard than the upper pulley, and the side of the standard next the dashboard being recessed near the lower pulley, for the purpose set forth.

5. In a fender of the character described, a standard supported on the platform of the car; a lifting-rod slidingly supported in the standard and provided with a handle adapted to rest on the upper end of said standard, a pair of grooved pulleys disposed one above the other in the standard, one of said pulleys being provided with sprockets on the inner faces of its flanges; a chain extending from the lifting-rod over the pulleys and into engagement with said sprockets and with its opposite end secured to the bumper-guard; and means for retaining the sprocketed pulley at any point and releasing the same, said standard being vertically channeled on the side facing the dashboard, and the lifting-rod and chain being adapted to slide in the channel, for the purpose set forth.

810,763. FENDER FOR CARS AND OTHER VEHICLES. GEORGE HITWOOD, Laconia, N. H. Filed June 24, 1905. Serial No. 266,831.



Claim.—1. In a fender of the character described, substantially horizontal supporting-rails sustained by and under the car-body and adapted to slide horizontally with relation to the car-body; and a fender sustained by the supporting-rails and adapted to slide horizontally under the car with relation to said rails, whereby the available rearward movement of the fender under and with relation to the car-body comprises the sum of the possible movement of the fender with relation to the supporting-rails and the possible movement of the supporting-rails with relation to the car-body.

2. In a fender of the character described, substantially horizontal supporting-rails sustained by and under the car-body and adapted to slide horizontally with relation to the car-body; a fender sustained by the supporting-rails and adapted to slide horizontally under the car with relation to said rails, whereby the available rearward movement of the fender under and with relation to the car-body comprises the sum of the possible movement of the fender with relation to the supporting-rails and the possible movement of the supporting-rails with relation to the car-body; and mechanism for detachably locking the supporting-rails at the extreme forward ends of their possible movement, for the purpose set forth.

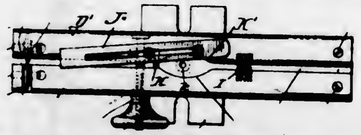
3. In a fender of the character described, hangers secured to and extending from the under side of the car-body; substantially horizontal supporting-rails provided with longitudinal slots 19; means intermediate of the hangers and supporting-rails and extending into said slots, whereby said supporting-rails are slidingly connected with and sustained by the hangers; and a fender sustained by the supporting-rails and adapted to slide horizontally under the car with relation to said rails, whereby the available rearward movement of the fender under and with relation to the car-body comprises the sum of the possible movement of the fender with relation to the sup-

porting-rails and the possible movement of the supporting-rails with relation to the car-body.

4. In a fender of the character described, hangers secured to and extending from the under side of the car-body; substantially horizontal supporting-rails provided with longitudinal slots 19; means intermediate of the hangers and supporting-rails and extending into said slots whereby said supporting-rails are slidingly connected with and sustained by the hangers; mechanism for detachably locking the supporting-rails at the extreme forward ends of their possible movement; and a fender sustained by the supporting-rails and adapted to slide horizontally under the car with relation to said rails, whereby the available rearward movement of the fender under and with relation to the car-body comprises the sum of the possible movement of the fender with relation to the supporting-rails and the possible movement of the supporting-rails with relation to the car-body.

5. In a fender of the character described, hangers secured to and extending from the under side of the car-body; the substantially horizontal supporting-rails 8 provided with longitudinal slots 19 whereby said rails are slidingly connected with and sustained by the hangers; a folding fender supported slidingly by said rails by means of suitable rolls or wheels moving on the rails; projections extending up from the rear portions of the supporting-rails; and swinging arms provided with holes near their outer ends, pivotally supported by the car-body and adapted to extend down over and in the path of the upper wheels or rolls, and to engage with the projections by means of said holes, substantially as and for the purpose set forth.

810,764. PIPE-CUTTER. EDWARD H. HOLLINGSHEAD and CHARLES P. JENNINGS, Bradford, Pa. Filed Apr. 24, 1905. Serial No. 257,206.



Claim.—1. A pipe-cutter comprising a pair of non-rotatable cutter-arms pivoted to a suitable fixed support, cutters mounted on said cutter-arms and means for causing said cutters to approach one to the other, substantially as described.

2. A pipe-cutter comprising two parallel non-rotatable cutter-arms pivoted to a suitable fixed support, rotary cutters mounted on said cutter-arms and means for causing said cutters to approach one to the other, substantially as described.

3. A pipe-cutter comprising a base-plate, cutter-arms secured to said base-plate and parallel thereto, means for securing said base-plate to a fixed support, cutters mounted on said cutter-arms and means for causing said cutters to approach one to the other, substantially as described.

4. A pipe-cutter comprising a stationary base-plate, non-rotatable cutter-arms pivoted to said base-plate, cutters mounted in said cutter-arms and means for causing said cutters to approach one to the other, substantially as described.

5. A pipe-cutter comprising a base-plate having a longitudinal slot in one end thereof, cutter-arms mounted on said base-plate and parallel thereto, cutters carried by said cutter-arms and means for causing said cutters to approach one to the other, substantially as described.

6. A pipe-cutter comprising a base-plate having a segmental slot in one end thereof, cutter-arms mounted on said base-plate, cutters carried by said cutter-arms and means for causing said cutters to approach one to the other, substantially as described.

7. A pipe-cutter comprising a fixed base-plate having a slot therein, cutter-arms pivoted to said base-plate, cutters carried by said cutter-arms and means for causing said cutters to approach one to the other, substantially as described.

8. A pipe-cutter comprising a base-plate having a longitudinal slot in one end thereof, said slot extending diagonally to the perpendicular of said base-plate, cutter-arms, and means for causing said cutters to approach one to the other.

9. A pipe-cutter comprising a base-plate, a pair of cutter-arms located in the same horizontal plane and mounted on said base-plate, cutters carried by said cutter-arms, said cutters having their axes located in a plane different from that of said cutter-arms, and means for causing said cutters to approach one to the other, substantially as described.

10. A pipe-cutter comprising a base-plate, cutter-arms mounted thereon, cutters carried by said cutter-arms, said cutters having their axes located in a plane diagonal to the plane of said cutter-arms, and means for causing said cutters to approach one to the other, substantially as described.

11. A pipe-cutter comprising a base-plate having a slot therein, cutter-arms mounted on said base-plate and parallel thereto, said cutter-arms being separated by a space, said space being in alinement with said slot, cutters carried by said cutter-arms and means for causing said cutters to approach one to the other, substantially as described.

12. In a pipe-cutter, the combination with the base-plate of cutter-arms parallel thereto, each of said arms being pivoted at one end to said base-plate, cutters mounted in the opposite ends of said cutter-arms and means intermediate the ends thereof for causing said cutters to approach one to the other, substantially as described.

13. A pipe-cutter comprising a base-plate, cutter-arms pivoted to said base-plate, cutters carried thereby, a bolt extending through said cutter-arms and adapted to draw the same together, and a hand-operated nut on the outer end of said bolt.

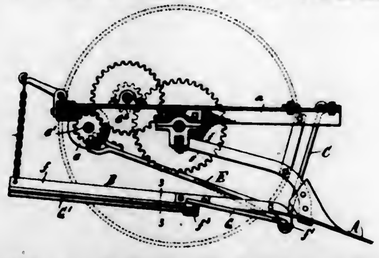
14. In a pipe-cutter, the combination with the cutter-arms and the cutters carried thereby, of a bolt rigidly held in one of said arms and passing loosely through the other and a nut on the outer end of said bolt, substantially as described.

15. In a pipe-cutter, the combination with the base-plate, the cutter-arms and the cutters, of a bolt passing through said cutter-arms and adapted to draw the same together and a spring adapted to force said arms apart, substantially as described.

16. In a pipe-cutter, the combination with the base-plate, the cutter-arms and the cutters, of a bolt passing through said arms, a spring located between said arms and a stop limiting the movement thereof, substantially as described.

17. In a pipe-cutter, the combination with the base-plate, the cutter-arms and the cutters, of means for drawing said arms together and a gage carried by one of said arms, substantially as described.

810,765. POTATO-DIGGER. JACOB JOHNSEN and EDWARD A. PRESCH, Hamburg, N. Y. Filed Dec. 21, 1904. Serial No. 237,789.



Claim.—1. A shaking separator for potato-diggers provided with longitudinal spaced separating-tines arranged in two sets, one in advance of the other, the tines of the front set being arranged nearer together than those of the rear set and having their rear ends elevated above the front ends of the rear tines, substantially as set forth.

2. A shaking separator for potato-diggers comprising a single rigid frame, and longitudinal spaced separating-tines supported by said frame and arranged in two sets, one in advance of the other, the tines of the front set being arranged nearer together than those of the rear set and having their ends elevated above the front ends of the rear tines, substantially as set forth.

3. In a potato-digger, a shaking separator comprising longitudinal spaced separating-tines arranged in two sets, one in advance of the other, the tines of the rear set being spaced farther apart than those of the front set and extending forwardly beneath the rear ends of the front tines, a single rigid frame supporting both sets of separating-tines, and means for shaking said frame, substantially as set forth.

4. The combination of a separator for potato-diggers having longitudinal spaced separating-tines arranged in two sets, one in advance of the other, the tines of the rear set being fixed to said separator, means for vibrating said separator, and means for rocking said front set of tines in addition to their movement with the separator, substantially as set forth.

5. In a potato-digger, the combination of a rigid frame having

a front cross-bar and a cross-bar intermediate of its ends, a set of longitudinal spaced separating-tines secured to and extending rearwardly from each cross-bar, the tines of the front set being spaced nearer together than those of the rear set and having their front ends elevated above the front ends of the rear tines, and means for shaking said separator in a forward and rearward direction, substantially as set forth.

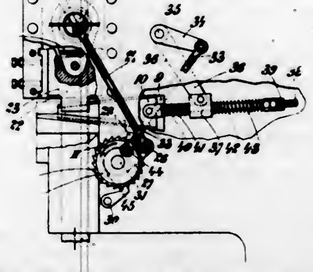
6. The combination of a separator for potato-diggers having longitudinal spaced separating-tines arranged in two sets, one in advance of the other, the tines of said rear set being fixed to said separator and spaced farther apart than the tines of the front set, means for vibrating said separator, and means for rocking said front set of tines in addition to their movement with the separator, substantially as set forth.

7. The combination of a separator-frame, longitudinal spaced separating-tines carried thereby and arranged in two sets, one in advance of the other, the tines of the rear set being fixed to the separator-frame and the tines of the front set being mounted thereon to oscillate vertically, means for vibrating said separator, and means for oscillating said front set of tines, substantially as set forth.

8. The combination of a separator-frame having a fixed bar and a rocking cross-bar adjacent to its front end, longitudinal separating-tines secured to said fixed cross-bar, longitudinal separating-tines secured to said rocking cross-bar, means for vibrating said separator-frame, and means for rocking said front cross-bar, substantially as set forth.

9. The combination of a separator-frame having a fixed cross-bar and a front cross-bar journaled to rock on said frame, longitudinal separating-tines secured to said fixed and rocking cross-bars, swinging supporting-links for said separator-frame fixed to said front cross-bar, and means for vibrating said separator, whereby said front cross-bar is rocked on said frame, substantially as set forth.

810,766. DRIVING MECHANISM. HUGO JOHN, Erfurt, Germany. Filed Jan. 6, 1905. Serial No. 239,999.



Claim.—1. An intermittent driving mechanism for machine-tools, comprising a pair of eccentrics arranged at an angle of one hundred and eighty degrees with respect to each other, slide members for transmitting the movement of the eccentrics to the tool, and a pair of wedges operating at an angle with respect to the direction of the movement of the tool and interposed between the said members and the tool-holder, one of said wedges acting alternately as a lock and the other of said wedges acting alternately as a driving means for the tool.

2. An intermittent driving mechanism for machine-tools, comprising a pair of eccentrics arranged at an angle of one hundred and eighty degrees with respect to each other, slide members for transmitting the movement of the eccentrics to the tool, a pair of wedges operating at an angle with respect to the direction of the movement of the tool and interposed between the said members and the tool-holder, one of said wedges acting alternately as a lock and the other of said wedges acting alternately as a driving means for the tool, and means for operating the wedges.

3. A driving mechanism for machine-tools, comprising a pair of eccentrics arranged at an angle of one hundred and eighty degrees with respect to each other, blocks inclosing said eccentrics, slide members for guiding said blocks and adapted to transmit the movement of the eccentrics to a tool-holder, and a pair of wedges interposed between the members and the tool-holder, moving in a direction at an angle with respect to the direction of the movement of the tool-holder, one of said wedges acting alternately as a lock and the other of said wedges alternately acting as a driving means during the movement of the tool-holder.

4. A driving mechanism for machine-tools, comprising a pair of eccentrics arranged at an angle of one hundred and eighty degrees with respect to each other, blocks inclosing said eccentrics, slide members for guiding said blocks and adapted to transmit the movement of the eccentrics to a tool-holder, a pair of wedges interposed between the members and the tool-holder, moving in a direction at an angle with respect to the direction of the movement of the tool-holder, one of said wedges alternately acting as a lock and the other of said wedges alternately acting as a driving means during the movement of the tool-holder, and means for operating the wedges.

5. An intermittent driving mechanism for machine-tools comprising a pair of wedges moving in a direction at an angle with respect to the direction of movement of a tool-holder, one of said wedges alternately acting as a lock and the other as a driving means for the holder.

6. An intermittent driving mechanism for machine-tools, comprising a pair of wedges moving in a direction at an angle with respect to the direction of movement of a tool-holder, one of said wedges alternately acting as a lock and the other as driving means for the holder, and means for operating said wedges.

7. An intermittent driving mechanism for machine-tools, comprising means for operating a tool-holder, of a pair of wedges operating between said means and tool-holder and moving in a direction at an angle with respect to the direction of the movement of the tool-holder, one of said wedges alternately acting as a lock and the other of said wedges alternately acting as a drive for the tool-holder during the operation thereof.

8. An intermittent driving mechanism for machine-tools, comprising means for operating a tool-holder, of a pair of wedges operating between said means and tool-holder and moving in a direction at an angle with respect to the direction of the movement of the tool-holder, one of said wedges alternately acting as a lock and the other of said wedges alternately acting as a drive for the tool-holder during the operation thereof, and means for operating the said wedges.

9. An intermittent driving mechanism for machine-tools, comprising a pair of eccentrics, driving-blocks inclosing said eccentrics and operated thereby, and slide members for guiding the said blocks.

10. An intermittent driving mechanism for machine-tools comprising a pair of eccentrics arranged at an angle of one hundred and eighty degrees with respect to each other, slide members for transmitting the movement of the eccentrics to the tool, a pair of wedges operating at an angle with respect to the direction of the movement of the tool and interposed between the said members and a tool-holder, one of said wedges alternately acting as a lock and the other of said wedges alternately acting as a driving means for the tool, and compression-springs for moving the wedges.

11. An intermittent driving mechanism for machine-tools, comprising a pair of eccentrics arranged at an angle of one hundred and eighty degrees with respect to each other, slide members for transmitting the movement of the eccentrics to the tool, a pair of wedges operating at an angle with respect to the direction of the movement of the tool and interposed between the said members and the tool-holder, one of said wedges alternately acting as a lock and the other of said wedges alternately acting as a driving means for the tool, compression-springs for moving the wedges, and operating means for the said springs.

12. An intermittent driving mechanism for machine-tools, comprising a pair of wedges moving in a direction at an angle with respect to the direction of movement of a tool-holder, one of said wedges alternately acting as a lock and the other as a driving means for the holder, springs for moving the wedges, and operating means for the springs.

13. An intermittent driving mechanism for machine-tools, comprising a pair of wedges moving at an angle with respect to the direction of the movement of the tool and acting as a lock and drive for the tool.

14. An intermittent driving mechanism for machine-tools, comprising a pair of wedges moving in a direction at an angle with respect to the direction of movement of the tool and one of said wedges alternately acting as a lock and the other of said wedges alternately acting as a drive for the tool.

15. An intermittent driving mechanism for machine-tools, comprising a pair of wedges operating at an angle with respect to the direction of the movement of the tool and each of said wedges alternately acting as a lock and drive for the tool during the intermittent operation thereof.

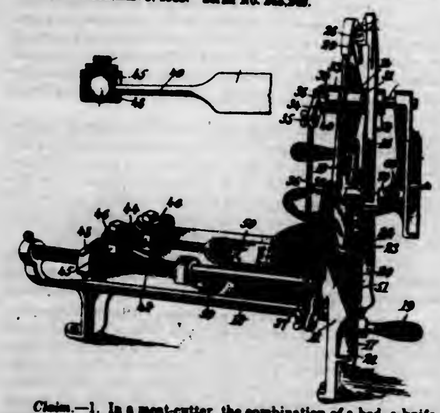
16. An intermittent driving mechanism for machine-tools, com-

prising a pair of wedges moving at an angle with respect to the direction of the movement of the tool and acting as a lock and drive for the tool-holder and adapted to automatically withdraw the tool-holder after it has been moved forward, and a tool-holder associating with the said wedges.

17. An intermittent driving mechanism for machine-tools, comprising a pair of wedges moving in a direction at an angle with respect to the direction of movement of the tool and one of said wedges alternately acting as a lock and the other of said wedges alternately acting as a drive for the tool-holder and adapted to automatically withdraw the tool-holder after it has been moved forward, and a tool-holder associating with the said wedges.

18. An intermittent driving mechanism for machine-tools, comprising a pair of wedges operating at an angle with respect to the direction of the movement of the tool and each of said wedges alternately acting as a lock and drive for the tool-holder during the intermittent operation thereof and adapted to automatically withdraw the tool-holder after it has been moved forward, and a tool-holder associating with the said wedges.

810,767. MEAT-CUTTER. ALFRED W. JOHNSON, New Brunswick, N. J. Filed Mar. 3, 1905. Serial No. 248,249.



Claim.—1. In a meat-cutter, the combination of a bed, a knife-frame pivotally mounted thereon, and guiding devices for said frame, comprising lugs integrally mounted on the inside of the frame, each lug being provided with a groove, and a shoe having a projection entering said groove and adjustably mounted upon each of said lugs.

2. In a meat-cutter, the combination of a bed, a swinging knife-frame, a blade mounted on said knife-frame, said blade having a cutting edge offset toward the bed, means for preventing the blade from coming into contact with the end of the bed, a shaft by which said frame is pivoted on the machine, a guiding device for the frame above the shaft, and a plurality of guiding devices for the frame below the shaft.

3. In a meat-cutter, the combination of a bed, a knife-frame pivotally mounted thereon, a compressible washer between the knife-frame and the stationary part of the bed, guiding devices for the frame mounted on opposite sides of the shaft, said guiding devices comprising a plurality of lugs integrally mounted on the inside of the knife-frame, each lug being provided with a groove, a shoe having a projection entering said groove and adjustably mounted upon each one of said lugs, a roller mounted on each of said shoes, and tracks rigidly mounted with respect to the bed for said rollers.

4. In a meat-cutter the combination of a bed, a swinging knife-frame, a blade mounted on said knife-frame, and means for preventing the cutting edge of the blade from coming into contact with the end of the bed, said means comprising a rib on the bed below the end thereof and adapted to engage with the blade at a point beyond its cutting edge.

5. In a meat-cutter, the combination of a frame, a bed, a swinging knife-frame, a blade mounted on said knife-frame, and means for preventing the cutting edge of the blade from coming into contact with the end of the bed, said means comprising a rib integrally mounted on the frame and projecting beyond the end thereof, said rib being segmental in shape and drawn upon the arc of a circle struck from the pivotal point at which the knife-frame is suspended as a center and below the lowest point of the meat-trough.

6. A cutting-machine having a frame, a bed, a movable cutter and a rib integral with the frame mounted below the end of the bed in position to engage the cutter and keep its edge from the end of the bed, said rib extending beyond the end of the bed.

7. In a meat-cutter, the combination of a bed, a frame upon which said bed is mounted, a shaft mounted on said frame, a knife-frame mounted upon said shaft provided with a blade, means for forcing said knife toward said first-mentioned frame, a compressible washer between the knife-frame and the main frame, a pair of tracks located on the main frame, rollers mounted on the knife-frame and engaging said tracks, and a rib mounted on the main frame and projecting beyond the edge of the bed for engaging with the knife and preventing it from coming into contact with the edge of the bed.

8. In a meat-cutter, the combination of a bed having an extension at the front end thereof, a shaft mounted on said extension at the front end thereof, a knife-frame pivotally mounted by means of said shaft, said shaft having a thread upon it on the inside of said extension, a nut engaging with said thread, a feed-screw, an arm for transmitting motion to the feed-screw, and means for preventing the nut from becoming loosened on the shaft; said means comprising a series of notches on the edge of the nut, and projections connected with said arm and engaging said notches.

9. In a meat-cutter, the combination of a bed having an extension at the front end thereof, a shaft mounted on said extension, a knife-frame pivotally mounted by means of said shaft, said shaft having a thread upon it on the inside of said extension, a nut engaging with said thread, a feed-screw, and means for transmitting motion from said shaft to the feed-screw, said shaft also being provided with a flat side, said means comprising a set-screw engaging said flat side, a series of notches on the edge of the nut, and projections engaging said notches.

10. In a meat-cutter, the combination of a bed, a frame upon which said bed is mounted, a shaft mounted on said frame, a knife-frame pivotally mounted by means of said shaft and provided with a blade, means for forcing said knife toward said first-mentioned frame, a compressible washer between the knife-frame and the main frame, a pair of tracks located on the main frame, rollers mounted on the knife-frame and engaging said tracks, a rib mounted on the main frame and projecting beyond the edge of the bed for engaging with the knife and preventing it from coming into contact with the bed, and a guide for a sharpening implement mounted on the knife-frame, said guide being adjustable to and from the knife-frame.

11. In a meat-cutter, the combination of a bed, a swinging knife-frame, a blade mounted on the knife-frame, said blade having a cutting edge offset toward the bed, a shaft on which said frame is pivoted, guiding devices for the frame mounted on opposite sides of the shaft, and a guide for a sharpening implement mounted on the knife-frame and adjustable toward and from the knife-frame.

12. In a meat-cutter, the combination of a bed, a knife-frame, a blade mounted on said knife-frame, said blade having a cutting edge offset toward the bed, means for preventing the edge of the blade from coming into contact with the end of the bed, and a guide for a sharpening implement adjustably mounted on the knife-frame, said guide comprising two ribs placed at an angle to each other for guiding the sharpening implement, and a stud at the meeting-point of said ribs.

13. In a meat-cutter, the combination of a knife-frame, a blade mounted on said knife-frame, and a guide for a sharpening implement adjustably mounted on the said frame, said guide comprising two ribs placed at an angle to each other for guiding the sharpening implement.

14. In a meat-cutter, the combination of a knife-frame, a blade mounted thereon, and a guide for a sharpening implement carried by the knife-frame and adjustable thereon.

15. In a meat-cutter, the combination of a bed, a frame upon which said bed is mounted, a shaft mounted on said frame, a knife-frame pivotally mounted by means of said shaft and provided with a blade, means for forcing said knife toward said first-mentioned frame, a compressible washer between the knife-frame and the main frame, a pair of tracks located on the main frame, rollers mounted on the knife-frame and engaging said tracks, a rib mounted on the main frame and projecting beyond the edge of the bed for engaging with the end of the knife and preventing its cutting part from coming into contact with the bed, a feed-screw, means for transmitting motion from said shaft to said feed-screw, a cross-head connected with said feed-screw and adapted to travel therealong, and two adjustable claws mounted on said cross-head, one of said claws being longer than the other.

16. In a meat-cutter, the combination of a bed having an extension, a shaft mounted on said extension, a cutter-frame pivotally mounted by means of said shaft, a feed-screw, means for transmitting motion from the shaft to the feed-screw, a nut engaging with said feed-screw, a cross-head upon which said nut is mounted, said cross-head being provided with two cups, a nut adapted to be secured to each cup, said cups being provided with spherical interior surfaces, a ball in each of said cups engaging with said spherical surfaces, and a claw rigidly connected with each of said balls, one of said claws being longer than the other.

17. In a cutting device the combination of a V-shaped bed, rotatable toothed wheels mounted in said bed near the front edge thereof and projecting beyond the inner surface of the bed, means for pressing material against said wheels, and a cutting-blade mounted to move past the edge of said bed; said pressing means comprising a plate pivotally mounted with respect to the bed and having a freely-turning grooved roller mounted on the lower side thereof.

18. In a meat-cutter, the combination of a bed, a knife-frame mounted to swing across the edge of the bed, said bed being provided with a stud, a clamping device comprising a plate, and a freely-rotatable grooved roller mounted below said plate, said clamping device being provided with a series of holes by which it is adapted to be pivotally mounted in any desired position upon said stud.

19. In a meat-cutter, the combination of a bed, a stud thereon, and a clamping device comprising a plate and a freely-rotatable roller mounted below said plate, said clamping device being provided with means for pivotally mounting it in any desired position upon the stud.

20. In a cutting device, the combination of a bed, and means for pressing material against the surface thereof, said means comprising a plate pivotally mounted with respect to the bed and having a freely-rotatable roller mounted on the active side thereof.

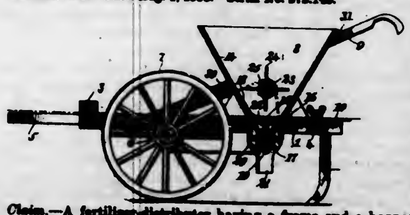
21. In a cutting-machine, the combination of a knife-frame, a bed, and a clamp comprising a concave plate pivoted to the bed and having a roller, said clamp having a depression for the roller and a projection extending from said depression toward a point below the axis of the roller.

22. In a cutting-machine, the combination of a movable knife-frame, a V-shaped bed having a beveled end, and a cross-head adapted to slide over said end.

23. A cutting-machine having a knife-frame, a flat flexible blade and means for bending said blade and securing it to the frame; said means comprising a raised ledge and an edge parallel to the ledge on the frame.

24. A cutting-machine, comprising a knife-frame having an offset blade, and a flat surface located in a different plane from the blade for guiding a sharpening-stone.

810,768. FERTILIZER-DISTRIBUTER. CHARLES K. JOHNSON, Florence, S. C. Filed Aug. 1, 1905. Serial No. 272,145.



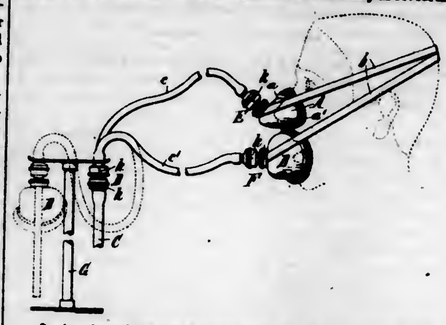
Claim.—A fertilizer-distributer having a frame and a hopper supported thereupon, a feed-plate having openings of different lengths transversely disposed with respect to the direction of advance of the implement, the said plate affording means for closing the lower portion of said hopper, the forward portion of said feed-plate being bent upwardly and lying against the inner face of the wall of said hopper, a feed-roller disposed beneath said feed-opening, means for driving said feed-roller with the advance of said frame, and means for adjusting said feed-plate.

810,769. INHALER. HOWE C. JONES, Westfield, Canada. Filed Nov. 16, 1904. Serial No. 233,204.

Claim.—1. The combination of a mask, and a rim-cushion for the same comprising an elastic rubber annulus which embraces the rim of the mask, and a soft pliable bearing-pad or portion of sponge-rubber permanently attached to said annulus, substantially as set forth.

2. The combination of two separate masks each provided with

inhaling and exhaling valves, and an air and gas mixing valve common to both of said masks and comprising a gas-regulating valve, an air-inlet valve, and an air-regulating valve, substantially as set forth.



3. An air and gas mixing valve, comprising a casing having a connection for a mask at one end and a gas-supply connection at the opposite end, a valve-controlled air-inlet opening, a gas-nozzle projecting beyond said air-inlet opening in the direction of flow of the gas, and parallel rotatable air and gas regulating valves, substantially as set forth.

4. An air and gas mixing valve, comprising a casing having a connection for a mask at one end and a gas-supply connection at the opposite end, and a valve-chamber having an air-inlet, a gas-nozzle projecting into said valve-chamber beyond said air-inlet, a valve in said chamber surrounding said nozzle and controlling said air-inlet, and a rotatable regulating-valve located outside of said valve-chamber and controlling said air-inlet, substantially as set forth.

5. An air and gas mixing valve, comprising a casing having a valve-chamber provided with an air-inlet, a valve which controls said air-inlet and prevents the escape of gas therethrough, a removable cap at one end of said casing having connections for a plurality of tubes, and a removable cap at the opposite end of said casing having a tube connection, said caps being interchangeable, substantially as set forth.

6. An air and gas mixing valve comprising a casing having tube connections at opposite ends, and an air-inlet valve-chamber provided with an air-inlet, a valve in said chamber controlling said air-inlet, said casing comprising two parts, each having a perforated disk, and means connecting said disks and permitting one casing part to be turned relative to the other to regulate the passage of gas through said perforated disks, substantially as set forth.

7. A tubular valve-casing provided with a perforated cross-head and an enlargement having an annular wall provided with openings, a rotatable disk for regulating the passage of gas through said perforated head, an automatic valve controlling the openings in said annular wall, and a rotatable disk for regulating the size of the openings in said annular wall, substantially as set forth.

8. A combined inhaling and exhaling valve comprising a casing having a contracted waist, an inhaling-valve movable in said casing at one side of the contracted waist to control the passage of gas through the casing, and an annular exhaling-valve surrounding said contracted waist and movable to control exhaling orifices in the casing, substantially as set forth.

9. A combined inhaling and exhaling valve comprising a casing, a valve therein controlling the inhaling-passages through the casing, an exhaling-valve carried thereby and controlling the exit from said casing, and rotatable regulating-valves which are turned to vary the area of the inhaling and exhaling passages, said several valves being arranged parallel with each other, substantially as set forth.

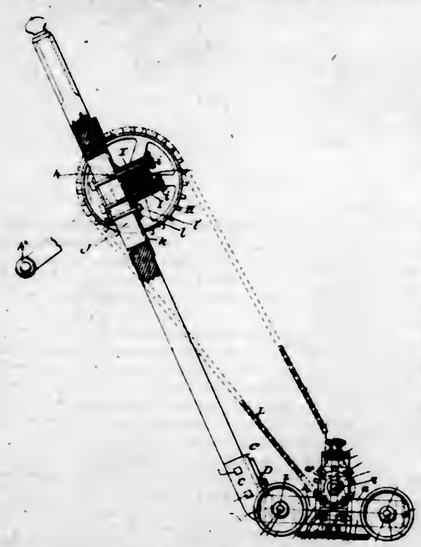
10. The combination of inhaling and exhaling valves, a casing for the same comprising parts separable between said valves, and a receptacle for a volatile anesthetic constructed for attachment to the part of the casing carrying the exhaling-valve, when said other part of the casing is detached, substantially as set forth.

11. The combination of inhaling and exhaling valves, a casing for the same comprising parts separable between said valves, and an open-ended receptacle for a volatile liquid which is constructed to be placed between said parts of the casing when separated and connect them, substantially as set forth.

12. The combination of inhaling and exhaling valves, a casing for the same, comprising parts separable between said valves, an open-ended receptacle for a volatile anesthetic constructed for at-

tachment to the part of said casing carrying the exhaling-valve, when said other part of the casing is detached, and a part constructed to connect said receptacle and said other part of the casing and having valve-controlled air-holes, substantially as set forth.

810,770. MACHINE FOR DRESSING AND FINISHING SURFACES OF FLOORS. JAMES J. KELLY, Albany, N. Y. Filed July 19, 1904. Serial No. 217,206.



Claim.—1. In a machine of the class described, the combination with a main frame composed of two parts hinged together, and formed with grooves, means for locking the two parts together, wheels having axles supported in the grooves, a handle, a supplemental frame carried by the main frame, a revolving floor-dresser, gearing for revolving the floor-dresser, power means on the handle for operating the gearing, and means on the handle for adjusting the power means.

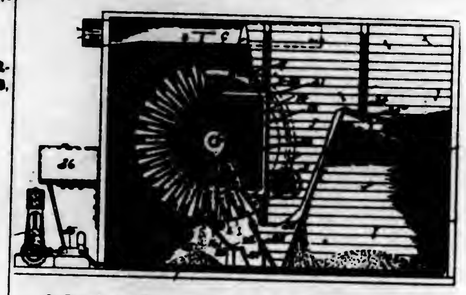
2. In a machine of the class described, the combination with a separable main frame, a detachable supplemental frame carried by the main frame, means for locking the supplemental frame to the main frame, a revolving floor-dresser mounted in the supplemental frame, means for revolving the floor-dresser, supporting-wheels mounted on the main frame, and a handle for guiding the machine.

3. In a machine of the class described, the combination with a main frame made in sections which are hinged together, a supplemental frame supported by the main frame, locking devices for locking the supplemental frame to the main frame, a vertically-movable and rotatable shaft mounted in the supplemental frame, a floor-dressing device carried by the vertical shaft, a spring normally depressing the dressing device, a gear meshing with the gear on the vertical shaft, a handle, and means on the handle for imparting motion to the gear to revolve the dressing device.

4. In a floor-dressing machine, the combination with a frame, a dressing device supported on the frame, gears for operating the dressing device, a handle connected to the frame, means mounted on the handle, for operating the gears, an adjustable support for said means, and a cam for locking the support after it is adjusted.

810,771. DUST-COLLECTOR. EDWARD KING, Jr., Toledo, Ohio. Filed Jan. 27, 1905. Serial No. 242,992.

Claim.—1. In a dust-collector, an open reel or drum having its periphery formed with equidistant bars or slats, an open-meshed fabric covered circumferentially of the reel or drum and having a fold loosely disposed between each pair of bars or slats, a separate radially-movable member loosely engaging the inner extremity of each of said folds, a spring associated with each of said members for normally retaining the engaged fold taut, and a cam member fixed to the axis of the reel or drum for coacting with and imparting an outward radial movement to each of said fold-engaging members at a fixed point in its travel to cause the tension on the fold to be loosened and suddenly renewed for the purpose described.



2. In a dust-collector, an open reel or drum having its periphery formed with equidistant bars or slats, a series of radially-movable rods concentrically secured within the reel or drum in position to radially alternate with the bars or slats, two arms projecting at right angles from each of said rods and in the same plane, an open-meshed fabric secured circumferentially of the reel or drum and having a fold disposed between each pair of rods and loosely looped under the radially-alining rod, means coacting with said arms for normally retaining the folds taut, and a cam member fixed axially within the reel or drum for coacting with and imparting an outward radial movement to each arm at a fixed point in its travel and adapted to permit a sudden return of said arm to its normal position, whereby the associated fold is loosened and suddenly jerked to free itself of accumulated matter.

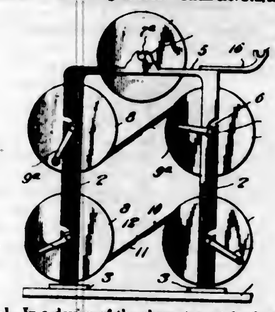
3. In a dust-collector, an open reel or drum having its periphery formed with equidistant bars or slats, an open-meshed fabric secured circumferentially of the reel or drum and having a fold loosely disposed between each pair of bars or slats, a plurality of radially-movable rods loosely engaging the folds of fabric, arms rigidly projecting from said rods at right angles to their body portions and in a radial plane therewith, tension means associated with the arms of each rod for normally holding the engaged fold of fabric taut, and a cam member disposed axially within the reel or drum having an abrupt peripheral depression and coacting with the ends of said arms for causing an outward radial movement of each at a fixed point in its line of travel, whereby the associated fabric fold is loosened and drawn taut for the purpose described.

4. In a dust-collector, a reel or drum comprising end disks and equidistant bars or slats forming the periphery thereof, a pair of axially-arranged concentric flanges secured to the inner faces of the disks and having openings disposed in radial alinement, an open-meshed fabric secured circumferentially of the reel or drum and having a fold loosely disposed between each pair of bars or slats, a separate rod engaging each fold of the fabric and having its extremities bent to project through the alining openings in said flanges, a spring on each bent end of said rods for causing the fabric folds to be normally held taut, and fixed axial cams for engaging the bent ends of the rods and causing each to be radially moved at a fixed point in its revolution to loosen and jerk the engaged fabric fold for the purpose described.

5. In combination, a closed chamber, a rearwardly-slanting partition arising from the bottom of said chamber and having its top terminating below the top of the chamber and formed with a rearwardly-projecting flange, a rotatable dust-collecting mechanism mounted within said chamber in advance of said partition, and a conduit communicating with the upper part of said chamber in position to direct its air-discharge against the rear wall of the chamber by which it is directed down and forward against the partition and around the flange thereon before it is permitted to enter the dust-collector mechanism.

6. In combination, a chamber, a rearwardly-slanting partition arising from the bottom of the chamber and having its top terminating below the top of the chamber and formed with a rearwardly-projecting flange, a rotatable dust-collecting mechanism mounted within said chamber in advance of said partition, a conduit communicating with the upper part of said chamber in position to direct its air-discharge first against the rear wall of the chamber by which it is directed forward against the partition and around the flange thereon before entering the dust-collector mechanism, and means for spraying said partition for the purpose of gravitating a considerable portion of the dust carried by the air-discharge.

810,772. DRUGGIST'S PRESCRIPTION-FILE. ROBERT B. KING, Beaufort, N. C. Filed Aug. 2, 1905. Serial No. 272,488.

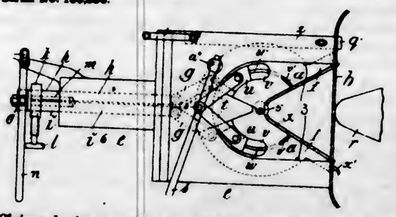


Claim.—1. In a device of the character set forth, the combination of a pair of drums revolubly mounted, a belt or apron carried by one of said drums and adapted to be wound therefrom upon the other drum, and a tape secured to said belt or apron so as to provide a pocket for the reception of a prescription.

2. In a device of the character set forth, the combination of a pair of drums revolubly mounted, a belt or apron carried by one of said drums and adapted to be wound therefrom upon the other drum, and a tape positioned longitudinally upon said belt or apron and secured thereto by means of stitches spaced apart to provide a pocket for the reception of a prescription.

3. In a device of the character set forth, the combination of a pair of drums mounted revolubly and movably, and a belt or apron carried by one of said drums and adapted to be wound therefrom upon the other drum, and a tape secured to said belt or apron by means of stitches spaced apart to provide pockets for the reception of prescriptions.

810,773. APPARATUS FOR BINDING IN THE TOES OF FOOTWEAR. GUSTAF KNOS, Malmo, Sweden. Filed May 9, 1905. Serial No. 259,236.



Claim.—1. An apparatus for binding in the toe-piece of boots and other footwear, comprising a nipper-box *e*, nipper-jaws *f*, to one of which is secured a binding-in cord *b*; mechanism for holding the cord *b* at another point with a regulatable frictional resistance in such a way that on the movement of the nipper-box *e* toward the last *r*, for the purpose of lasting the toe-piece, the cord *b* lays itself with a suitable tension in the working edge of the nipper-jaws *f*, the said jaws having a groove *x* for the reception of said cord; and pushers *u* for driving nails *a* or similar fasteners through the binding-cord *b* and the upper-leather *c* into the lip of the welt *d*, the said nipper-jaws having arcuate grooves *v* in which the said pushers *u* are guided, substantially as described and set forth.

2. In an apparatus for binding in the toe-piece of boots and shoes and other footwear, the combination of a push-rod which is divided longitudinally into two parts *h* and *i*; nipper-jaws *f*; links *g* connecting one end of each of the parts *h i* with one of the nipper-jaws *f* respectively and a set-ring *k* and set-screw *l*, for clamping the other ends of the parts *h i* together in different positions of relative longitudinal adjustment, whereby the nipper-jaws are adjustable for right and left and crooked lasts, substantially as and for the purpose set forth.

3. In apparatus for binding in the toe-piece of boots and shoes and other footwear, the combination of a push-rod which is divided longitudinally into two parts *h* and *i*; nipper-jaws *f*; links *g* connecting one end of each of the parts *h i* with one of the nipper-jaws *f* respectively; each of the parts *h i* having a semicylindrical recess in the other end thereof; a bolt *m* disposed in said recesses; a set-ring *k* and set-screw *l*, for clamping the parts *h i* and the bolt *m* together in different positions of longitudinal adjustment of the parts *h i*, whereby the nipper-jaws *f* are adjustable for right and left and crooked lasts; and operating means connected to the said bolt *m*.

4. In an apparatus for binding in the toe-piece of boots and other footwear, the combination of nipper-jaws *f* to the outer end of one of which is attached a binding-in cord *b*, a clamp *q* for holding the cord *b* at another point, a cam *p* engaging the clamp *q*, and a manually-operated handle 11 for operating the cam *p*, whereby the cord *b* is held with a regulatable frictional resistance.
